Tin mining in the massif may have begun even before the Bronze Age, with a significant number of bronze objects dating from the late Neolithic period having been found in north-west France. The oldest evidence of the use of cassiterite comes from the petrological study of the crucible found at the Early Bronze Age site of Kersulec (Plouneour-Lanvern), in which bronze was produced by mixing grains of alluvial cassiterite directly with copper. Concerning ore extraction, a charcoal-bearing layer containing reduction slags in the Kerveatous valley (Plouarzel) has been dated to Middle/Final Bronze period. Production from this small valley in the early periods is estimated at 20 to 25t of cassiterite.

These first indications show that tin ore from the Armorican peninsula has been mined since the earliest days of bronze production in Western Europe. The considerable tonnages of alluvial ore present in the Brittany's rivers suggest that this region may have been a major production district during the Bronze Age.

4 THE INTRODUCTION OF TIN BRONZE IN THE ARGARIC CULTURE

Lackinger, Aaron (University of Granada) - Montero Ruiz, Ignacio (IH-CSIC) - Murillo Barroso, Mercedes (University of Granada)

The El Argar Culture developed in the southeast of the Iberian Peninsula during the Early and Middle Bronze Age (2200-1550 BC). It is characterised by a standardised material culture, mostly individual and double burials under the dwellings, and a settlement pattern with a predominance of high-rise sites, defensive elements, and an urban layout of terraced buildings with narrow streets, sometimes arranged in artificial terraces. It covers a vast territory, reaching up to 33,000 km² at its peak.

Most of the metal pieces come from funerary contexts, in many cases from ancient excavations. Tin bronzes are in a minority compared to copper and arsenical copper and appear later (after 1800 BC), a time when changes in the material culture also took place, such as the replacement of halberds by swords. The tin bronzes are generally poor and are concentrated in personal adornment items.

The remains of known metallurgical production are scarce, with the sites that have provided the greatest quantity of remains being El Argar (Antas, Almería) and, especially, Peñalosa (Baños de la Encina, Jaén), where information on the complete production sequence has been recovered, although to date, no local production of tin bronze has been documented at any of these sites.

It has been proposed that certain items which, in addition to tin, contain arsenic, could constitute the first evidence of local production of tin bronzes, a view which is reinforced by the isotopic correlation (LIA) of some of them with local copper resources.

The aims of this presentation are to explore this possibility and to fill in its content, in terms of dating, chemical composition and mining resources-tin bronze pieces relationships, via LIA geochemical characterisation.

5 THE INTRODUCTION OF BRONZE IN WESTERN IBERIA: A REVIEW

Figueiredo, Elin (Centre of Materials Research (CENIMAT/i3N), NOVA School of Science and Technology (FCT-NOVA), Lisbon, Portugal)

In western Iberia tin bronze became the primary material for most artefact typologies during the Late Bronze Age (ca. 1250-800 BCE), probably taking a strong advantage on the availability of local tin resources. In the previous periods, such as by Early and Middle Bronze Age (ca. 2250-1800 BCE and 1800-1250 BCE, respectively), bronze was used in some artefact typologies. Additionally, metallurgical remains from some sites indicate that bronze manufacturing was practised at least since the Middle Bronze Age.

In the present communication a state-of-the-art review of the findings concerning the presence and circulation of tin bronze in the Early and Middle Bronze Age in Western Iberia, particularly in present-day Portugal, will be provided. Isolated bronze or tin findings, as well as broad-edged axes of Bujões/Barcelos type which are often associated with the spread of tin bronze in western Iberia, will be presented. At least two sites for tin mining will also be mentioned, along with metallurgical remains such as crucibles containing tin bronze vestiges from the Middle Bronze Age.

6 TIN-BRONZE PRODUCTION BY CO-SMELTING AT THE PHOENICIAN SITE OF EL CARAMBOLO (CAMAS, SEVILLE, SPAIN)

Montero Ruiz, Ignacio (Instituto de Historia-CSIC) - Rovira-Llorens, Salvador (Museo Arqueologico Nacional) - Hunt-Ortiz, Mark (University of Seville)

El Carambolo is one of the most important archaeological sites on the Iberian Peninsula, particularly famous for the fabulous treasure found in it. It dates from the 9th to the 7th/6th century BC. Archaeological work carried out between 2002 and 2005 unearthed a late-period area specialising in metallurgical activities where slag and crucibles from bronze production were collected. Their study has been carried out using SEM and pXRF facilities.

There is little scientific literature on the technology of tin-bronze production. It is too readily assumed that Bronze Age bronze was obtained by alloying copper and tin. However, there is little evidence of the presence of metallic tin before the middle of the 1st millennium BC, despite being Iberia a land with important tin resources. On the other hand, the few analytical studies published so far about Bronze Age and early Iron Age refer to technologies of co-smelting copper minerals with cassiterite or cementation of copper with cassiterite. The slags from El Carambolo are part of this surprising panorama, even more surprising given its late Phoenician affiliation at a time when the Orientalising influence had taken root throughout the southern half of the Iberian Peninsula.

From the analytical study it can be deduced that they are fayalite slags that trap large amount of magnetite crystals as well as metal nodules (copper and bronze ones containing varying percentages of tin). Another characteristic, apparently common to all bronze slags, is the abundance of euhedral tin oxide crystals together with cassiterite grains. It is also common to find relics of unreduced copper ore. These are slags generated in an oxidising-reducing environment compatible with the use of smelting crucibles.

The nature of the copper ore worked suggests that it comes from a zone of supergene enrichment of primary sulphides dominated by chalcopyrite.

988 THROUGH THE LENS OF POTTERY: TECHNOLOGIES IN TIMES OF CHANGE IN PREHISTORIC MEDITERRANEAN BASIN

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Forte, Vanessa (Sapienza University of Rome) - De Falco, Maria (Durham University) - Carloni, Delia (University of Groningen) - Amicone, Silvia (University of Tübingen; University College London) - Bajeot, Jade (Polish Academy of Sciences)

Session format: Regular session

Advances in archaeological science (e.g., aDNA and isotopes analyses) are challenging traditional archaeological narratives and posing new questions especially regarding major transformations in European and Mediterranean societies during prehistoric times. Ceramic is an important component of the material record and gives us insights into cultural, chronological, technological, symbolic and socio-economic information beyond simple chrono-cultural determinations. The combination of stylistic, archaeometric, technological, trace and functional analyses, as well as experimental archaeology, has become established in archaeological research in recent years. At the same time, anthropological, sociological and ethnoarchaeological studies have informed the interpretation of potter's skill and knowledge. This interdisciplinary approach demonstrated to be crucial to detect and explore technical, cultural, symbolic, and socio-economic change. With this in mind, the session aims to bring together a broad range of expertise from archaeological theory, experimental work and the natural sciences, to present research about understandings of periods of change through the lens of ancient ceramic in the Mediterranean basin, from Neolithic to Iron Age.

In particular, we aim to focus on specific questions: What happens to the ceramic production in times of cultural, socio-economic or population transformations? Can periods of change be detected through advanced ceramic analyses? How can these different approaches to ceramics be combined to tackle transitions? What are the mechanisms of resistance and change in contexts of intense socio-cultural innovation? What is the role played by potters' knowledge and skill in these processes?

We welcome studies about the ceramic analyses in times of cultural and socio-economic change with an emphasis on the variety of theoretical and methodological approaches adopted in relation to different contexts and time periods.

ABSTRACTS

1 ADAPTATION OR INNOVATION: VARIABILITY OF CLAY PASTES OF THE EARLIEST POTTERY IN THE SOUTHERN LEVANT (7TH MILL. CAL. BC)

Harivel, Carine (Université Paris Nanterre - ED 395; Technologie et Ethnologie des Mondes Préhistoriques (UMR8068)) - Coquinot, Yvan (Centre de Recherche et de Restauration des Musées de France (C2RMF)) - Eirikh-Rose, Anna (Israel Antiquities Authority) - van den Brink, Edwin C. M. (Israel Antiquities Authority (Ret.)) - Yaroshevich, Alla (Israel Antiquities Authority) - Vieugué, Julien (Technologie et Ethnologie des Mondes Préhistoriques (UMR8068)) - Roux, Valentine (Technologie et Ethnologie des Mondes Préhistoriques (UMR8068))

The first pottery-making societies in the southern Levant appeared in the second half of the 7th millennium cal. BC (Early Pottery Neolithic period), which is relatively late compared to other neighbouring regions. The ceramic assemblages are characterised by a mastery of skills applied to a wide range of functional vessels, as well as by a stylistic variability from which researchers have distinguished three distinct cultural entities: the Yarmukian, the Lodian and the Byblos. This variability is the subject of much debate, as it is interpreted either in chronological or regional terms. Recent technological studies have shown that all the ceramic assemblages from the southern Levant belong to the same technical tradition and are evidence of communities belonging to the same socio-cultural entity. However, this technical tradition, shared by all three cultural entities, is accompanied by some variability in the ceramic clay pastes, not only explained by the intrinsic variability of the raw material.

How can we explain this variability? Is it a variability linked to the different environmental contexts (adaptation process) or is it a cultural variability (inventions) or both? Interpreting the clay paste variability in terms of potter's choice is a first step in investigating the changes observed at the sites. The study analyses the variability of clay pastes in four

sites from neighbouring regions with different geologies and environments: the Jordan Valley and the Jezre'el Valley. The approach includes petrographic and chemical analyses. The main objectives are to characterise the choices made by potters in the selection and processing of raw materials, and to analyse these choices in terms of adaptation and/or invention.

2 CERAMIC TECHNOLOGY AND THE SOCIO-POLITICAL ENVIRONMENT OF PREDYNASTIC EGYPT

Bajeot, Jade (Instytut Kultur Śródziemnomorskich i Orientalnych Polska Akademia Nauk)

This paper aims at presenting the results of the project TECHNOPREGYPT 2021/43/P/HS3/03262, whose purpose is to investigate the modes of pottery production in Predynastic Egypt (4th millennium BCE) to achieve a better understanding of the evolution of the production system during the process of state formation and, consequently, have a better knowledge of the dynamics that led to the birth of the Egyptian state. The chosen method is the technological approach which was applied on pottery from several Egyptian Predynastic sites investigated in the Aswan region by the Aswan-Kom Ombo Archaeological Project, and on the museum collections of the Egyptian Museum, Turin, and of the Museum of National Archaeology, Saint Germain-en-Laye. The analysed material ranges from Naqada IC to Naqada IIIB (c. 3700-3100 BCE) and comes from several domestic and funerary sites of Upper and Middle Egypt.

During the presentation the various identified chaînes opératoires will be illustrated and their evolution and interaction will be followed over time.

Alongside the traditional method adopted to study the ceramic fragments kept in Egyptian storehouses (naked eye and binocular microscope), it was possible to apply X-rays microtomography to a series of samples from the Museum of National Archaeology, Saint Germain-en-Laye. This non-destructive technique allowing to investigate the inner structure of ceramics to highlight the characteristics of the clay paste and the manufacturing techniques is now necessary in the case of complete pots and material from museum collections. The outcomes and potential of this non-destructive analysis will therefore also be shown.

3 CULTURAL IDENTITY WITHIN POTTERY: A GEOCHEMICAL APPROACH TO TRANSITIONAL POTTERY FROM BORDER ZONES IN THE SOUTHERN LEVANT

Coad, Mikayla (University of Oxford)

Tel Burna, Israel is a border site situated between the Israelites, Canaanites, and Philistines. As a border site, Tel Burna offers unique insight into cultural changes over the Late Bronze Age to Iron Age (1550-586 BCE) (LBA-IA) transition in the Southern Levant. The primary objective of this research was to elucidate the markers of cultural identity present within the pottery of the Canaanites and Israelites over a period of cultural change and ethnogenesis in this border zone. This research used a two-part approach of examining specimens using X-Ray Diffraction (XRD) and X-Ray Fluorescence (XRF) to investigate changes in pottery manufacture between the LBA-IA at Tel Burna, while also investigating the presence of surface contamination from deposition on sherd exteriors. Both of these techniques were used to identify any changes in pottery manufacture that may reflect changes in cultural identity, which can be used to understand the transition between the Canaanite and Israelite cultures. There were no trends identified in the XRD and XRF data. The consistency of the data indicates a lack of substantial change in manufacturing techniques from the LBA to the IA. This supports the theory that the emergence of Israelite culture in the Iron Age was a slow development from within the preceding indigenous Canaanite culture. The analysis of the surface contamination present on the sherds was conducted by analyzing both the exterior and the interior of the sherds separately. There were no consistent changes noted between the interior and exterior of each sherd.

4 EXPATRIATE POTTERS, EGYPTIAN TECHNOLOGIES, AND CULTURAL TRANSFERENCE IN THE CERAMIC ASSEMBLAGE AT JAFFA IN CANAAN

Pierce, Krystal (Brigham Young University)

The Late Bronze Age and early Iron Age site of Jaffa in the Levant features a fortress that contained large amounts of Egyptian and Egyptian-style material culture, including a ceramic assemblage that is one of the largest early collections of this corpus type in the Levant. These vessels were utilized by Egyptian expatriate administrative and military personnel, who played an authoritative role in the settlement during the New Kingdom period of Egyptian hegemony in Canaan. The ceramic assemblage at Jaffa includes some high value vessels directly imported from Egypt; however, the bulk of the corpus consists of quotidian vessels that were locally produced using regional clays and materials, but with Egyptian manufacturing technologies that differed from local Canaanite techniques. A thorough examination of the manufacturing technologies of the assemblage demonstrates that the potters had a detailed and intricate knowledge and understanding of the Egyptian New Kingdom ceramic industry, demonstrating that these potters were either Egyptians themselves or had been professionally trained in Egyptian techniques. After the Egyptians retreated from Jaffa and the Egyptian-style pottery disappears from the site, some of these Egyptian technologies began to

appear in the Canaanite ceramic corpus. In this paper, the ceramic assemblage from Jaffa will be analyzed in terms of Egyptian manufacturing technologies, including morphology, fabric, temper, firing procedures, production techniques, surface treatment, and decorative elements, in order to understand the impact of Egyptian expatriate potters and cultural transference of technology into the Canaanite tradition.

5 THE POTS INSIDE THE POT. GROG TEMPER AS A PROXY OF TECHNOLOGICAL CHANGES DURING THE CHALCOLITHIC PERIOD IN SOUTHERN ROMANIA

Opris, Vasile (Research Institute of the University of Bucharest (ICUB), Archaeosciences Platform; Bucharest Municipality Museum) - Stoicescu, Daniel (Research Institute of the University of Bucharest (ICUB), Archaeosciences Platform) - Fehér, Kristóf (Hungarian National Museum, National Institute of Archaeology, Archaeometry Laboratory) - Manea, Bogdan (Research Institute of the University of Bucharest (ICUB), Archaeosciences Platform) - Dumitrescu, Sebastian (Research Institute of the University of Bucharest (ICUB), Archaeosciences Platform) - Balázs, Henriett (Hungarian National Museum, National Institute of Archaeology, Archaeometry Laboratory) - Lazar, Catalin (Research Institute of the University of Bucharest (ICUB), Archaeosciences Platform) - Kreiter, Attila (Hungarian National Museum, National Institute of Archaeology, Archaeometry Laboratory)

The intensive use of grog-tempered pottery in the Lower Danube region began around 5200/5000 BCE, marking a significant shift from the earlier Neolithic practices of incorporating organic and/or mineral tempers into the pottery clay matrix. The transition appears to be diachronic and exhibits local characteristics, with limited knowledge regarding the origin, dispersion, and intensity of this technological practice.

Firstly, the aim of our presentation is to frame the Chalcolithic grog-tempered pottery from Southern Romania in this general context, by presenting data on clay tempering practices collected from various sites in the region dated during the fifth millennium BCE.

Secondly, our attention will be directed towards the specific case of grog-tempered ceramics found at the renowned Gumelnița site, where extensive research has been conducted on both Early and Middle Chalcolithic habitation layers in recent years. The selection for laboratory measurements was based on the outcomes of macroscopic and microscopic analyses, encompassing at least one representative from each fabric sub-type. Employing archaeometric methods, specifically thin-section petrography and SEM-EDS, we developed and applied an analytical protocol. This protocol involves a meticulous examination of the pottery matrix and all grog inclusions within the section, proving to be a time-consuming yet highly effective method for characterizing the technological features of both the grog inclusions and the pottery matrix.

The work of VO is supported by a fellowship within the Research Institute of the University of Bucharest (ICUB) under the project "The rise and fall of the grog-tempered pottery in the Southern Romania during the Chalcolithic period (5th millennium BCE)". The work of DS, BM, SB and CL is supported by a grant of the Ministry of Research, Innovation, and Digitisation, contract number 41PFE/30.12.2021, within PNCDI III.

6 FROM WATER TO FIRE: AN ARCHAEOMETRICAL INVESTIGATION OF SHELL-TEMPERED CHALCOLITHIC POTTERY FROM THE ARCHAEOLOGICAL SITE OF SĂVENI-LA MOVILE

Manea, Bogdan (Archaeosciences Platform, Research Institute of the University of Bucharest (ICUB), Romania; Interdisciplinary School of Doctoral Studies, University of Bucharest, Romania) - Stoicescu, Daniel (Archaeosciences Platform, Research Institute of the University of Bucharest (ICUB), Romania; Doctoral School of Physics, Faculty of Physics, University of Bucharest, Romania) - Dimofte, Daniela (Faculty of Geology and Geophysics, Department of Mineralogy, University of Bucharest, Romania) - Vlad, Florin (Ialomița County Museum, Slobozia, Romania) - Tiseanu, Ion (National Institute for Laser, Plasma and Radiation Physics, Bucharest, Romania) - Radu, Valentin (Archaeosciences Platform, Research Institute of the University of Bucharest (ICUB), Romania; National Museum of Romanian History, Bucharest, Romania) - Lazăr, Cătălin (Archaeosciences Platform, Research Institute of the University of Bucharest (ICUB), Romania)

The Săveni-La Movile archaeological site is located on the high terrace of the Ialomița River in the southern Bărăgan Plain, near the Săveni commune (Ialomița County), Southeast Romania. Excavations here revealed the presence of a Cernavodă I settlement (4th millennium BC), a phase distinguished by the addition of crushed shells into pottery, a technological feature that is different from those previously observed within Chalcolithic communities in the Muntenia region.

The current presentation will share some preliminary results of an archaeometrical analysis conducted on Late Chalcolithic Cernavodă I pottery fragments from the Săveni-La Movile site.

By involving a variety of research methods, including macroscopic investigation, thin-section petrography (coupled with malacology), X-ray CT scanning, Scanning Electron Microscopy (SEM), and experimental archaeology, various technological aspects of these shell-tempered pottery have been analysed.

The study provides information on the nature of the shells (fossil vs non-fossil), their presence (natural vs deliberate), morphology, dimensions, frequency, distribution, orientation (preferential vs non-preferential), firing parameters, potential species, and provenance. All the obtained data about species and provenance will be correlated with the aquatic faunal remains from the settlement, enabling insights into the practicality of these people through the recycling or non-recycling of household waste.

Ultimately, by integrating the findings of this study within a broader geographical and chronological perspective, we anticipate that this research will yield a better understanding of technologies and human-environment interactions during prehistory.

This work was supported by the Interdisciplinary School of Doctoral Studies of the University of Bucharest, Romania, and by a grant from the Ministry of Research, Innovation, and Digitization, contract number 41PFE/30.12.2021, within PNCDI III.

7 POTTERY FINDS OF VUČEDOL AND LJUBLJANA CULTURES OF THE 3RD MILLENNIUM BC IN CENTRAL SLOVENIA: A TYPOCHRONOLOGICAL AND ARCHAEOMETRICAL APPROACH

Leghissa, Elena (ZRC SAZU, Institute of Archaeology) - De Min, Angelo (Department of Mathematics, Informatics and Geosciences, University of Trieste) - Kasztovszky, Zsolt (Nuclear Analysis and Radiography Department, HUNREN Centre for Energy Research) - Szilágyi, Veronika (Nuclear Analysis and Radiography Department, HUNREN Centre for Energy Research) - Velicogna, Matteo (Department of Mathematics, Informatics and Geosciences, University of Trieste) - Vinazza, Manca (Department of archaeology, University of Ljubljana) - Bernardini, Federico (University Ca'Foscari Venezia; Multidisciplinary Laboratory, The "Abdus Salam" International Centre for Theoretical Physics)

The Ljubljansko barje region in central Slovenia during the late Copper Age (first half and middle of the third millennium BC) exhibits two distinct cultural phases. The earlier phase is associated with the Vučedol culture, while the later phase is marked by the emergence of the Ljubljana culture. Despite notable disparities in vessel forms and decorative techniques between the two cultures, a notable continuity suggests a strong influence of the Vučedol culture on the later settlement of the Ljubljansko barje during the Late Copper Age.

The pile-dwelling sites within the Ljubljansko barje region, attributed to the Ljubljana Culture, have yielded a diverse array of artefacts. These include finely crafted vessels decorated with barbed-wire decoration, typical of the Ljubljana Culture, as well as common ware resembling vessels from the Somogyvár-Vinkovci Culture. This study focuses on five contemporaneous sites: Dežman's pile-dwellings near Ig, Parte, Špica, Založnica, and Dušanovo pile dwellings, as part of the postdoctoral project "Exchange and mobility dynamics at Ljubljansko barje: The Late Copper age pile-dwelling Špica in Ljubljana." Material from these sites underwent archaeometric investigations conducted by an international team from Slovenia, Italy, and Hungary.

At the EAA conference, we will present comparative archaeometric analyses conducted using PGAA and optical microscopy techniques. The obtained data aim to elucidate the relationship between the Vučedol culture and the Ljubljana culture, as well as the interactions among contemporary sites from the middle of the third millennium BC.

8 CONTINUITY AND INNOVATION IN POTTERY TECHNOLOGY: THE KARST REGION FROM NEOLITHIC TO EARLY BRONZE AGE

Bernardini, Federico (University Ca' Foscari Venice; The Abdus Salam international Centre for Theoretical Physics) - Leghissa, Elena (ZRC SAZU, Institute of Archaeology)

The paper presents the findings of an interdisciplinary project exploring the development of pottery technology in the Trieste Karst region (northeast Italy) from the Neolithic to the Early Bronze Age (EBA). It also seeks to identify cultural links with other areas by examining potentially imported vessels. This research builds upon a long-term investigation into lithic raw materials used to craft polished stone axes in the Caput Adriae, aiming to enhance our understanding of the primary exchange networks operating during this period.

Archaeometric analyses, alongside a traditional typological examination, reveal significant differences between Neolithic ceramics (traditionally linked with the Danilo-Vlaška group) and the majority of Late Copper Age (LCA)/Early Bronze Age (EBA) pottery (usually primarily associated with the Ljubljana culture and a few with the Cetina culture). Neolithic pottery displays consistent characteristics across all vessel types, including coarse grain, prevalent sparry calcite temper, and the absence of grog. In contrast, most LCA and EBA vessels exhibit distinct features such as very fine-grained paste, no sparry calcite, notable use of grog temper, higher quartz and flint content, and relatively frequent muscovite occurrence in the matrix. Notably, from a technological perspective, the analysed Cetina vessels bear strong resemblance to the majority of LCA ceramics.

Certain potsherds attributed to the Ljubljana culture may not have been locally produced, given their mineralogical and petrographic composition, along with strong cultural ties to the Ljubljansko barje during the mid-3rd millennium

BC. Ongoing archaeometric studies on ceramics from the core area of the Ljubljana culture may facilitate comparison, revealing whether the Karst region and present-day Central Slovenia not only shared robust cultural connections but also exchanged ceramics alongside metal and stone artefacts.

9 NEOLITHIC POTTERY TRADITIONS IN THE ADIGE VALLEY: NEW DATA FROM RIPARO GABAN AND LA VELA (NORTH-EASTERN ITALY)

Deimichei, Giulia (Archaeometry Research Group, Eberhard Karls University of Tübingen; LaBAAF - Laboratorio Bagolini Archeologia, Archeometria, Fotografia, Dipartimento di Lettere e Filosofia, Università di Trento) - Amicone, Silvia (Archaeometry Research Group, Eberhard Karls University of Tübingen; Institute of Archaeology, University College London) - Armellini, Jacopo (Departament d'Història, Geografia i Art, Facultat de Ciències Humanes i Socials, Universitat Jaume I, Castelló de la Plana) - Pedrotti, Annalisa (LaBAAF - Laboratorio Bagolini Archeologia, Archeometria, Fotografia, Dipartimento di Lettere e Filosofia, Università di Trento)

The transition between the Early and Middle Neolithic in Trentino (north-eastern Italy) is marked by social changes well-reflected in a shift to a fully farming economy, that correspond to the emergence of the so-called Square-Mouthed Pottery Culture (SMP). The Neolithic pottery assemblages of the Adige valley hold great potential to shed new light on the developments that marked this period in north-eastern Italy.

This study focuses on the technological analysis of pottery from Riparo Gaban and La Vela – VII; these are key sites for the understanding of the Neolithic chrono-cultural sequence of the Adige valley. Riparo Gaban is a rock-shelter characterized by the presence of pottery attributed to the Gaban group, the first Neolithic evidence in the Adige valley (5200-4700 BCE).

La Vela is an open-air site, surrounded by a ditch, whose Early Neolithic layers are marked by the presence of pottery that can be related to the Gaban group (5000-4700 BCE) and by the appearance of the SMP Culture (4800-4300 BCE) during the Middle Neolithic.

Ceramic samples representing different fabrics and different chronological phases were selected from both sites, together with geological specimens collected in the Adige valley. These samples were studied with an integrated archaeometric approach including ceramic petrography and X-ray diffraction. Emphasis was placed on tracing phenomena of continuity and change in pottery raw material procurement strategies at the time of the emergence of the SMP material culture.

The results highlight a great variability in the choice of raw materials, reflecting a know-how of the various natural resources present in the area. They also reveal interesting phenomena of continuity and change in the selection and processing of raw materials over the timespan considered, that will be discussed in the framework of the important social developments that took place at that time.

10 EXPLORING CULTURAL PROCESSES THROUGH CERAMIC PRODUCTION: A CASE STUDY FROM CAMPANIA, SOUTHERN ITALY, DURING THE 3RD MILLENNIUM BC

De Falco, Maria (University of Modena and Reggio Emilia, Department of Chemical and Geological Sciences)

The aim of this paper is to analyse the relationship between ceramics and cultural processes taking place in Campania, and broadly in the Italian Peninsula, during the 3rd millennium BC. In particular, I draw new inferences from the ceramic production by using a holistic approach that integrates the typological and stylistic analysis, typical of Italian tradition, with a theoretically informed broader chaîne opératoire approach involving macroscopic observations and archaeometric analyses on a completely new dataset.

The 3rd millennium BC is characterised at European scale by the intense circulation of people, objects, models and ideas, as well as by significant innovations. In this framework, important cultural and socio-economic changes occur in Southern Italy and especially in Campania: large and structured settlements start to occupy plains as well as internal areas; complex collective funerary practices are substituted by large cemeteries of single graves; 'foreign' influences from Europe and the Mediterranean (e.g., the Bell Beaker phenomenon) impact the local communities in different ways, displaying diverse degrees of permeability and local adaptation across Copper Age periods.

These important socio-economic changes occurring in Southern Italy during the 3rd millennium BC resulted in radical changes in the production and purpose, and symbolic and material value, of ceramic objects. Through a comprehensive program of macroscopic and archaeometric analyses on four multi-phased key sites, this paper addresses continuities and discontinuities in the technological choices of Copper Age Campanian communities and possible drivers behind long term technological change. In particular, a shift in the demand for ceramic production, embedded in the cultural processes ongoing in this period, is proposed to explain the significant changes occurring in the ceramic repertoire and productive process.

11 INQUIRING SAMENESS AND DIFFERENCE IN EARLY TO LATE COPPER AGE POTTERY PRODUCTION: EXAMPLES FROM THE GROTTA DI SANT'ANGELO (CALABRIA, ITALY)

Carlioni, Delia (Groningen Institute of Archaeology, University of Groningen, Netherlands; Centro di Ricerca speleo-archeologica 'Enzo dei Medici', Italy) - Larocca, Felice (Gruppo di ricerca speleo-archeologica, Università degli Studi di Bari Aldo Moro, Italy; Centro di Ricerca speleo-archeologica 'Enzo dei Medici', Italy) - Pacciarelli, Marco (Università degli Studi di Napoli Federico II, Italy) - Attema, Peter (Groningen Institute of Archaeology, University of Groningen, Netherlands) - De Benedetto, Giuseppe (Dipartimento di Beni Culturali, Università del Salento, Italy)

The Copper Age in Italy (3700-2200 BC) denotes a period in which major socio-economic and cultural transformations took place and marked the shift from Neolithic to Bronze Age societies. In the course of the 4th and 3rd millennia BC the material culture constantly changes, and complex dynamics of interrelationships appear on both regional and extra-regional scales. Pottery stylistic variations mirrored these transformations in a way that is only partially understood and served as the cornerstone for the definition of distinct chronological phases. Archaeological sites with ceramic assemblages that cover the entire Copper Age time span are rare but represent case studies of crucial importance. As a matter of fact, such kind of contexts allow to observe continuity and discontinuity among communities that inhabited the same territory and likely exploited the same environment. The underground archaeological deposit at the Grotte di Sant'Angelo (Cassano allo Jonio, Calabria) includes a ceramic assemblage that covers all the phases defined for the Copper Age in Calabria region, testifying to the wide circulation of cultural models occurred during the 4th and 3rd millennia BC. This paper inquires sameness and difference in stylistic, technological, and functional aspects of Early to Late Copper Age pottery production at example of the Grotte di Sant'Angelo archaeological context. The combination of typological, traceological, petrographic, and organic residue analysis revealed to be a successful investigation strategy and allowed to look at pottery materials beyond the simple need for chrono-cultural determinations. This case study contributes to the wider research on the definition and the understanding of the changes that featured the Copper Age in the central Mediterranean basin.

12 PERSISTING WITHOUT CHANGE: CONSISTENCY OF POTTER'S PRACTICES AT LIPARI

Levi, Sara Tiziana (Dip. di Scienze Chimiche e Geologiche, Un. di Modena e Reggio Emilia; Institute for the Study of the Ancient World, New York University, NY, USA) - Cannavò, Valentina (Dip. di Scienze Chimiche e Geologiche, Un. di Modena e Reggio Emilia) - Brunelli, Daniele (Dip. di Scienze Chimiche e Geologiche, Un. di Modena e Reggio Emilia) - Di Renzoni, Andrea (Istituto di Scienze del Patrimonio Culturale - CNR, Montelibretti (RM)) - Bettelli, Marco (Istituto di Scienze del Patrimonio Culturale - CNR, Montelibretti (RM)) - Martinelli, Maria Clara (Parco Archeologico delle Isole Eolie, Museo Luigi Bernabò Brea, Lipari (ME))

At Lipari the ceramic production of Impasto pottery during prehistoric and protohistoric times is characterized by a strong tradition and continuity in the selection and preparation of the raw materials.

A single main local fabric -with volcanic glass and pumice- remains practically unchanged for 5000 years, showing an impressive consistency and standardization. The same "recipe" is used for the manufacture of pots of various shapes, dimensions and functions.

Major innovations in the ceramic pastes of Impasto pottery are only attested in two phases (1) during the Late Neolithic to produce the red monochrome Diana ware (2) during the second half of the protohistory when the local components are mixed with clay imported from Sicily.

This strongly conservative tradition is in contrast with the marked stylistic differences that reflect the complex events of the island characterized by multiple cultural contacts and demographic changes during the prehistory and protohistory.

The standardization and continuity at Lipari is unique compared to the pottery assemblages of other contexts in the Aeolian Islands and elsewhere, analyzed with the same methodologies (petrographic analysis and classification).

13 CRAFTING RESILIENCE: PERSISTENCE AND ADAPTATION OF THE CERAMIC MANUFACTURE AT ROCA VECCHIA FROM THE MIDDLE TO THE FINAL BRONZE AGE PHASES

Mentesana, Roberta (Cultura Material i Arqueometria UB (ARQUB, GRACPE), Dept. d'Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona, Catalonia, Spain) - Iacono, Francesco (Dipartimento di Storia Culture Civiltà, Università di Bologna, Italy)

Through the second millennium BC, Bronze Age communities of Southern Italy have shown a remarkable degree of resilience in coping with changes in cultural interaction and the landscape. The site of Roca (Melendugno-Lecce, IT) located on the coast of modern-day southern Italy hosted one of the most important Bronze Age communities in the Central Mediterranean, and experienced a complex history including phases of violent destruction and rebuilding phases, in a moment when the long-range connection with the Aegean world was at their historical peak. Roca was

also part of a broad landscape that has only now become accessible to being analysed thanks to the results of the Roca Archaeological Survey (RAS), the first systematic archaeological survey focusing on the hinterland of the site.

Through the analysis of ceramics coming from the Middle to the Final Bronze Age at the site and from the survey campaign, in this presentation, we will explore how changes in the complex history of the settlement and the surrounding landscape are matched in technological choices operated by the local community responsible for the production of impasto pottery. Ceramics were analysed using ceramic petrography and scanning electron microscopy to observe technological change occurring in fabrics and firing strategies along the phases.

The study already revealed consistent technological choices over the phases along with a later introduction of a new fabric with very different characteristics. These results brought us to reconsider resource availability and appropriation in the landscape surrounding the site of Roca. We will discuss the manufacturing choices for ceramics production present at the site compared with those of the survey material to reconstruct the manufacturing landscape around the site of Roca and whether it could be potentially linked to broader resilience strategies in the area.

14 **AN EARLY IRON AGE FORMAL VESSEL IN REDUCTIONIST FOCUS: FROM PETROGRAPHY AND CHEMISTRY TO EXPERIMENTAL REPLICATIONS, ORGANIC RESIDUES ANALYSIS AND CONTEXTUAL SYMBOLISM**

Vidale, Massimo (University of Padova) - Maritan, Lara (Department of Geosciences, University of Padova) - Pérez-Monserrat, Elena Mercedes (Department of Geosciences, University of Padova) - Pecci, Alessandra (Institut d'Arqueologia, Equip de Recerca Arqueològica - Arqueomètrica de la Universitat de Barcelona (ERAAUB, IAUB, INSA-UB)) - Baratella, Vanessa (Department of Cultural Heritage: Archaeology, History of Art, of Cinema and Music, University of Padova) - Giunto, Andrea (Department of Cultural Heritage: Archaeology, History of Art, of Cinema and Music, University of Padova) - Adesso, Francesca (Department of Cultural Heritage: Archaeology, History of Art, of Cinema and Music, University of Padova) - Famari, Valentina (Department of Cultural Heritage: Archaeology, History of Art, of Cinema and Music, University of Padova) - Forte, Vanessa (Department of Sciences of Antiquities, Sapienza University of Rome)

The production of ceramic drinking sets is well attested in the craft sector of Padova in the VIIIth century BCE, possibly in the framework of a substantial use of alcohol in banquets and meetings for building political consensus. "Situliform" vessels - tall truncated-cone vessels formally similar to bronze buckets - are prominent in elite funerary furnishings of the early Iron age of the Veneto Region (VIIIth-VIIth centuries BCE). Well recognized fragments are also found in dwelling contexts pertaining to the earliest wave of local urbanization. In spite of the relevance of the ceramic type, the involved techniques of production, objectual meaning and functions are still unknown, even though it is common archaeological sense that "situliforms" were used to present and serve special beverages during feasts and formal ceremonies in general. In order to gain insight on the entangled meanings of this type, multiple scientific investigations (petrography, XRD, XRF, SEM-EDS, experimental replicas of the forming process, GC-MS, 3D digital modelling) were applied to a specimen from a micro-stratified context excavated in the centre of Padova (securely dated by ¹⁴C to the second half of the VIIIth century BCE). The use for serving special, millet-based drinks is confirmed. Beyond the contingencies of materiality, it seems possible to glimpse some important symbolic implications of the ceramic type, both in the context of primary use and recycling in a technical environment completely different from the original one.*

* This research was funded by the Progetto di Eccellenza CA.RI.PA.RO. "La prima fonderia di Padova preromana - The earliest foundry of pre-Roman Padua".

15 **POTTERY AS A TRACKING TOOL FOR SOCIAL TRANSFORMATIONS THROUGH TIME. THE EVOLUTION OF NEOLITHIC OCCUPATIONS IN COVA GRAN (5200-1300 CALBCE)**

Rodríguez Pérez, Cèlia (Universitat Autònoma de Barcelona) - Martínez-Moreno, Jorge (Universitat Autònoma de Barcelona) - Mora Torcal, Rafael (Universitat Autònoma de Barcelona) - González Marcén, Paloma (Universitat Autònoma de Barcelona)

Prehistoric ceramics offer many approaches to analysis which have multiplied in recent years thanks to the introduction of new methodologies. In this work, the Neolithic occupations of Cova Gran de Santa Linya (Spain) were investigated using a typological and morphological study of the ceramic assemblage to characterize this type of product and propose their chrono-cultural assignment. In this approach, special emphasis has been placed on aspects of taphonomy aimed at evaluating processes related to the ceramic's erosion and fragmentation, in which refitting is applied to evaluate its spatial dispersion.

These taphonomic attributes on ceramics inform about the formation processes of the archaeological record, which both complement and can be contrasted by the information derived from typological indicators. The combination of

taphonomic and typological analyses on the ceramic assemblage from Cova Gran can help us unravel the apparent contextual chaos in the palimpsest of Neolithic archaeological unit 3N.

Level 3N presents a layer of pen deposits under which hearths, pits, and post holes are detected. These usually super-imposed archaeological structures generate a palimpsest that is difficult to read temporally and socially. The typological, morphometric, and taphonomic study of the ceramic group assists in defining a sequence of archaeological events that delineate various patterns of occupation of that space for almost 4,000 years.

Throughout the Neolithic, the Cova Gran has maintained uses related to the socio-economic organization of these groups, such as habitat, storage, and stabling of ovicaprines. The ceramic productions of these phases indicate important changes in the management of the use of the rock shelter of a temporal range between 5200-1300 CalBCE. Our approach suggests the interest in combining pottery typology, morphometry, and taphonomy to address the study of palimpsests by allowing us to propose changes in the orientation of the socio-economic organization during the Neolithic.

16 **HOW TO DEAL WITH THE CHANGE: POTTERY MANUFACTURE AND CONSUMPTION CHOICES IN SOUTHEAST IBERIA DURING THE POST-ARGARIC PERIOD**

López-López, Alberto (Universidad de Murcia)

The so-called Post-argaric period in Southeast Iberia (1550/1500 - 1350/1300 BC) is a transitional period between Argaric Bronze Age and Late Bronze Age. Concerning pottery, new types and decorative styles appeared and exchange networks became broader. The presence of Central Iberian and Mediterranean ceramics reveals the existence of long-range circuits, although some scholars conceive that ceramic production was not a specialised activity for this period. However, there are no in-depth research on ceramic assemblages of the period to accurately assess these issues.

This study aims to combine archaeological and archaeometric (thin section petrography, XFR, TG) techniques in order to define technological patterns, recipes and, in short, technical and technological traditions, as well as their (dis)continuities throughout the period. These results allow us to focus on productive and consumption choices regarding the vessels, which also leads us to explore exchange networks. For this purpose, the archaeological site of Murviedro (Lorca, Murcia) has been selected, whose excavation revealed two Post-argaric Bronze Age phases, making it a unique case study in the region. Considering that pottery manufacture is usually conservative, this theoretical and methodological approach will provide insights about:

1. How pottery manufacture changed or persisted in a time of deep social, economic and territorial transformations.
2. How potters and consumers dealt with new productions, and the choices they made in order to resist or accept change.
3. Potential and limitations of the methodological approach used.

17 **CULTURAL EXCHANGE AND POTTERY DYNAMICS: INSIGHTS FROM EARLY IRON AGE CERAMICS FROM LA FONTETA (SE IBERIA, 8TH - 6TH CENTURIES BC)**

del Pino Curbelo, Miguel (Universidad de Las Palmas de Gran Canaria) - Lorrio Alvarado, Alberto (Universidad de Alicante) - López Rosendo, Ester (Universidad de Alicante) - Torres Ortiz, Mariano (Universidad Complutense de Madrid)

The first millennium BC represents the final chapter of prehistoric times in various regions across the Mediterranean. In southern Iberia, these transformative shifts were instigated by the interaction between local communities and Phoenician settlers along the coast.

The advent of new trade routes, combined with the adoption of unfamiliar domestic species and advanced craft techniques, exerted significant influence on the evolution of daily life and institutional frameworks in Iberia, particularly from the 8th century BC onwards. The establishment of numerous coastal settlements, specializing in the intensive exploitation of local resources, facilitated the proliferation of distinct transport vessels, emblematic of a burgeoning pottery industry. Commodities like olive oil and wine, acting as catalysts for social change within local societies, were not only consumed locally but also traded with other colonial outposts.

Despite these developments, key aspects surrounding the establishment of pottery workshops, their integration with local artisanal traditions, and the distribution networks for their products remain poorly understood, especially following the latter half of the 8th century BC, when certain Phoenician settlements along the Andalusian coast achieved full maturity. Nonetheless, the economic landscape underwent significant transformations during the 7th and 6th centuries BC, evidenced by changes in typology and localized economic patterns.

This research presents an analysis of Early Iron Age amphorae (n=38) unearthed at the colonial settlement of La Fonteta (Alicante, Spain), with a chronology spanning from 8th to 6th centuries BC. The examination encompasses comparison with reference materials from Mediterranean workshops, as well as handmade ceramics recovered from

La Fonteta (n=9) and the nearby settlement of Peña Negra (n=36). The findings illuminate a great diversity of origins for La Fonteta, encompassing both Iberian and Mediterranean sources. Furthermore, connections with handmade wares from Peña Negra suggest the potential involvement of local populations in the adoption of emerging technological practices.

18 CERAMICS AND CULTURAL CHANGE IN 7TH CENTURY BC CRETE: THE POLYCHROME VESSELS FROM KNOSSOS

Kotsonas, Antonis (New York University) - Klesner, Catherine (University of Cambridge)

The Cretan polychrome vessels of the 7th century BC, though acknowledged as “bold and original creations of ceramic art” and featured in textbooks of Greek art and Greek pottery handbooks, have been subject to inadequate research. Found primarily at Knossos, in collective chamber tombs, they comprise neckless storage vessels and lids adorned with orientaling (including figural) decoration. This ware emerged during a period of heightened cultural and socio-economic interaction across the Mediterranean. Although it can be shown to have developed through the experimentation of Knossian potters, the inspiration for the ware has been sought in both local and non-local sources, including Minoan art, and Cypriot and/or Philistine bichrome pottery. Nevertheless, the potential influence of wall-painting of the 7th century BC remains unexplored.

Through non-destructive compositional and mineralogical analyses of 24 fragments of polychrome jars and lids, from eleven tombs excavated in different burial areas around Knossos, we have reconstructed some of the key aspects of the polychrome jars chaîne opératoire to evaluate previous hypotheses on the relation of this ware with other polychrome wares from the Aegean and Cyprus. The identification of two different types of white ground and a novel blue pigment lends analytical support to the empirical conclusion that the technique arose from local experimentation and emulation of imported goods, and undermines the possibility of direct knowledge transfer from abroad. The paper also addresses questions over the social significance of the innovation in this ware, the relatively short period of its production, and its nearly exclusive attestation in burial contexts at Knossos. More broadly, we reflect on the ways in which the introduction of Cretan polychromy relates to the integration of the island into broader Mediterranean networks, and we associate its demise with broader patterns of cultural change that swept Crete in the late 7th century BC.

995 SENSE AND SUSTAINABILITY IN FORAGING COMMUNITIES

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Bentsen, Silje (Nordland County Council; University of the Witwatersrand) - Grimm, Sonja (Zentrum für Baltische und Skandinavische Archäologie (ZBSA))

Session format: Session with presentation of 6 slides in 6 minutes

Palaeolithic and Mesolithic societies are characterized by remarkable adaptability and resilience in the face of environmental challenges. Our 2022 discussion session about the contribution of prehistoric experiences to current debates showed that this topic evokes intense discussions in our community. Therefore, we examine in this discussion session evidence for sustainability, resilience, adaptability, and change management within foraging societies from deep past to historic times. How did hunter-fisher-gatherers sense and make sense of the changes in their environment? How did they manage their resources, adapt to changing environments, and implement strategies for survival and growth? What were their strategies for shifting climates, resource constraints, and evolving social dynamics? From the answers, we can draw inspiration and valuable lessons, that can be gleaned from our ancestors, for addressing contemporary global challenges.

Key topics to be discussed in this session include:

Sustainable Resource Management: How did Palaeolithic, Mesolithic, and later foraging societies acquire, utilize, and conserve critical resources such as food, water, and materials? What can this teach us about sustainable practices today?

Technological Adaptations: Which innovations in tools and technologies allowed early humans to thrive in various landscapes? What are the implications for modern technological adaptation in the face of challenges like climate change?

Social and Cultural Strategies: Which roles do social structures, knowledge sharing, and cultural practices play in enabling hunter-fisher-gatherer communities to respond to environmental shifts and challenges?

Resilience and Change Management: How did foragers adapt to abrupt environmental changes and which relevance do their strategies have for modern change management and resilience-building efforts?

We aim to foster a rich dialogue among experts and attendees and invite thought-provoking contributions from Palaeolithic, Mesolithic, and/or ethnoarchaeological research (6 min./ 6 slides) to spark a stimulating discussion that

bridges the gap between prehistoric and modern sustainability, resilience, adaptability, and change management practices.

ABSTRACTS

1 ADAPTATION STRATEGIES OF EARLY TO MID-HOLOCENE HUNTER-GATHERERS IN THE NON-AQUATIC SAVANNAH ENVIRONMENT OF NW BUTANA, SUDAN

Varadzin, Ladislav (Institute of Archaeology of the CAS, Prague, Ladislav Varadzin) - Varadzinová, Lenka (Czech Institute of Egyptology, Faculty of Arts, Charles University, Prague, Czech Republic) - Juříčková, Lucie (Department of Zoology, Faculty of Science, Charles University, Prague, Czech Republic) - Hošek, Jan (Czech Geological Survey, Prague, Czech Republic) - Hošková, Kristína (Institute of Archaeology, Czech Academy of Sciences, Prague, Czech Republic) - Kapustka, Katarína (Institute of Archaeology, Czech Academy of Sciences, Prague, Czech Republic)

This presentation will contribute to the discussion on the sustainability of prehistoric hunter-gatherers facing environmental risks using data from the Shaqadud Archaeological Project (since 2019) and Butana Archaeological Project (from early 1980s) focusing on what is today a vast dry savannah in the NW Butana, Sudan, in the easternmost Sahel. Our project investigates the adaptation and resilience strategies of prehistoric hunters-gatherers in inland areas between 11.7 and 6.7 ka where cultural resilience was much more difficult for foraging groups because they could not rely on the buffering effect provided by rivers and lakes and their associated resources. After a brief description of settlement system, resource management, technology and social organization used by local people we then discuss the strategies that appear to have been crucial for them to respond to both strong seasonal variation and continental to global climate changes during five millennia. We conclude that to keep the responsiveness the local hunter-gatherers have consistently chosen the path of greater flexibility and opportunistic technologies at the cost of a small degree of specialisation and keeping groups small. Paradoxically, high degree of resilience of local hunter-gatherers has led to a low rate of change in most archaeological indicators of cultural evolution.

2 IN TUNE WITH NATURE? RESOURCE MANAGEMENT DURING LATE PLEISTOCENE AND EARLY HOLOCENE IN THE WESTERN FAÇADE OF IBERIA

Gameiro, Cristina (UNIARQ -FLUL, Universidade de Lisboa)

Climate change during Pleistocene-Holocene transition altered the environment and human populations had to adapt their foraging strategies.

Deglaciation resulted in sea-level rising, leading to an expansion of flooded areas. This, along with the expansion of woodlands, favoured coastal circulation, as can be inferred from site location. Subsistence strategies started to change during the tardiglacial period: there is a reduction in the representation of species within faunal assemblages and an increase of fish, birds, and small mammals (particularly rabbits), although deer and wild boar still predominate in early Holocene faunal assemblages.

These environmental shifts were accompanied by cultural changes. The preferential use of local raw materials indicates a contraction in the geographic areas explored. During this transitional period tool assemblages are characterized by miniaturization, a diversity of microlith types and a trend towards regionalism.

By analyzing site locations, subsistence strategies, raw material use and technological choices, this paper aims to elucidate how late Pleistocene and early Holocene communities of the Western façade of Iberia adapted their resource management practices to cope with these changing conditions. Furthermore, the relevance of these examples in promoting discussions on modern sustainability and adaptability will be explored.

3 MAGDALENIAN ALPINE IBEX HUNTERS IN THE HIGH MOUNTAINS

Valde-Nowak, Pawel (Jagiellonian University) - Kowal, Magda (Jagiellonian University) - Kraszewska, Anna (Jagiellonian University) - Kościuk-Zatupka, Julia (Jagiellonian University) - Nadachowski, Adam (Polish Academy of Science) - Sojak, Marian (Slovak Academy of Science) - Skłucki, Jakub (Jagiellonian University) - Wacnik, Agnieszka (Polish Academy of Science) - Kerneder-Gubała, Katarzyna (Polish Academy of Science)

Recently, excavations have revealed traces of a Late Paleolithic site in the high mountain landscape of the Tatra Mountains in Slovakia. The remains of a hearth, several hundred stone and bone artifacts, and the remains of hunted animals have been preserved in the Hučiva cave. Among them, many bones of the Alpine ibex are preserved, which is absent from these mountains region today. Accelerator Mass Spectrometry (AMS) dates point to the Bölling interstadial, and the tool inventory is dominated by forms such as shouldered points and other examples well-known from Western Magdalenian sites. The site itself is located in a cave near the upper edge of the forest, and below the front of the local glacier.

The presentation would focus mostly on the already derived results from the ongoing excavations, as well as shortly discuss the proposed further points and open questions, those need to be clarified during next seasons.

4 FOUR THOUSAND YEARS OF CLIMATIC VARIATION, FLEXIBILITY, AND RESILIENCE AMONG HOLOCENE HUNTER-FISHER-GATHERERS ALONG THE SUDANESE NILE

Varadinová, Lenka (Charles University, Faculty of Arts) - Varadin, Ladislav (Institute of Archaeology of the CAS, Prague; Charles University, Faculty of Arts) - Ambrose, Stanley (Department of Anthropology, University of Illinois, Urbana, IL, USA)

The Sahel region has among the highest inter-seasonal climatic variation in the world. It is characterized by a long dry season, with monsoon rains between May and September bringing sudden but comparatively short-term increases in biomass, including food resources. Local populations are adapted to this variation through their reliance on food-production, storage, and markets. However, droughts in the Sahel during the 1970s–1980s show the devastating impacts of short-term changes of the inter-seasonal variation on demography, political stability, and security, and the limits to adaptability in the Sahel. While more favourable climate prevailed in the Sahel during the African Humid Period (ca. 14.7–5.5 ka), inter-seasonal and inter-annual variation in climate likely constituted a major factor influencing the way of life in this region during that time. For the foraging communities along the Nile, the challenges the variation brought were in part balanced by the river, which constituted a stable source of water and diverse food resources, especially during the dry seasons. However, the Nile River is also characterized by intra- and inter-annual variations whose magnitude depends on climate in its headwaters. In this paper, we present the evidence from the Sabaloka Mountains on the central Sudanese Nile where Mesolithic hunter-fisher-gatherers managed to negotiate seasonal and inter-annual variations in rainfall and river levels and sustain continual settlement in this region for four thousand years. Their diverse settlement, subsistence, technological, and social strategies from the first postglacial reoccupation of central Sudan ca. 10.7 ka until the first arrival of food-production ca. 7 ka attest to both long-term flexibility and resilience not only in the face of the inter-seasonal variation and its changes, but also in the face of global climatic events.

997 CHAÎNE OPÉRATOIRE AND LIFE CYCLE OF PROTOHISTORIC AND ANCIENT BUILDING MATERIALS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Péfau, Pierre (École française de Rome) - Ducret, Pauline (École française de Rome) - Dessales, Hélène (École normale supérieure - Université PSL; Université de Lausanne) - Pizzo, Antonio (Scuola Spagnola di Storia e Archeologia di Roma)

Session format: Regular session

The aim of this session is to explore a key theme in research about architecture in ancient societies, that has been renewed since the end of the twentieth century: the chaîne opératoire and life cycle of building materials. Protohistoric and Ancient architecture has long been studied from a morphological point of view (floor plans, organisation of interior space, topographical insertion) or through construction techniques (typology of materials used to build the different parts of a construction: foundations, elevations, roofing...). The development of construction archaeology and the new technologies on which its methods are based have made it possible, in recent decades, to consider materials not just as elements of the construction techniques, but as objects of study for themselves. This allows researchers to document previously invisible aspects that were essential to have a detailed understanding of architectural practices: the economics of construction, site management and craft skills, the supply, transport, storage and trading of resources, maintenance, reuse and recycling.

We would like to bring together didactic contributions in order to create a synthesis organised by materials and comprising two complementary aspects: on the one hand, contributions presenting a material's chaîne opératoire, from its extraction/production to its primary and secondary use; and on the other hand, contributions proposing new methods for studying a material. The main building materials can be considered: stone (limestone, travertine, tuff, marble...), terracotta (bricks, tiles, technical elements) and raw earth (mud bricks, cob, rammed earth, wattle and daub), timber, plants (reeds, straw...), mortar, metals, glass.

The expected outcome is an overview of the technical processes and economics of construction in Europe for more than a millennium (8th c. BC - 5th c. AD). It could be an initial meeting to encourage the creation of a working group on building materials in order to share methods and results.

ABSTRACTS

1 'HOC OPUS BONUM SUO CUIQUE FACITO': WHAT THE ANCIENT TEXTS TELL US ABOUT THE LIFE CYCLE OF BUILDING MATERIALS

Pauline, Ducret (École française de Rome)

The notion of a "chaîne opératoire" is a modern one, applied to ancient monuments by the archeologists specialized in ancient construction. It is therefore an anachronism that allows today's researchers to take account of ancient realities.

Yet ancient texts on the subject, written in Greek or Latin, do exist. From Greek inscriptions to the Law of Pozzuoli, from Cicero's letters to Vitruvius' *De Architectura*, from Strabo to the Justinian Digest, texts, or rather fragments of texts, deal with the many operations involved in supply of materials: the selection of materials, the choice of extraction sites, the organisation of transport, the various stages of material processing, as well as storage, dismantling, reuse practices, the provision and maintenance of tools, etc. The texts are as diverse as they are rich on the subject and, although they do not offer a complete chaîne opératoire, they enable us to tackle virtually every stage in the life cycle of building materials.

These texts also help us to understand how the Ancients conceived the life cycles of materials. We will therefore try to determine which stages were considered to be complementary or were carried out by the same players, which were, on the contrary, decoupled from each other, where were the divisions and ruptures in the process, and whether they overlap with our contemporary conceptions.

2 VOLCANIC TUFF AND OTHER SOFT STONES IN ANCIENT CONSTRUCTION

Diffendale, Daniel (Scuola Superiore Meridionale)

While there are many different types of tuff, varying from volcano to volcano and eruption to eruption, shared geological characteristics give rise to similar physical characteristics relevant to the process of working the stone and its potential uses in construction—similar affordances—making it a useful analytical category to consider as a whole. From the point of view of stonecutters, calcareous tufa can also be considered along similar lines (indeed, the shared etymology is one index of this similarity), within a broader category of soft stones (the lapides molles of Vitruvius or the pietra dolce of later Italian stonecutters). Soft stones require less time, less labor, and less iron to extract and shape, and their lower densities make them easier to transport; they can thus be conceptualized as a midpoint between wooden and earthen architectures and those in harder stones, such as hard limestones and marbles. (Likewise, the relative quickness of their working can often be matched conceptually by the quickness of their erosion if left exposed to the elements.)

Developments in volcanology in recent decades have made it possible to study the quarry provenience of tuff used in ancient architecture, which allows for a better understanding of the beginning points of the chaîne opératoire; brief case studies from Rome will serve as examples.

Many of the other steps in the process must be read from the materials themselves (the softness of the stone and its aversion to polishing can allow for better preservation of toolmarks), or the quarries from which they were extracted, or inferred via more recent ethnographic parallels, such as the evidence for extraction of tuff around Naples in the early part of the 20th century.

3 FROM QUARRIES TO BUILDINGS: EXTRACTION, MANUFACTURING, TRANSPORT AND USE OF THE AURISINA LIMESTONE IN THE ROMAN AGE

Previato, Caterina (Università di Padova) - Giroto, Chiara (Università di Padova) - Dilaria, Simone (Università di Padova) - Bridi, Eliana (Università di Padova) - Bonetto, Jacopo (Università di Padova)

The exploitation of stone resources for building purposes played a fundamental role in the economics of the Roman Empire as well as their availability and features strongly influenced the shaping of ancient architecture. Generally, stone materials were selected on the basis of their quality and ease of procurement. In fact, it has been shown that in Roman times cities generally sourced stone from quarries situated at a distance no more than 20–30 km. In this general scenario, there are, however, some exceptions. This is the case, for example, of the Aurisina limestone, a stone quarried in North-Eastern Italy, not far from the cities of Aquileia and Trieste, which was not only used locally but also traded on a regional and extra-regional scale, being extremely appreciated for its aesthetic and physical-mechanical characteristics.

The present work aims at analyzing the entire process of extraction, manufacturing, transport and use of the Aurisina limestone in the Roman age. Through a multidisciplinary approach, incorporating archaeological data and archaeometrical analysis, this study explores the extraction dynamics employed in the Aurisina quarries, the craft skills

involved in shaping limestone into architectural elements, and the logistical challenges faced in transporting these materials across vast distances to construction sites.

A specific focus will be placed on the analysis of the type of artefacts produced, in order to reconstruct on the one hand the techniques and tools used to carve the Aurisina stone, and on the other to shed new light on the location (in the quarries? in the cities?) and organization of the stone workshops.

By investigating the different steps of the production process of Aurisina limestone, this research provides valuable insights into the exploitation and management strategies of stone resources in Roman times.

4 FROM QUARRY TO DECOR : AN EXPLORATION OF THE MARBLE PRODUCTION CHAIN IN ANTIQUITY

Barataud, Laura (Ausonius)

As a symbol of political and social prestige, marble was a key material in Roman architecture and ornamentation. The chain of operations for this raw material is a complex process that reflects the technical competence of marble craftsmen, from quarrying to the installation of decorations on building sites. Observing the traces left behind during the various phases of work also offers essential clues to a better understanding of decorative systems such as marble veneers, which are often found in fragmentary condition. Tracing the various stages involved in setting up the ornament, as well as the various elements inherent in its installation, reveals the technological imperatives with which ancient craftsmen may have been confronted. Their expertise in selecting materials, the understanding of marble's physical properties, as well as the solutions they found for maintaining veneers, demonstrate the high level of technical know-how involved and the extent of their thinking on the installation of marble decorations.

5 A THOUSAND YEARS, A THOUSAND RECIPES: THE CHAÎNE OPÉRATOIRE OF ANCIENT LIME MORTAR, BETWEEN KNOW-HOW AND USES

Coutelas, Arnaud (UMR 8546 AOROC (France))

Ancient lime mortar, or rather the famous "Roman concrete", has a truly legendary image. Ever since medieval times, people have praised the quality of these materials. Indeed, some of them are truly admirable, to such an extent that they are used as analogues for some of today's cements in order to analyse their degradation over time. But Roman production is not limited to these few remarkable concretes, prepared with lime and pozzolans. While these very special volcanic ashes may have travelled around the Mediterranean Sea, particularly from the Phlegraean Fields, for the main part the raw materials were always local and the nature of lime mortars therefore appears to have depended on the nearby geological environment, as well as on a form of local appropriation, which, on the scale of the Empire, offers us great diversity. This diversity also depends to a large extent on how the material is used in architecture. In fact, the recipe for mortar or concrete is not the same depending on whether it is used as a construction mortar, a decorative plaster or a technical element.

Even if this remains to be clarified, we now know that the whole range of Roman techniques emerged over time, originally through successive contacts with the Greek and Punic worlds, before developing in their own right. The know-how did not disappear after the fall of the Empire, but migrated to the East in conservatories such as the Byzantine world, where it evolved. In the West, oblivion was only relative, and there were even innovations in the chaîne opératoire, such as mechanical mortar mixers, an invention probably dating from the 7th century.

6 THE EXPLOITATION OF VOLCANIC POZZOLANS IN THE ROMAN WORLD. THE CURRENT STATE OF ART IN LIGHT OF RECENT DISCOVERIES

Dilaria, Simone (Department of Cultural Heritage, University of Padova; Inter-Departmental Research Centre for the Study of Cement Materials and Hydraulic Binders, University of Padova) - Secco, Michele (Department of Cultural Heritage, University of Padova; Inter-Departmental Research Centre for the Study of Cement Materials and Hydraulic Binders, University of Padova) - Bonetto, Jacopo (Department of Cultural Heritage, University of Padova) - Previato, Caterina (Department of Cultural Heritage, University of Padova)

The use of volcanic pozzolans to improve the hydraulic properties and cohesive capabilities of aerial lime-based mortars represents one of the most brilliant achievements of antiquity. Several Latin authors, such as Vitruvius and Pliny, celebrated the outstanding properties of the pulvis puteolanus. This is a peculiar volcanic ash, outcropping around the Gulf of Naples, that was particularly recommended for improving the durability of concretes in underwater conditions. Recent research indicates the rapid spread of Neapolitan pozzolans in Roman territories around the Mediterranean from the Augustan Age onward and this product monopolized markets due to its excellence in crafting long-lasting hydraulic mortars and concretes. The reasons for this massive commercialization probably lie in trade logistics: the outcrops are located close to the coast of the Bay of Naples, where some of the most important harbors of the Roman World, such as Puteoli, Baia and Miseno, were located.

Despite the prominence of Vitruvian pulvis, other effective pyroclastic products for ancient mortars were exploited in ancient times in the Provinces. Ongoing research reveals increased interest in the exploitation of "alternative" volcanic pozzolans across the Roman Empire, fostering developments in the geochemistry and materials science of ancient construction materials.

This contribution offers a concise overview of the current state of research on this topic. New evidence from various Italian sites, including Nora and Sant'Antioco in Sardinia, Aquileia in Friuli Venezia Giulia, Padova and Montegrotto in Veneto, and Lio Piccolo in the Lagoon of Venice, currently investigated at the Department of Cultural Heritage of the University of Padova, are shedding new light on the utilization of both "Vitruvian" and "alternative" volcanic pozzolans in ancient constructions. These findings provide intriguing insights into the deep technological understanding of ancient craftsmanship regarding local land resources and their optimal utilization for the production of robust and long-lasting concrete-based structures.

7 FROM FOREST TO BUILDING: CHAÎNE OPÉRATOIRE AND LIFE CYCLE OF TIMBER IN ANCIENT ROMAN WESTERN EUROPE

Péfau, Pierre (Ecole française de Rome)

Timber is rarely preserved on archaeological sites and can generally only be identified as imprints or holes. Because of these conservation difficulties and research traditions focused on stone and brick construction, timber is usually under-represented in Roman architectural studies. Recent excavations in wet contexts - particularly in urban areas - have revealed the importance of this material in ancient architecture. Moreover, timber is a first-rate environmental and technical marker that records its entire chaîne opératoire, from forest to building.

The study of wood anatomical features is essential for taxonomic identification and for understanding species selection. Dendrochronological and dendroprovenancing studies make it possible to date the tree's felling and to determine the geographical origin of a timber piece. Although it is generally considered an easily accessible material, timber was often imported over several hundred kilometres because of the forest decline in many European areas. Dendro-typological analyses provide valuable information on forest condition and management method, which influenced the architectural forms and tools used. Technological (shaping and slashing processes) and traceological approaches (toolmarks and carpenters' marks identification) are fundamental to understand woodworking methods and the timber framing achievement. As a precious resource, the beam lifespan often extends beyond its first use. Combining different methods will enable us to examine different cases of reuse and recycling.

The aim of this paper is to provide an overview of the various stages in the timber chaîne opératoire, while highlighting the different methods of studying timber. This synthesis is based on results of recent excavations carried out in Italy, France, Switzerland and United Kingdom, mainly in urban settlements dating from the 1st to 5th centuries AD. Ancient texts and ethnoarchaeological data will also be consulted within a critical comparative approach.

8 A PROPOSITION OF CHAÎNE OPÉRATOIRE FOR THE WOODEN ELEMENTS OF THE PARAPET WALK OF THE HEUNEBURG FORTIFICATION AROUND 600 BC

Remise, François (Independent researcher)

Around 600 BC, the community of the Heuneburg (southwestern Germany) built a fortification around the upper and the lower towns. The fortification of the upper town consisted in a mudbrick wall on a stone basement surmounted by a wooden parapet walk, replacing a more traditional fortification made of wooden boxes filled with earth. This 775 metres long parapet walk consisted in a timber structure of oak beams with a roof made of wood shingles. In this paper, I propose a chaîne opératoire of the wooden elements of this parapet walk, from felling trees to installing the wooden parts on the wall, including all transport and manufacturing phases of the various wooden components. An estimation of the costs related to all the phases of the supply, manufacturing and installing processes is then proposed, using the Architectural Energetics method with a choice of labour rates made after having considered the specialized literature and having taken advice from experts.

9 THE REALITY OF ANCHORING JOIST FOR WOODEN FLOORS AT OSTIA: INSIGHTS FROM TRACES IN THE WALL

Yoshimura, Yuji (Kyushu University) - Hori, Yoshiki (Kyushu University (Professor))

This study based on detailed 3D laser scanning to measure the wall sockets remained in Ostia. Although wooden joists had been now lost, methods of anchoring joist to wall have been reconstructed and divided into 6 groups by Ulrich.

From the data obtained, it is at least possible to reconstruct in detail the appearance of the remaining socket holes in the wall. Socket holes generally have one or two of the four corners missing from the square, a feature observed in many holes, and may represent the shape of the log ends.

When wood is generally used in structures, for aesthetic and practical reasons, the process of squaring is used to shape the timber into long blocks with a square or rectangular outside shape. Squaring is primarily done using axes (squaring axe, broad axe) and pit-saws. Particularly, to cut straight without being hindered by the grain of the wood, a tool called a framed pit-saw, with a blade fixed in the center of a wooden frame, was used.

Considering the shape of the socket holes observed in the ostia, it can be speculated that squaring resulted in a shape resembling the rounded end of a log at the corners. By using pit-saws to divide the section into two or four parts, it can be understood that the width and height of the beams were adjusted. In this technique, the initial squaring process may have been performed using simpler axes.

Meiggs mentions that in large residential developments like 2nd century Ostia, the use of wood changed from sturdy hardwoods to more easily worked softwoods such as fir and pine. Similarly, considering the cross-section of wood seen in socket holes, squaring may have been done practically to produce larger cross-section materials.

10 PERISHABLE, DEPRECIATED BUT AFFORDABLE: PLANT FIBRES AND THEIR « CHAÎNE OPÉRATOIRE » IN GREEK AND ROMAN CONSTRUCTIONS

Azzi, Clothilde (CRHEC - Université Paris-Est Créteil; AOrOc - ENS-PSL)

Although very common in Greek and Roman constructions, the use of plant fibres such as wheat and rye straw, reed, bulrush, hemp and wicker remains largely understudied. This general lack of interest can be explained by the scarcity of plant remains found through archaeological research, due to their perishable nature. Indeed their limited durability makes it difficult to reconstruct their "chaîne opératoire" - the waste produced during the processing of the stems disappears quickly after cutting and what remains from the finished product is often reduced to its imprint in other, more durable materials. The written sources are also disappointing from a technical point of view, as Greek and Roman authors did not bother to detail the processes involved in using these unpretentious materials, which were considered to be the preserve of the poor. It is also important to mention the particularities of the supplying and working process of plant fibres, the stages of which do not always follow a strictly defined sequence. As they are readily available in the surrounding environment and require minimal processing before use, plant materials have often been used in self-building constructions. For this reason, in the absence of clearly defined workers and professional networks, the question of the plant fibres' « chaîne opératoire » has long been ignored by researchers. However, combining the analysis of xyl-, anthrac- and palynological remains with data from textual and ethnographic sources, makes it possible to reconstruct the different phases of this « chaîne opératoire », which is more complex than it first appears. The entire life cycle of plant fibres can therefore be tracked down, from culture to harvest, transport to storage, application to maintenance.

11 METAL IN ROMAN CONSTRUCTION: EXAMPLES OF USE AND PRODUCTION STRUCTURES

Loiseau, Christophe (UMR 8546 (ENS-AOROC) - EVEHA)

In Roman construction, metal objects (iron, bronze, lead) have been very little studied, often due to salvage operations that have deprived us of a large part of the documentation. Yet ancient metals played a key role in fixing architectural elements, providing decorative supports, equipping and embellishing buildings, and sometimes even restoring them after damage. This presentation will illustrate the diversity and ingenuity of metal elements used in Roman construction. The presentation will focus on a number of specific examples. Metal parts in a variety of shapes were used in the construction of ceilings. The systems developed were adapted to the spaces built (galleries, thermal baths) and to the expected forms of construction (vaults, flat ceilings). Fixing brackets for marble decorations provide information on the craftsmen's skills and construction stages. The management and heating of water also suggest a variety of equipment, such as boilers and taps, in addition to pipe networks whose originality is not always fully appreciated. In some cases, builders set up temporary workshops on site to adjust and install these metal parts. These structures, which we'll also take a closer look at in a few examples, also inform us about the craftsmen's know-how and the relationships they maintained with the other trades present on site.

12 SUPPLY AND TRANSPORTATION OF BUILDING MATERIALS IN OSTIA ANTICA: THE "ISOLATO DELLE TRIFORE" AS A CASE STUDY

Vyverman, Sarah (École Normale Supérieure de Paris; UCLouvain; F.R.S.-FNRS)

While the topic of supply and transportation of building materials has been discussed extensively for the city of Rome, this research issue has thus far not been addressed properly for the city's main harbour, Ostia antica. This presentation aims to fill this research gap by focusing on the construction site of a particular city block: the "Isolato delle Trifore", located in the third region of Ostia antica. This urban block consists of two buildings that have been dated to the 2nd century AD, which were built on previous structures dating back to the end of the 1st century BC. In this talk, I will, firstly, analyse the different types of building materials of these structures, along with those belonging to the earlier phases of the Isolato delle Trifore of which we have traces in the archives. These building materials will be

examined through a method developed by Gilles Fronteau (University of Reims Champagne-Ardenne) that enables for classifying these materials according to the distance between their extraction/production site and their place of use. Thus, the building materials of the Isolato delle Trifore will be subdivided into different areas of supply, based on their proximity to the site: immediate, adjoining, local, regional, and extra-regional. Secondly, I will assess the manifold strategies of transportation of these building materials by land and/or river, from their original location to Ostia antica. By examining the process of supply and transport of building materials to one city block in Ostia antica, this paper aims to gain a better understanding of the practical organisation of construction in the urban landscape more widely, thus addressing significant issues related to the supply and transportation chain of building materials to and within Rome's main harbour.

13 FROM EARTH TO EARTH. CHAÎNES OPÉRATOIRES AND ECONOMY OF RAW EARTH : THE ABSOLUTE MATERIAL ?

Leal, Emilie (INRAP - National Institute for Preventive Archaeological Research; UMR 5140 Archéologie des Sociétés Méditerranéennes)

Among all the materials used in architecture, raw earth is the only one with absolute reversibility properties. This character, now recognized as an undeniable asset in terms of engineering and ecology, represents an ongoing challenge in terms of identification and understanding in archaeological contexts. So, while the technical definition of cob, mud bicks, rammed earth or wattle and daub has been the focus of a great deal of attention over the last twenty years, and analysis protocols have been greatly enhanced thanks to an interdisciplinary approach, archaeological examples regularly reveal the extent to which these different construction techniques are adapted, adaptable and go beyond their original limits. The concept of chaîne opératoire, still too rarely applied to this material, enables us to clarify its overall system and its implications (particularly economic, constructive, taphonomic and topographical), and also to understand its status alongside other materials. In this presentation, we address the question of raw earth in the light of this concept. We present the different techniques involved, and then take a closer look at the issue of supply, technical variations and the recycling processes highlighted in archaeological contexts, based on specific examples.

14 HEARTH OR PLASTER? A METHODOLOGICAL PROPOSAL TO INTERPRET FLAT SURFACE EARTHEN REMAINS FROM MEDITERRANEAN PROTOHISTORIC SECONDARY CONTEXTS

Belarte, Maria Carme (ICREA (Catalan Institution for Research and Advanced Studies); ICAC (Catalan Institute of Classical Archaeology)) - Mateu, Marta (ICAC (Catalan Institute of Classical Archaeology)) - Pastor Quiles, María (Universitat d'Alacant; ICAC (Catalan Institute of Classical Archaeology)) - Saorin, Carme (GRAP (Grup de Recerca en Arqueologia Protohistòrica), Institut d'Arqueologia de la Universitat de Barcelona (IAUB)) - López Reyes, Dani (ArqueoVitis, SCCL) - Canela-Gràcia, Joan (ICAC (Catalan Institute of Classical Archaeology)) - Corrales, Antoni (ICAC (Catalan Institute of Classical Archaeology)) - Prats, Georgina (Universitat de Lleida) - Anguera, Maria (ICAC (Catalan Institute of Classical Archaeology))

This paper addresses the methodological and interpretative challenge of studying fragments of constructions recovered out of context at protohistoric sites, often as part of the fill of pits. These often include a series of elements with a flattened surface, that, from a preliminary macroscopic observation, could be interchangeably interpreted as belonging to combustion structures or as earthen plasters, or even as other architectural remains.

Even though earth-building materials are being increasingly studied, the ones coming from secondary contexts are rarely the object of research, and so are the remains of combustion surfaces built with earth.

Applying an interdisciplinary methodology for the study of these materials increases the information about the construction processes. Also, about the use of the structures behind these materials. More precisely, we propose thin-section micromorphology and FTIR analyses, to identify the intervention of an intentional combustion process and distinguish surfaces of fire installations from other construction parts.

This research addresses earthen materials coming from the sites of Turó de la Font de la Canya, Mas Cap de Ferro and El Vilar de Valls (Catalonia).

15 LONG LIFE FOR AN EXCEPTIONAL BUILDING MATERIAL: FIRED BRICK AND TILE

Bukowiecki, Evelyne (École française de Rome) - Dessales, Hélène (École Normale Supérieure - Université PSL)

Fired bricks and tiles are emblematic building materials of Roman architecture, but have much older cultural origins. Wherever clay is found, these materials continue to play an essential role throughout the history of architecture, from the 6th century B.C. to the present day, both as new and recycled materials.

This article begins by drawing on examples from Rome and Pompeii to outline the key stages in the chaîne opératoire and life cycle of ceramic building materials: extraction and preparation of clay, shaping of elements, drying and possible stamping, firing, primary storage at production sites, transport, secondary storage in the city, transport to

building sites, storage on building sites, implementation and, possibly, organization of deconstruction sites, recovery and storage of materials for recycling, selection, transformation, redistribution and re-use of materials by other building processes.

In the case of Rome, we now have a good understanding of the entire brick chaîne opératoire, but less so for roof tiles. In the case of Pompeii, we can detect local specificities in the chaîne opératoire for flat tiles, re-cut for use in masonry.

The aim is then to position the chaîne opératoire of baked brick and roof tile within the chaîne opératoire of the other materials presented in this same session of the congress and, while identifying common points, to specify their technical, geographical and cultural specificities. This part of the contribution will draw on the many case studies presented at recent international conferences held in Italy on Roman brick, on the use of brick in imperial building sites in 2014 (“convegno Laterizio I”), on the birth of architectural terracotta in 2016 (“convegno Laterizio II”) and, finally, on the reuse and heredity of architectural terracotta in 2019 (“convegno Laterizio III”).

16 THE BRICK CONSTRUCTION INDUSTRY IN IMPERIAL ROME: WORKING PROCEDURES AND QUANTITATIVE ANALYSES

Camporeale, Stefano (Università di Siena) - Serlorenzi, Mirella (Soprintendenza Speciale Archeologia Belle Arti Paesaggio di Roma)

The contribution proposes a method for the quantitative study of masonry based on the dismantling of a number of structures from the Imperial age (brick-faced concrete) found in Piazza Dante in Rome and on a comparison with the substructures of the Domus Tiberiana, one of the imperial palaces on the Palatine Hill. The analysis is also set up according to an anthropological approach, careful to highlight the sequence of workings adopted for each type of brick. With regard to the context of Piazza Dante, some preliminary data were presented at the 2016 conference ‘Costi, tempi e metri cubi’ in Padua (published in 2017) and at the Third International ‘Laterizio’ Conference in Rome in 2019 (unpublished poster). Now the analysis has been completed on all the dismantled masonry, belonging to different chronological periods, and built using different techniques with both newly produced and salvaged materials.

All the elements that made up the masonry (core and facing) have been counted: the building process of these structures will be hypothesized, together with the time and labour needed for construction. New observations on the cutting and working procedures of the bricks will also be presented, focusing on the most attested types: bessales and roof tiles of a special format, which we can define ‘piccole tegole’ (small tegulae) on the basis of some previous studies (Steinby, Delaine, Camporeale). These observations will be compared with data coming from the study of other contexts in Rome, especially the Domus Tiberiana, of which a detailed stratigraphic reading of the substructures is available, especially in relation to the Hadrianic period, and Ostia.

1000 ADVANCED METHODOLOGIES FOR LIFE HISTORY RECONSTRUCTION IN BIOARCHAEOLOGY

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy) - Esposito, Carmen (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Madgwick, Richard (School of History, Archaeology and Religion, Cardiff University, Cardiff, UK) - Lugli, Federico (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany) - Buckley, Michael (Manchester Institute of Biotechnology, University of Manchester, Manchester, UK)

Session format: Regular session

The growing use of advanced scientific techniques has been revolutionising the study of the past, offering nuanced interpretations that were previously unimaginable. Advanced analyses of human and faunal remains from archaeological or palaeontological horizons are nowadays a constant presence in bioarchaeological studies, providing a detailed reconstruction of individual life histories and biocultural adaptation strategies.

High-spatial resolution multi-isotope (such as $^{87}\text{Sr}/^{86}\text{Sr}$, $\delta^{15}\text{N}$, $\delta^{13}\text{C}$, $\delta^{34}\text{S}$, $\delta^{18}\text{O}$) and multi-element (Sr, Ba, Zn, Mg, U, REE, etc.) analyses of human and faunal teeth and bones have become ever more common. Coupled with dental histomorphometry, palaeoproteomics and isoscapes, these methods have refined our understanding of people and animal diets, mobility, and nursing in the past, also allowing the quantification of the impact of diagenesis on the mineralized tissues. Furthermore, the use of laser-ablation mass spectrometry (LA-(MC)-ICP-MS) and multi-isotope analysis for detecting seasonal human and livestock mobility provides spatial-temporal patterns of behaviour with very high precision. These cutting-edge techniques interwoven with the archaeological record have dramatically improved our knowledge of the past. Nonetheless, our awareness of possible pitfalls within these methods is increasing. The proposed session offers the occasion to show diverse types of multidisciplinary projects, discussing outcomes and drawbacks, arising possible aspects that can be improved in the field. We welcome papers that provide the ap-

plication of the previously mentioned advanced techniques in bioarchaeological studies from different archaeological areas and periods and particularly encourage papers that demonstrate the potential of maximising multi-factorial data even from a single sample.

ABSTRACTS

1 SEA SPRAY EFFECT ON ^{14}C DATING AND BEYOND: ^{13}C AND ^{14}C ANALYSIS SHEDS LIGHT ON SEA SPRAY INDUCED PHYSIOLOGICAL REACTIONS

Göhring, Andrea (Christian Albrecht University Kiel; GEOMAR Helmholtz Centre for Ocean Research Kiel) - Hüls, C. Matthias (Leibniz Laboratory for Radiometric Dating and Stable Isotope Research Kiel) - Mayr, Christoph (Friedrich-Alexander-Universität Erlangen-Nuremberg; Ludwig-Maximilian-Universität Munich) - Hamann, Christian (Leibniz Laboratory for Radiometric Dating and Stable Isotope Research Kiel)

The transfer of marine aerosols to terrestrial environments via sea spray influences the stable isotope signature (e.g. $\delta^{13}\text{C}$) of coastal environments, including plants, animals, and humans. Although prior research has explored the influence of sea spray on the stable isotope fingerprint of coastal specimens, a notable knowledge gap exists regarding its effect on radiocarbon dating in terrestrial organisms within coastal regions. Beyond direct effects, the sea spray induces physiological reactions, particularly salinity stress-related responses. While the marine reservoir effect is known to affect the ^{14}C signal of terrestrial consumers of marine food, the sea spray affects the isotope signature of individuals consuming terrestrial food.

This study investigates the influence of sea spray on the ^{14}C concentration in plant tissues through an artificial sea spray experiment conducted in a greenhouse. Beach grass was sprayed with mineral salt solutions with only traces of NaCl or brackish water from the Schlei inlet or the Baltic Sea. These plants should exhibit a ^{14}C signal closely aligned with the contemporary atmospheric $^{14}\text{CO}_2$ composition. However, three treatment groups displayed distinct deviations in radiocarbon concentration.

Plants sprayed with Schlei water, Baltic Sea water, or a mineral salt solution with elevated bicarbonate concentration were depleted in ^{14}C compared to the atmosphere. The absorption of substantial amounts of ^{14}C (about 56-68%) from dissolved inorganic carbon (DIC) in spray water seem to partially mask the (opposed) effects of plant physiological responses to salinity or bicarbonate stress on ^{14}C , while these responses result in reduced discrimination against ^{13}C .

The results emphasize the necessity of a comprehensive understanding of these interactions, shedding light on the direct and indirect sea spray effect on the carbon isotope composition of both modern and archaeological plant and faunal tissues in coastal environments.

2 SR ISOTOPES SPATIAL DISTRIBUTION IN ITALY: GEOCOMPUTATIONAL TOOLS TO TRACK THE GEOGRAPHICAL ORIGIN OF HUMANS AND ANIMALS

Lugli, Federico (Institute of Geosciences, Goethe University Frankfurt) - Müller, Wolfgang (Institute of Geosciences, Goethe University Frankfurt) - Cipriani, Anna (Department of Chemical and Geological Science, University of Modena and Reggio Emilia)

Reconstructing the geographical origin, the provenance and the movements of humans and animals is key in many fields of study, including ecology, archaeology and forensic anthropology/medicine. To this end, strontium isotope tracers have historically played a central role due to their link with the lithological and geological features of the landscape. Yet, to accurately interpret provenance through isotope systematics, it is paramount to have reference datasets of geobiological/environmental samples from the area of interest as comparison. Such data can be spatially modelled through canonical geostatistical and machine learning techniques, to obtain continuous maps of isotope distribution, i.e. isoscapes. In addition, these maps can be ‘queried’ e.g. by Bayesian methods to obtain estimated probability of geographical origin and possibly overcome ‘eyeball’ approaches. Here, we present the current state of the Italian Sr isoscape and novel freely available online-tools that can be used to test the geographical origin of biological samples. Specifically, we will show flaws and merits of traditional interpolation methods (e.g. Kriging), compared with novel automated learning algorithms such as (Spatial) Random Forest, and we will demonstrate how sample provenance can be defined numerically by combining isoscapes, related spatial uncertainties and Bayesian inversion methods. Overall, these approaches can strengthen our interpretation of human and animal provenance and mobility, within a robust statistical framework.

3 TRACING MOBILITY: EXPLORING ISOSCAPES AND STATISTICAL METHODS IN ASSESSING ALLOCHTHONY OF PAST POPULATIONS

Stuart, Emma (Sapienza University of Rome, Rome, Italy) - Esposito, Carmen (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Bondioli, Luca (Department of Cultural Heritage, University of Padua, Italy; Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy) - Di Renzoni, Andrea (CNR-ISPC (Consiglio Nazionale delle Ricerche – Istituto di Scienze del Patrimonio Culturale)) - Lugli, Federico (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany) - Vanzetti, Alessandro (Sapienza University of Rome, Rome, Italy)

Strontium isotope analyses ($87\text{Sr}/86\text{Sr}$) have increasingly gained prominence in reconstructing past human mobility. For this purpose, anthropological samples are typically compared to various kinds of samples pertaining to areas varying in proximity to the site of provenance, forming a local baseline, which reflects the isotopic fingerprint of a specific area. Although many Italian studies have traditionally utilised this approach, isotopic maps, namely isoscapes, are now being widely employed.

Isoscapes cover entire regions and can be based on bioavailable or non-bioavailable materials, depending on the research objectives. The bioavailable isotope is often favoured in archaeological research, as it is deemed more representative of the isotopic fingerprint of living beings. The reliability of isoscapes depends on the samples used and the statistical methods employed, including ordinary kriging, universal kriging and machine learning techniques.

Several isoscapes have been developed for the Italian territory, using various geostatistical and theoretical approaches. This research aims to create and evaluate an updated version of the Italian isotope, while in parallel re-elaborating and comparing data by using different geo-statistical and statistical methodologies. We therefore propose an analysis of a number of prehistoric and protohistoric case studies (taken from existing literature), where ranges of values are delineated around the burial site, based on distances calculated in walking hours, known as isochrones, representing varying degrees of mobility from the site in question. The results are then statistically processed in order to understand the degree of autochthony of individuals, aiming to transcend the rigid local versus non-local dichotomy that sometimes characterises isotopic analyses.

4 NOTHING GOES TO WASTE: A NOVEL PROTOCOL TO OPTIMIZE DESTRUCTIVE SAMPLING OF ANCIENT TEETH

Esposito, Carmen (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Galbusera, Alessia (Department of Cultural Heritage, University of Padua, Padua, Italy; Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy) - Gigante, Melania (Department of Cultural Heritage, University of Padua, Padua, Italy) - Higgins, Owen (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy; Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Lugli, Federico (Institute of Geosciences, Goethe University Frankfurt, Frankfurt Am Main, Germany; Frankfurt Isotope and Element Research Center (FIERCE), Goethe University Frankfurt, Frankfurt am Main, Germany; Department of Chemical and Geological Science, University of Modena and Reggio Emilia, Modena, Italy) - Müller, Wolfgang (Institute of Geosciences, Goethe University Frankfurt, Frankfurt Am Main, Germany; Frankfurt Isotope and Element Research Center (FIERCE), Goethe University Frankfurt, Frankfurt am Main, Germany) - Madgwick, Richard (School of History, Archaeology and Religion, Cardiff University, Cardiff, United Kingdom) - Coppa, Alfredo (Department of History Anthropology Religions Performing Arts, Sapienza University of Rome, Rome, Italy) - Benazzi, Stefano (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy)

Advancements in archaeological sciences through innovative scientific techniques applied to ancient human remains have been increasingly transforming the study of the past. Micro-destructive analyses of human bioarchaeological or palaeontological specimens (e.g., dental histology, stable and radiogenic isotope analyses – at high-spatial resolution or with a bulk approach – serial sampling of dentine, trace element analysis of dental mineralised tissues, 14C dating, proteomic analysis, and ancient DNA) are today pervasive methodologies in bioarchaeological research. Notably, mineralized dental tissues, and especially dental enamel, have proven to be optimal for opening a window on individual life histories. The main issue of these techniques is the need for destructive sampling. Nonetheless, without these analyses, the depth of our understanding of the past would not have been as refined. In this context, in compliance with the ALARA standard (As Low [damage] As Reasonably Achievable), we present a standardized protocol for the optimization of tooth sampling for histology and biogeochemical analyses applied to a sample of $n = 29$ human teeth from the Villanovan necropolis of Sala Consilina (Early Iron Age, Campania, southern Italy). The proposed protocol enables the collection of multiple high-resolution evidence from minimal sampling of a single dental specimen, ensuring the preservation of most of the tooth and possibly of its morphology, and overall balancing scientific investigation

with the conservation of valuable archaeological and paleontological specimens guaranteeing the feasibility of future analyses.

5 HOW LONG IN THE TOOTH? DISCUSSING THE TRIALS AND TRIBULATIONS OF MULTI-SAMPLING HUMAN TEETH FOR ISOTOPE ANALYSIS

Griffith, Jacob (Archaeology, Environmental Changes, & Geo-Chemistry Research Group (AMGC), Vrije Universiteit Brussel (VUB), Brussels, Belgium.) - Schulting, Rick (Research Laboratory for Archaeology and the History of Art, School of Archaeology, University of Oxford, Oxford, UK.) - James, Hannah (Archaeology, Environmental Changes, & Geo-Chemistry Research Group (AMGC), Vrije Universiteit Brussel (VUB), Brussels, Belgium.) - Geritzen, Carina (Archaeology, Environmental Changes, & Geo-Chemistry Research Group (AMGC), Vrije Universiteit Brussel (VUB), Brussels, Belgium.) - Veselka, Barbara (Archaeology, Environmental Changes, & Geo-Chemistry Research Group (AMGC), Vrije Universiteit Brussel (VUB), Brussels, Belgium.) - Zariņa, Gunita (Institute of Latvian History, University of Latvia, Riga, Latvia.) - Ordoño, Javier (Department of Archaeology and New Technologies, Arkikus, Spain.) - Črešnar, Matija (Centre for Interdisciplinary Research in Archaeology, Department of Archaeology, Faculty of Arts, University of Ljubljana, Ljubljana, Slovenia.) - Snoeck, Christophe (Archaeology, Environmental Changes, & Geo-Chemistry Research Group (AMGC), Vrije Universiteit Brussel (VUB), Brussels, Belgium.)

In the past 20 years, bioarchaeological development has led to a greater understanding of human tooth formation and growth. Alongside the development of bioarchaeological techniques (i.e., isotope, proteomic, and DNA analyses), we can now recreate the lifeways of past individuals better than ever before. Currently, numerous multi-sampling techniques are being proposed for isotopic analysis, including incremental dentine sampling (slicing or puncturing), incremental enamel sampling, and in-situ analyses, meaning that dietary and mobility history changes can now be observed across the period of tooth formation.

However, issues surrounding which technique is appropriate to use or prioritise, are beginning to emerge. Whilst robust, human teeth hold a limited volume of material, meaning that all forms of analysis can rarely be applied. Further, many of these techniques have been developed on modern, unworn teeth. Applying them to archaeological, often worn, teeth is also complicated, with techniques requiring adaptation, or being impossible altogether.

This paper combines the multi-sampling (enamel and dentine) and multi-isotope data from multiple archaeological sites: Zvejnieki burial ground, (Mesolithic/Neolithic Latvia), Legaire Sur (Neolithic/Chalcolithic, Spain), Wilsford Henge (Bronze Age, England), Staje (Iron Age, Slovenia), and Koekelberg cemetery (Post-Medieval, Belgium). We review what techniques were appropriate to apply; where, how, and how much to sample, how successful they were, and what the limitations of the techniques were. The overall aim of this study is to navigate how to appropriately acquire the most lifeway data from a singular tooth, whilst being as minimally destructive as possible.

6 UNRAVELLING HORMONAL HISTORIES: PRELIMINARY FINDINGS FROM A NOVEL METHOD TO DETECT REPRODUCTIVE HORMONES IN HUMAN REMAINS USING ENZYME IMMUNOASSAY ANALYSIS

Barlow, Aimee (University of Sheffield) - Hemer, Katie (University College London) - Craig-Atkins, Elizabeth (University of Sheffield)

To date, the only hormone that has been detected in human hard tissues is cortisol, using Enzyme-Linked Immunosorbent Assay (ELISA) analysis (Nejad and Jeong, 2016; Quade, Chazot and Gowland, 2021; Quade et al., 2023). However, other steroid hormones (e.g. progesterone) have been identified in the baleen plates, teeth, and tusks of marine mammals (e.g. Hunt et al., 2017; Hudson, Matthews and Watt, 2021), suggesting that it could be possible to detect reproductive hormones in human dental structures. If successfully detected in humans, the hormones oestrogen, progesterone and testosterone hold the potential to provide an insight into the fertility and reproductive histories of past populations, thus opening opportunities to further explore concepts such as the mother-infant nexus. Progesterone is of particular interest as it is a known biomarker of pregnancy, detectable in blood serum, hair, saliva, and urine. Currently, there are no standardised protocols for the preparation of teeth, bones and calculus for ELISA analysis. Furthermore, oestrogen, progesterone and testosterone have not previously been investigated in human hard tissues.

Here, we will present a novel method for the preparation of archaeological bone, dental calculus, dentine and enamel for ELISA analysis. This method enables the identification of multiple reproductive hormones. To investigate whether hormones could be used as a marker of pregnancy in skeletal remains, 10 individuals were analysed as part of this study; two females with in utero fetal remains, two females associated with fetal remains, alongside three males and three females (determined via aDNA analysis) who act as controls. Oestrogen, progesterone and testosterone were detectable in tooth structures and bone samples. In addition, progesterone and testosterone were detectable in dental calculus. This presentation will explore the preliminary results and interpretation of this multidisciplinary study, and discuss the challenges faced when conducting ELISA analysis on human bone and teeth.

7 'THE AGE OF WISDOM'. EXPLORING AGE-AT-MENARCHE IN WOMEN'S WISDOM TEETH: A TOOL FOR THE BIOARCHAEOLOGICAL STUDY OF FEMALE REPRODUCTIVE LIFE-HISTORIES

Gigante, Melania (Department of Cultural Heritage, University of Padua, Padua, Italy) - Cerrito, Paola (Department of Evolutionary Anthropology, University of Zürich, Zürich, Switzerland) - Bondioli, Luca (Department of Cultural Heritage, University of Padua, Padua, Italy); Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy) - Lugli, Federico (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany; Frankfurt Isotope Element Research Center (FIERCE), Goethe Universität at Frankfurt, Frankfurt am Main, Germany; Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Modena, Italy) - Mahoney, Patrick (School of Anthropology and Conservation, University of Kent, Kent, United Kingdom) - Anczkiewicz, Robert (Institute of Geological Sciences, Polish Academy of Science Research Centre, Cracow, Poland) - Müller, Wolfgang (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany; Frankfurt Isotope Element Research Center (FIERCE), Goethe Universität at Frankfurt, Frankfurt am Main, Germany) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy)

Compared to other primates, humans undergo a complex and longer period of postnatal maturation and growth. Postnatal ontogeny is divided into stages, each characterised by the attainment of peculiar physiological, cognitive, behavioural, and reproductive milestones.

Puberty is a crucial stage of growth, marking the onset of sexual maturity and adult social life. In girls, puberty is marked by the onset of menarche (i.e., first menstruation cycle), which represents a crucial milestone in women's reproductive life-history.

Age-at-menarche is determined by an interplay of genetic and environmental factors, as an adaptive response to maximise female reproduction opportunities. Variations in the age-at-menarche is a sensitive measure for assessing women's health, as well as for estimating the impact of both environmental changes and human behaviours on female reproductive life-history across space and time.

Although the secular trends of the age-at-menarche in women from contemporary societies are well-known, there are still significant gaps in our understanding of how female reproductive scheduling has changed in recent human evolution. Traditional bioarchaeological approaches to reconstructing puberty rely on skeletal and dental maturation, albeit with some limitations.

This contribution presents the preliminary results of the first multiproxy study on the wisdom teeth (i.e., the third permanent molars) for reconstructing the evolution of menarche in past skeletal populations. Using dental histology and LA-ICPMS (laser ablation inductively coupled plasma mass spectrometry), we identified variations in Sr/Ca and Ba/Ca elemental profiles at the onset of first menstruation in $n = 2$ contemporary women with known life-histories. The identification of these biochemical markers opens up an unexplored avenue for unravelling the timing of first menstruation in past human populations, which may contribute to the question of how current life-history trajectories evolved.

8 BLOOD OF MY BLOOD: MATERNAL HEALTH AND DIET INFERRED FROM HIGH-RESOLUTION HISTOLOGY-DRIVEN, BIOGEOCHEMICAL ANALYSIS OF PRENATAL DECIDUOUS TOOTH ENAMEL

Galbusera, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy; Department of Cultural Heritage: Archaeology and History of Art, Cinema and Music, University of Padua, Italy) - Higgins, Owen (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy; Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Lugli, Federico (Institut für Geowissenschaften Goethe-Universität, Frankfurt, Germany; Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy) - Anczkiewicz, Robert (Institute of Geological Sciences, Polish Academy of Sciences, research Centre in Kraków, Poland) - Coppa, Alfredo (Department of Environmental Biology, Sapienza University of Rome, Rome, Italy) - Benazzi, Stefano (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Bondioli, Luca (Department of Cultural Heritage: Archaeology and History of Art, Cinema and Music, University of Padua, Italy) - Müller, Wolfgang (Institut für Geowissenschaften Goethe-Universität, Frankfurt, Germany; Frankfurt Isotope and Element Research Centre (FIERCE), Goethe University Frankfurt, Germany) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy)

Deciduous teeth start forming early during pregnancy and the enamel that develops during the intra-uterine period permanently records information encompassing the mother's dietary habits, environment and potential physiological stresses during pregnancy. Indeed, the study of human prenatal dental enamel provides a wealth of information about the early moments of the mother-infant dyad. However, despite the great potential offered by the study of prenatal enamel, this field remains under-explored.

The present work aims to investigate the diachronic evolution of the mother-infant dyad taking advantage of an integrated approach involving high-temporal resolution histological and biogeochemical analyses using laser-coupled mass spectrometry (LA-ICPMS) on the prenatal enamel of 41 deciduous teeth selected from contemporary ($n=13$) and modern ($n=15$) individuals with known life histories, as well as from archaeological contexts ($n=13$). Histological results report enamel growth trajectories and crown formation times, but also the timing of physiological stresses expressed in the enamel as Accentuated Lines. The combination of histological and biogeochemical analyses can detect changes in trace element patterns throughout the individual's gestational life. Strontium (Sr), Barium (Ba) and Magnesium (Mg) are used as proxies for maternal diet allowing the estimation of the mother's trophic level during the last months of pregnancy. Moreover, the presence of heavy metals such as lead (Pb) can provide information on the mother's potential exposure to pollutants and their incorporation by the foetus during gestation.

This work offers a novel and nuanced view of the mother-infant nexus, not limited to the development and health of the infant, but also inferring on the mother's life, health and diet during pregnancy, as derived from the infant's prenatal dental tissue.

9 A BLESSING OR A CURSE: USING LEAD CONTAMINATION TO SUPPLEMENT SR/CA AND BA/CA STUDIES OF ROMAN INFANT NURSING PRACTICES

Oldershaw, Leigh (The Ohio State University) - Lugli, Federico (Laboratory of Osteoarchaeology and Paleoanthropology (BONEs Lab), Department of Cultural Heritage, University of Bologna, Italy; Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy) - Sperduti, Alessandra (Museum of Civilizations, Bioarchaeology Service, Italy) - Coppa, Alfredo (Department of History, Anthropology, Religion, Arts and Performing Arts, Sapienza University of Rome, Rome, Italy) - Guatelli-Steinberg, Debbie (Department of Anthropology, The Ohio State University, United States) - Bondioli, Luca (Department of Cultural Heritage, University of Padua, Italy; Department of Cultural Heritage, University of Bologna, Italy) - Anczkiewicz, Robert (Geochronology and Isotope Geochemistry Laboratory Institute of Geological Sciences Polish Academy of Sciences, Kraków, Poland) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Rome, Italy)

Bioarchaeological research provides vital information about infant health, breastfeeding, and weaning in past human populations. Recent examinations of Ancient Roman infant nursing practices have focused on using Laser Ablation-Inductively Coupled Plasma-Mass Spectrometry (LA-ICP-MS) time-resolved analyses of Sr/Ca and Ba/Ca, in tandem with traditional histological methods, to reconstruct individual weaning timelines. Here, we introduce the novel use of lead to supplement Sr/Ca and Ba/Ca weaning profiles in 52 molars from 48 individuals from across Roman Italy dating from the 1st-5th centuries AD. Lead exposure in Roman communities has been extensively documented, with potential exposure routes for infants including the consumption of drinking water from lead pipes, tanks, and water containers, foods containing lead based preservatives and sweetening agents, wines, juices boiled in lead or pewter cauldrons (including the herbed grape juice syrup Sapa), drugs, and elixirs. Given the degree of lead pollution to which many Roman populations were exposed, lead provides a solid secondary means of identifying supplementation in the infant diet. Utilizing multiple sources of evidence for weaning behavior as shown here provides more reliable interpretations of infant nursing practices in the past.

10 TESTING ISOTOPIC AND ELEMENTAL APPROACHES TO DOCUMENTING NURSING BEHAVIOUR IN THE TEETH OF LIVING CHILDREN

Smith, Tanya (Griffith Centre for Social and Cultural Research, Griffith University, Australia; Australian Research Centre for Human Evolution, Griffith University, Australia) - Ávila, Janaína (Griffith Centre for Social and Cultural Research, Griffith University, Australia; School of the Environment, University of Queensland, Australia) - Arora, Manish (Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, USA) - Austin, Christine (Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, USA) - Sudron, Emma (Griffith Centre for Social and Cultural Research, Griffith University, Australia; Australian Research Centre for Human Evolution, Griffith University, Australia) - Wang, Yue (Research School of Earth Sciences, Australian National University, Australia) - Williams, Ian (Research School of Earth Sciences, Australian National University, Australia)

Scholars employ knowledge of tooth chemistry and development to document the weaning process in recent humans and fossil hominins. Nitrogen isotopes ($\delta^{15}\text{N}$) are the most widely used system. Conventional methods involve sampling dentine from sequential 1 mm thick sections; this produces an averaging effect where each section integrates months of formation. Similarly coarse studies of oxygen isotopes ($\delta^{18}\text{O}$) have also suggested a parallel oxygen-18 enrichment during nursing. Others have examined calcium-normalized barium (Ba/Ca) and strontium (Sr/Ca) distributions with laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS). Here we employed a Sensitive High Resolution Ion Microprobe (SHRIMP) to sample dentine $\delta^{15}\text{N}$ and enamel $\delta^{18}\text{O}$ values on a weekly-to monthly-basis along the developmental axis in M1s of two healthy children from Australia and New Zealand. We

also created comprehensive Ba/Ca and Sr/Ca maps with LA-ICP-MS. By relating sample positions to enamel growth lines, we identified the initiation of suckling at birth, as well as the ages of postnatal samples over more than three years. We found rapid postnatal dentine $\delta^{15}\text{N}$ increases of ~ 2 - 3 ‰ while the children were exclusively breastfed, followed by gradual declines as the frequency of breastfeeding decreased until weaning was complete. Enamel $\delta^{18}\text{O}$ values did not show a similar oxygen-18 enrichment during nursing, consistent with SHRIMP studies of nonhuman primates. Barium did not show an immediate postnatal increase, but rose after a few months until ~ 1 - 1.5 years of age, then fell until or shortly after the cessation of suckling, as expected. Strontium unexpectedly remained low beyond the period of exclusive suckling, eventually rising and remaining high long beyond the cessation of nursing. High-resolution $\delta^{15}\text{N}$ measurements minimize time averaging and can be precisely related to nursing histories. In buried teeth with poor collagen preservation, Ba/Ca distributions are the most promising alternative for estimating weaning ages.

11 GROWTH PATTERNS AND DEVELOPMENTAL TRAJECTORIES OF FIRST DECIDUOUS MOLARS: A MULTIDISCIPLINARY APPROACH COMBINING HISTOMORPHOMETRIC AND AMELOGENIN ANALYSES

Magri, Stefano (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Higgins, Owen (Department of Cultural Heritage, University of Bologna, Ravenna, Italy; Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Italy) - Lugli, Federico (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany; Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Modena, Italy) - Silvestrini, Sara (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Vazzana, Antonino (Department of Cultural Heritage, University of Bologna, Ravenna, Italy) - Bondioli, Luca (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Italy) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome, Italy) - Benazzi, Stefano (Department of Cultural Heritage, University of Bologna, Ravenna, Italy)

The pace and temporal patterns of dental tissue development provide significant insights into both individual and populational ontogenetic pathways and biological rhythms. The systematic, rhythmic, and appositional development of dental mineralized tissues enables direct quantification of individual growth rates and odontogenic patterns. A quantification that has largely been explored for permanent dentition but is still limited for the deciduous teeth. Additionally, the application of histomorphometric analysis in conjunction with enamel proteomics offers enhanced insight into potential diversification in developmental trajectories, allowing sex determination even in immature individuals.

This study combines results from histomorphometric and amelogenin analyses conducted on 34 first deciduous molars selected from the geographically proximate Early Medieval Italian necropolises of Casalmoro and Guidizzolo (Mantua, Italy). The findings reveal a notable consistency in the daily secretion rates of inner enamel across dental arches and sexes, and between the two necropolises, reflecting closely data from archaeological populations. However, a marked contrast was observed when comparing these rates with those of published modern populations. Additionally, initiation of enamel matrix deposition was found to occur earlier in maxillary first molars than in mandibular molars, with variations in crown formation times and ages at crown completion between dental arches. Notably, no significant sex-related differences were detected.

The collection of enamel developmental data enabled the development of a robust linear model, resulting in a regression formula specifically designed for pre-industrial populations. This formula facilitates the tailored reconstruction of odontogenic trajectories, even in cases where enamel microstructure may be partially obscured.

In conclusion, this methodological investigation significantly enhances our understanding of the growth and development of first deciduous molars, exploring potential differences between sexes and between two contemporaneous, neighbouring groups. These findings underscore the efficacy of an integrated approach, allowing a more nuanced comprehension of developmental processes in past populations.

12 TOOTH HISTOLOGY AND STABLE OXYGEN AND STRONTIUM ISOTOPE PROFILES TO RESOLVE A CLIMATE-STRESS-RELATIONSHIP OVER INDIVIDUAL HUMAN EARLY LIFE COURSES

Witzel, Carsten (Department of Biology, University of Hildesheim, Germany) - Fauth, Inga (Department of Biology, University of Hildesheim, Germany) - Wang, Yue (SHRIMP Facility, Research School of Earth Sciences, Australian National University, Canberra, Australia) - Williams, Ian (SHRIMP Facility, Research School of Earth Sciences, Australian National University, Canberra, Australia) - Knowles, Brett (ICP-MS Facility, Research School of Earth Sciences, Australian National University, Canberra, Australia) - Darabi, Hojjat (Institute of Archaeology, Razi University, Kermanshah, Iran) - Soltysiak, Arkadiusz (Department of Bioarchaeology, Faculty of Archaeology, University of Warsaw, Poland)

Hot and dry climate conditions will cause the preferential evaporative loss of ^{16}O in environmental water, food items, and the bodies of animals and humans. In the enamel of human tooth crowns several years of growth are recorded

and the analysis of incorporated stable oxygen isotope ratios ($\delta^{18}\text{O}$ ‰ VSMOW) allow for the assessment of such fluctuations in that high (or more positive) values account for dry seasons or periods. The high-resolution recording of $\delta^{18}\text{O}$ -values in enamel of sectioned teeth along the enamel-dentine junction enables the identification of successively occurring highs and lows. Establishing the chronology of crown formation by using incremental features in enamel will date these successions and an analysis of correspondence with developmental disturbances both on the macroscopic and microscopic scale could be performed.

We analysed human canines recovered from the Neolithic (7500-7200 cal. BC) site of Ali Kosh, Iran. Four teeth of different individuals, two of them exhibiting a pattern of multiple linear enamel hypoplasia (LEH) indicative of seasonal disturbances, were embedded and axiobuccolingually sectioned. Section surfaces were either prepared as microscopic thin sections or investigated in a Sensitive High-Resolution Ion Micro-Probe (SHRIMP) for their $\delta^{18}\text{O}$ -values. To exclude a modification in these values due to a change of the source of drinking water we will also measure sequential in situ profiles of $^{87}\text{Sr}/^{86}\text{Sr}$ values by mass spectrometry (LA-ICP-MS).

Measured $\delta^{18}\text{O}$ -values ranged between 16.01 and 23.22. Especially the teeth with consecutive LEHs exhibited up to 5 profile peaks. An in-depth analysis of the chronology of the sampling locations (resolve timing below a month) and areas of disturbed enamel formation will shed light on the affection of tooth formation of individual humans living through these fluctuations and thereby on the relationship between climate conditions and developmental stress.

13 HIGH SPATIAL RESOLUTION MEASUREMENTS OF SR ISOTOPES AND TRACE ELEMENT ABUNDANCE IN DENTAL TISSUES: IMPLICATIONS FOR MOBILITY AND SEASONALITY STUDIES

Anczkiewicz, Robert (Polish Academy of Sciences, Institute of Geological Sciences, Poland) - Nava, Alessia (Sapienza University of Rome, Italy) - Bondioli, Luca (University of Bologna, Ravenna, Italy) - Spötl, Christoph (University of Innsbruck, Austria) - Lugli, Federico (Goethe-Universität, Frankfurt, Germany) - Posth, Cosimo (University of Tübingen, Germany) - Müller, Wolfgang (Goethe-Universität, Frankfurt, Germany) - Dądela, Maria (Polish Academy of Sciences, Institute of Geological Sciences, Poland) - Koziarska, Marta (Polish Academy of Sciences, Institute of Geological Sciences, Poland)

Bio-apatite, the main skeleton-forming compound, assimilates via food and water a wide range of trace elements whose abundance and isotopic composition reflect in vivo processes. Although there is little doubt about dental enamel being the most resilient to post-depositional changes tissue, sampling strategies and analytical approaches are debatable. Considering the prolonged time of mineralization of dental tissues, high spatial resolution techniques became methods of choice. Among them, laser ablation coupled with single and/or multi-collector inductively coupled plasma mass spectrometers (LA (MC)-ICP-MS), permitting simultaneous measurements of a wide range of elements and precise analyses of Sr isotope composition, belong to the most commonly used. In this study, we combined histomorphometry with LA (MC) ICP-MS to select the optimal sampling side in dental tissues. Using matrix-matched standardization, we evaluated the precision and accuracy of Sr isotope composition and trace element concentration measurements. Furthermore, we tested the effect of maturation on obliterating the earliest, secretion stage, biogenic signature and evaluated the reliability of trophic level indicators. Supporting trace element abundance measurements with high spatial resolution Sr and O isotope composition determination, we verified trace element usability for seasonality studies. We showcase the established methodology by studying woolly mammoth mobility patterns in Central and Eastern Europe throughout the Upper Palaeolithic.

14 A MULTI-PROXY ANALYSIS OF LIFE AND DEATH HISTORIES AT MAYA ARCHAEOLOGICAL SITES: INTRODUCING THE ISO-HISTOLOGICAL APPROACH

Rand, Asta (School of History, Archaeology and Religion, Cardiff University) - Madgwick, Richard (School of History, Archaeology and Religion, Cardiff University)

The reconstruction of individual life histories has a long tenure in prehispanic Maya archaeology. This research now regularly incorporates the analysis of strontium, carbon, nitrogen and most recently sulfur isotopes that contribute nuanced understandings of Maya subsistence practices and migration processes. While such studies have built a better understanding of prehispanic Maya lived experiences, especially when combined with osteological data, the cultural and taphonomic processes that occurred after death have received less attention. This may be because Maya mortuary behaviours were complex, ranging from immediate burial, to bundling, excarnation, exhumation, display, and curation of human bodies or their parts, depending on what the deceased represented to the living. These past behaviours have a direct impact on the interpretation of isotopic data from human skeletal remains as well as the degree to which they have been impacted by diagenesis. While diagenetically altered samples are typically discarded because they cannot speak to an individual's life history, their isotopic data may offer the key to reconstructing their death histories. Here, we present a multi-proxy framework that combines histology and multiple isotope analyses into an iso-histological approach for understanding not only the life histories of Maya individuals, but also what happened to their bodies after death. The results will provide important insights into prehispanic Maya mortuary behaviour and help

to refine understandings of Maya subsistence and migration, while demonstrating how the iso-histological method may be applied more broadly in other archaeological and forensic contexts.

15 LIFE HISTORY RECONSTRUCTIONS OF ENSLAVED AFRICANS IN CARIBBEAN COLONIAL CONTEXTS

Laffoon, Jason (Leiden University)

Isotope analysis has proven highly effective owing to the fact that it can provide direct evidence of individual behaviors and thereby permits investigations of inter-individual differences. Traditional isotope paleodiet studies have generally relied on a single bone sample per individual to make inferences about long-term (years to decades) average dietary intake at the end of an individual's life (usually of adults). More recently, there has been increasing research interest in using serial sampling of incrementally growing tooth dentine as it allows for the study of dietary change at much higher temporal resolution (months). Additionally, isotope studies of paleomobility have also become commonly employed and effective tools for investigating human and animal mobility patterns and. Multiple isotope studies of human dental enamel coupled with better understanding of spatial isotopic variation permit more reliable identification of nonlocal migrants and improved assessments of geographic origins. This paper presents the preliminary results of an ongoing project utilizing multiple isotope analyses of dental enamel and incrementally sampled dentine of individuals from enslaved contexts in the Caribbean region. These include the identification of a very high proportion of first generation migrants; indications of extremely diverse origins, assessments of the age of migration, and reconstructions of migration-related dietary change. The paper also explores some of the major limitations of such studies to date, including the limited precision of geographic provenance assignments and problems linking isotope values to specific ages within an individual lifetime.

16 SCORCHING THE SURFACE: CREATING MORE NUANCED LIFE MOBILITY HISTORIES OF THE CREMATED DEAD

Loeffelmann, Tessi (Archaeology, Environmental Changes & Geo-Chemistry, Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium; Department of Archaeology, Durham University, South Road, Durham, DH1 3LE, UK) - Snoeck, Christophe (Archaeology, Environmental Changes & Geo-Chemistry, Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium) - Claeys, Philippe (Archaeology, Environmental Changes & Geo-Chemistry, Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium) - Montgomery, Janet (Department of Archaeology, Durham University, South Road, Durham, DH1 3LE, UK)

Strontium isotopes ($^{87}\text{Sr}/^{86}\text{Sr}$) and concentrations ($[\text{Sr}]$) are a useful proxy to investigate the mobility of individuals from a wealth of archaeological contexts. From bedrock lithologies, strontium weathers into overlying soils and water, and is taken up by plants. The element is then integrated into skeletal tissues of those animals and humans who are eating these plants or drinking the water. This process enables bioarchaeologists to look at whether people moved during or after childhood (tooth enamel). More recently, the method has been developed to include the analysis of cremated bone, which, when fully calcined, is resistant to diagenetic exchanges with the soil. This has led to a wealth of new isotope data, covering many archaeological periods and locations.

At the same time, the use of cremated bone for strontium isotope analysis requires a specific repertoire of knowledge which takes into account other challenges than those that apply to uncremated remains. This includes knowledge of bone remodelling mechanisms which are tied to many factors, such as age, sex, and the health status of the individual. In order to move away from very generalised interpretations of strontium data, these factors should be considered where possible and integrated into the life-history reconstruction of cremated individuals. This presentation uses $^{87}\text{Sr}/^{86}\text{Sr}$ and $[\text{Sr}]$ data from different skeletal elements (otic capsule, femur, tibia, rib, and cranium), in conjunction with information from the osteological analysis of 54 individuals from the early medieval cremation cemetery at Cleatham (Lincolnshire, UK), to highlight how individual mobility histories can be explored in a more nuanced way.

17 ISOTOPES AND PEPTIDES. THE MULTI-DISCIPLINARY STUDY OF THE MIDDLE IRON AGE NECROPOLIS OF CUS-PIOVEGO, PADUA, ITALY

Capasso, Giusy (Department of Cultural Heritage, University of Padova, Italy) - Lugli, Federico (Institut für Geowissenschaften, Goethe-Universität Frankfurt am Main, Germany; Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy) - Armadori, Elena (Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy) - Cipriani, Anna (Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy) - Madgwick, Richard (School of History, Archaeology and Religion, Cardiff University, UK) - Prillo, Vito (Department of Cultural Heritage, University of Padova, Italy) - Gigante, Melania (Department of Cultural Heritage, University of Padova, Italy) - Bondioli, Luca (Department of Cultural Heritage, University of Bologna, Ravenna, Italy; Department of Cultural Heritage, University of Padova, Italy) - Vidale, Massimo (Department of Cultural Heritage, University of Padova, Italy) - Cupitò, Michele (Department of Cultural Heritage, University of Padova, Italy)

Since the end of the 19th century, the phenomenon of bi-ritualism in Iron Age Veneto has been the subject of considerable interest. Although cremation was the predominant burial practice, a considerable number of inhumations are also attested. Significant differences between inhumation and cremation burials, such as the almost exclusive association of wealthy grave goods with cremations - whereas these are very simple or absent in inhumations - have led to the hypothesis that inhumation rites might have been reserved for individuals of low social status or different origin. The CUS-Piovego necropolis (half of the 6th century B.C. - first half of the 4th century B.C.) is the largest bi-ritual necropolis in pre-Roman Padua. The integration of archaeological, osteological, isotopic, and palaeoproteomic data provides new insights into the individual life histories of individuals buried at the site.

Amelogenin analysis of dental enamel of $n=19$ inhumed individuals confirmed osteological sex estimates in 100% of cases while assessing the sex in subadults.

$^{87}\text{Sr}/^{86}\text{Sr}$ isotope analysis performed on M1 tooth enamel of $n=22$ inhumed individuals and petrous bone of $n=45$ cremated individuals identifies 19.4% of individuals as 'non-local' ($n=13$), with a higher prevalence in inhumations ($n=8$, 36.4% vs. $n=5$ cremations, 11.1%). The integration of $^{87}\text{Sr}/^{86}\text{Sr}$ and $\delta^{18}\text{O}$ isotope data characterises the Alpine region as the most likely area of origin for non-locals. The $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ isotope analysis of rib bones of $n=19$ inhumed individuals reveals a relatively poor diet, primarily consisting of C3 and C4 cereals.

The higher prevalence of non-locals and the evidence of poor diet and trauma in some of the inhumed individuals suggest that these might have pertained to a lower status.

Through a multi-proxy approach to the study of ancient human societies, this research provides a deeper understanding of social structures and mobility dynamics in Middle Iron Age Veneto.

18 VIRTUAL BONE HISTOLOGY FOR THE ASSESSMENT OF LIFE HISTORY: A MULTIMODAL APPROACH FOR THE CHARACTERISATION OF KRAPINA NEANDERTHAL SKELETAL MICROSTRUCTURE

Lemmers, Simone (Elettra Sincrotrone Trieste S.C.p.A.; Harvard Medical School; Center for Genomic Medicine, Massachusetts General Hospital) - Nava, Alessia (Department of Odontostomatological and Maxillofacial Sciences, Sapienza University of Rome) - Bondioli, Luca (Department of Cultural Heritage, University of Padua) - Radovic, Davorka (Croatian Natural History Museum) - Mahoney, Patrick (School of Anthropology and Conservation, University of Kent) - Mancini, Lucia (Slovenian National Building and Civil Engineering Institute (ZAG)) - Drossi, Diego (Elettra Sincrotrone Trieste S.C.p.A)

Human bone microstructure preserves information on an individual's growth, life history variables, age-at-death estimation, diet, pathologies, and activity patterns. Therefore, it is extremely valuable in archaeological contexts, preserving information through deep time. Although conventional palaeohistology requires sectioning of bone specimens for microstructure assessment, virtual histology, using synchrotron X-ray computed microtomography (μCT), allows non-destructive analysis, opening opportunities for assessing precious materials, including those of early Homo. However, bone microstructure analysis can be severely hampered due to varying levels of diagenesis, which can lead to microstructure destruction and challenge performing successful μCT imaging. In this contribution, we discuss the first results of the virtual bone histological analysis of an important set of Neanderthal skeletal remains from the site of Krapina (Croatia, ca 130 ka), obtained at the Elettra synchrotron in Trieste (Italy). We present a multimodal approach, using lab-based and synchrotron X-ray μCT for the analysis of Krapina long bones and ribs. We also provide preliminary results of complementary techniques (FTIR and XRD) on faunal remains from the same contexts, allowing us to comment on the preservation status of the material, mineralisation levels, and the quality of the data obtained. We then proceed to discuss the opportunities and limitations of using virtual bone histology for life history reconstruction in the context of human evolution. Although paleo-bone histology has been successfully incorporated into the evolutionary study of other vertebrate groups, examining bone microstructure to decipher ontogenetic patterns,

maturational timing, and physical activity has rarely been employed in the study of the evolution of our own, human, lineage. Therefore, this presentation is meant as a discussion on how we can bring this field forward, drawing lessons from the Krapina collection, outlining the next steps of life history analysis, and suggesting possible applications to future collections for the study of human life history evolution.

19 SEX ESTIMATION AND PHYLOGENETIC CHARACTERIZATION OF PLEISTOCENE FAUNAL ENAMEL

Parker, Glendon (University of California - Davis, USA) - Egeuz, Natalia (University of California - Davis, USA; Universidad de La Laguna, Spain) - Burk, Kyle (University of California - Davis, USA) - Buonasera, Tammy (University of Alaska - Fairbanks) - Eerkens, Jelmer (University of California - Davis) - Morales, Jessica (University of California - Davis) - Eubanks, Jill (University of California - Davis) - Stafford, Thomas (Stafford Research LLC) - McDonald, Greg (retired) - Spicer, Ashley (California Department for Fish and Wildlife)

Hominin hunting practices comprise a dynamic interplay of human behavior, ecological availability and resource optimization. Deconvolution of these factors often depends on using fragmentary skeletal material to identify the species and sex of hunted animals. Here we report that fragmentary enamel can be processed to detect amelogenin peptides that are Y- and X-chromosome biomarkers, which can be detected through proteomic mass spectrometry. Initially developed for human sex estimation, the analysis can also be applied to faunal species. Sex chromosome-specific markers have been identified and characterized for a range of relevant prey species and carnivores. A precondition of proteomic mass spectrometry is that accurate protein amino acid sequences are elucidated for use in reference proteomes. Currently, faunal amelogenin sequences are inaccurate, poorly annotated, and incomplete. The authors, therefore, conducted a systematic bioinformatic analysis of the X- and Y-chromosome amelogenin sequences of respective species. These sequences were used in conjunction with sample processing and proteomic mass spectrometry methods developed for human proteomic sex estimation. Sex estimation was successfully conducted on faunal enamel (20 mg) from Pleistocene contexts: *Bison cf. priscus*, *Bos primigenius* (Auroch), *Canis lupus* (Wolf), *Ursus spelaeus* (European cave bear), *Mammuthus primigenius* (Woolly Mammoth), and *Mammuth americanus* (American Mastodon). Sex estimation was also conducted on modern exemplar species: *Bison bonasus* (European bison), *Bos taurus*, *Canis lupus familiaris*, *Ursus arctos arctos*, and *Odocoileus hemionus californicus*. In this study, data were obtained across a 400,000 year time frame. The analysis also provides phylogenetic information, to at least the taxonomic level of Family. This approach also makes it possible to determine the sex of mammalian taxa that are not obviously morphologically sexually dimorphic. In this way, information from enamel fragments contributes to a deeper understanding of prey selection and the complex interactions between human hunters and their environment.

20 SEASONALITY OF RED DEER (*C. ELAPHUS*) REVISITED USING TOOTH CEMENTUM ANNULATION AND ELEMENTAL ANALYSIS BY FIELD-EMISSION SEM-EDS

Boric, Dusan (Department of Environmental Biology, Sapienza University of Rome; Department of Anthropology, New York University) - Peripoli, Beatrice (Sapienza University of Rome) - Cristiani, Emanuela (Sapienza University of Rome) - Csorba, Gabor (Hungarian Natural History Museum) - Dimitrijevic, Vesna (Laboratory for Bioarchaeology, Faculty of Philosophy, University of Belgrade) - Hu, Bin (Department of Molecular Pathobiology, New York University College of Dentistry) - Bromage, Timothy (Department of Molecular Pathobiology, New York University College of Dentistry, New York, NY; Department of Anthropology, New York University; New York Consortium in Evolutionary Primatology) - Cerrito, Paola (Collegium Helveticum, ETH, Zürich)

Reliable means of determining the season-at-death in living organisms has for some time been important in fields as diverse as wildlife management and zooarchaeology. In this contribution, we focus on the study of tooth cementum annulation (TCA) in modern and subfossil specimens of red deer *Cervus elaphus*. Histological thin sections were prepared for 15 teeth from 14 modern male and female red deer individuals with known season-at-death found in different locations in the Carpathian Basin region of Hungary. We also analyzed 13 archaeological red deer teeth from Mesolithic (9600–6000 cal BCE) and Early Neolithic (6000–5500 cal BCE) layers of the sites of Lepenski Vir and Padina in the Danube Gorges region of Serbia. Environmental and climatic conditions, including seasonal variations and other external physiological stressors, are similar between the two study areas, making these two populations comparable. Transmitted light microscopy observations were used to estimate both age-at-death and season-at-death for all specimens. We find high inter-observer correspondence when estimating age-at-death but poor visibility of the outer edge of cementum and inter-observer correspondence when estimating season-at-death. We employed field-emission scanning electron microscopy and energy-dispersive X-ray (SEM-EDS) analysis on the same specimens to measure the relative concentrations of silicon, oxygen, phosphorus, calcium, sodium, magnesium, potassium, sulfur, and zinc. Elemental analyses indicate that seasonality is present in all teeth and all elements except for four elements in one specimen. To make predictions about season-at-death we used a machine-learning supervised classification algorithm known as random forest. We find 34.8% error rate in predicting season-at-death using

a four-season (fall-winter-spring-summer) classifier and significantly improved 1.7% error rate in predicting it using a two-season (summer-winter) classifier.

21 ANIMAL LIFE HISTORIES AND THE ECONOMY OF AN EARLY NURAGHE: ZOOARCHAEOLOGY AND ISOTOPE ANALYSIS AT SA CONCA 'E SA CRESIA

Holt, Emily (Cardiff University) - Madgwick, Richard (Cardiff University)

Understanding the animal economy of the early Nuragic Culture is an essential component of reconstructing the culture's socioeconomic foundations. The site of Sa Conca 'e sa Cresia, an archaic nuraghe (c. 1750-1300 BCE) located on the Siddi Plateau in the Marmilla region of south-central Sardinia, provides an opportunity to investigate how animals were raised, transported, and consumed at an early Nuragic settlement. Ongoing excavations at Sa Conca 'e sa Cresia have recovered thousands of faunal remains that are the subject of the research project ZANBA: ZooArchaeology of the Nuragic Bronze Age. ZANBA combines morphological analysis of Sa Conca 'e sa Cresia's faunal assemblage with carbon, nitrogen, and strontium analysis of domesticated animal remains to assess hunting, animal husbandry, and patterns of mobility at the site. The results from ZANBA contribute to new understandings of the changing economic strategies practiced at an early Nuragic site, as well as their relationship to the growth of power at the site.

22 UNDERSTANDING ANIMAL LIFE HISTORIES AND BIOCULTURAL ADAPTATIONS TO CHALLENGING ENVIRONMENTS THROUGH MULTI-ISOTOPE ANALYSIS OF NEONATAL FAUNAL REMAINS

Jones, Jennifer (University of Central Lancashire; Evoadapta Research Group, University of Cantabria) - Mulville, Jacqui (Cardiff University)

Neonatal animals are frequently neglected in stable isotope archaeological research as they can skew baselines and mask trends due to the nursing effect. However, the application of stable isotope analysis of neonatal animals can be an invaluable tool to investigate the mothers of the neonatal animals when they were in utero, informing on how pregnant animals were treated during their gestation. This can help to establish individual life histories of animals, as well as biocultural adaptations in the management of domestic stock.

In the Outer Hebrides, on the West Coast of Scotland, UK, in the Bronze Age, Iron Age and Norse periods the zooarchaeological assemblages are characterised by large numbers of neonatal and infant animal remains (up to 20%). Discussions centre on whether this is due to poor management strategies and insufficient fodder provision in these challenging environments, or deliberate culling linked to resource management or milking strategies.

Here 91 cattle and sheep bone collagen specimens (aged between foetal up to 3 months) from the sites of Cladh Hallan and Bornais, dating from Bronze Age, Iron Age and Norse period are analysed for $\delta^{13}C$, $\delta^{15}N$ and $\delta^{34}S$. Results show that individual diet of sheep was highly varied, with some individuals having access to seaweed in pregnancy and others not, suggesting less formal stock management. Clear differences in $\delta^{15}N$ between nursing animals and foetal animals informs on the relationship between parents and offspring. Cattle results suggest that they were consistently provided with terrestrial fodder, supporting the hypothesis that they were being carefully managed for milking.

The stable isotope analysis of juvenile and neonatal animal bone collagen helps to provide an holistic understanding of pastoral strategies in the past, informing on the life stories of individual animals as well as wider herd management.

23 STABLE ISOTOPE ANALYSES OF CATTLE TEETH FROM A NEOLITHIC EARTHWORK IN LOWER SAXONY, GERMANY: INSIGHTS INTO BIRTHING SEASONS AND MOBILITY

Knipper, Corina (Curt Engelhorn Center Archaeometry, Mannheim) - Geschwinde, Michael (Independent researcher) - Grefen-Peters, Silke (ossatura.de)

Monumental earthworks are prominent archaeological sites of the central European younger Neolithic. A center of their distribution are the northern German lowlands northwest of the Harz Mountains in Lower Saxony. Aerial prospections revealed over 30 of these sites. They consist of ditches of at least 1500 m length, which encircle areas of seven hectares and more and date to between ca. 4100 and 3400 cal. BC. Extensive collections of faunal remains recovered from the ditches of the earthworks provide evidence for slaughtering livestock and point to a function of the sites in a possibly mobile system of animal husbandry. Oxygen and strontium isotope analyses on serially sampled cattle teeth are well-established approaches to explore herding in geologically different landscapes and linking it to the seasonal cycle. These methods are currently applied to cattle teeth from the site of Niedersickte. So-called "re-cuttings" into pre-existing ditches of this Younger Neolithic earthwork revealed numerous faunal remains. The presentation will introduce stable isotope data of 18 well-selected cattle teeth, representing different animal individuals. Indication of opposing birthing seasons implies varying availability of meat and dairy products over the year.

Moreover, linking strontium isotope data to enamel formation in summer or in winter provides the basis for discussing the role of seasonal mobility of the herds.

24

TRACKING ARCHAEOLOGICAL SHEEP BREED DIVERSITY IN SOUTHWEST ASIA IN PALEOPROTEOMIC

Vuillien, Manon (Université Côte d'Azur, CEPAM, CNRS, Nice; AASPE, Muséum national d'Histoire naturelle, CNRS, Paris) - Bray, Fabrice (MSAP - Université de Lille, CNRS, USR3290) - Chahoud, Jwana (Archéorient, CNRS, University of Lyon 2; Department of Archaeology, Lebanese University) - Davoudi, Hossein (Bioarchaeology Laboratory, Central Laboratory, University of Tehran) - Fathi, Homa (Bioarchaeology Laboratory, Central Laboratory, University of Tehran) - Berthon, Rémi (AASPE, Muséum national d'Histoire naturelle, CNRS, Paris) - Al Besso, Moussab (Archéorient, CNRS, University of Lyon 2) - Mashkour, Marjan (AASPE, Muséum national d'Histoire naturelle, CNRS, Paris; Bioarchaeology Laboratory, Central Laboratory, University of Tehran) - Vila, Emmanuelle (Archéorient, CNRS, University of Lyon 2)

In the framework of the ANR EvoSheep project an exploratory study in paleoproteomics was carried out on wild and domestic sheep and goat bones from 14 Neolithic to Late Bronze Age sites distributed from Northern Levant to Eastern Iranian Plateau. The objectives were 1) to quantify the preservation degree of peptide chains contained in the COLA1 and COLA2 to confirm and complete the taxonomic identifications for geometric morphometrics analyses 2) to study the amino acid mutations sequences in the specific peptide chains and their evolution over time, from the wild ancestor to the first sheep breeds. This work is based on 70 samples, of which 66 correspond to archaeological specimens and 3 to modern species. Between 1 and 5 mg of bone powder was collected and treated according to the preparation protocol recently published by F. Bray and his team. Identifications were realized by MALDI-FTICR and LC-MS/MS.

MALDI-FTICR analysis identified collagen in 100% of the samples, validated and completed taxonomic identifications. The results correlated with 97% of the archaeozoologists identifications. Collagen quality was measured using the percentage of glutamine deamidation in modern (1.6% +/- 0.5%) and ancient (11% +/- 2.4%) samples. The results highlight a very good preservation of collagen in archaeological bones despite taphonomic conditions of burial, storage and handling. Archaeological sites climatic and environmental conditions did not have significant impact of deamidation value. The LC-MS/MS analyses performed identified more than 70% of the type I collagen sequence. Post-translational modifications were observed such as hydroxylations, acetylations but no mutation has been observed at this stage, but future investigations must be conducted to confirm this observation.

1004

TRACKING THE LIFE HISTORY THROUGH THE MICROARCHITECTURE OF THE HUMAN BONE

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Figus, Carla (Department of Cultural Heritage, University of Bologna, Ravenna Campus, Italy) - Colombo, Antony (Department of Life and Earth Sciences, Ecole Pratique des Hautes Etudes (EPHE) - Paris Sciences & Lettres Université (PSL) University, Paris, France; Unité Mixte de Recherche (UMR) 6034 Archéosciences Bordeaux, Centre national de la recherche scientifique (CNRS) - Université Bordeaux-Montaigne, Pessac, France) - Saers, Jaap (Naturalis Biodiversity Center, Vertebrate Evolution, Development, and Ecology, The Netherlands)

Session format: Regular session

Both cortical and trabecular bone microarchitectural studies play a crucial role when investigating developmental changes and behaviors from the first hominin species to the modern human populations. Trabecular bone, thanks to its rapid functional adaptation through efficient bone remodeling, has been proven useful in biological anthropology to better understand locomotor and manipulative behaviors, able to provide insights into patterns of physical activity and infer health conditions and processes as well as their modifications through the different stages of life.

On the other hand, the cortical bone, with its dense structure, is essential for understanding long-term loading and behaviors. Analyzing cortical bone can reveal adaptations to specific behaviors, helping to identify patterns of repetitive stress or strain on bones, and shedding light on activities like tool use, agriculture, or hunting.

In light of innovations in medical and 3D imaging, and advances in artificial intelligence for image processing, confronting or combining both trabecular bone and cortical bone studies - in addition to the classical bone external morphological analysis - offers a comprehensive approach to unraveling the complex interplay of biology and culture in human evolution and behavior. It is one of the very promising ways to better understand ontogeny, environmental adaptations, and cultural impact, and reconstruct behaviors and health in the past.

This session aims to bring together trabecular and cortical studies from different historical, geographical, and cultural backgrounds, promoting these works and the interaction among different research groups, with the purpose of fostering the exchange of ideas and knowledge.

ABSTRACTS

1 SKELETAL DEVELOPMENT PROVIDES NEW TOOLS TO RECONSTRUCT THE EVOLUTION OF HOMININ LOCOMOTION AND LIFE HISTORY

Saers, Jaap (Naturalis Biodiversity Center)

Modern human locomotion and its development are unique among the apes. Humans are bipedal, fully terrestrial, and develop slowly (altricial). The other apes are arboreal to varying extents and develop much quicker (precocial). It is likely that early hominins followed an ape-like developmental trajectory, with a mixed arboreal and terrestrial repertoire and precocial locomotor development. Investigating the nature of hominin locomotion and its development throughout hominin evolution requires reliable developmentally plastic traits that are responsive to locomotor loading and can be identified in the fossil record. Extant great apes provide a natural experiment to examine the relationship between age-related variation locomotor activities and bone structure: humans are fully terrestrial bipeds, chimpanzees and gorillas are highly arboreal as subadults and transition to terrestrial knuckle walking during ontogeny, finally, orangutans and gibbons remain predominantly arboreal throughout life.

In this paper I compare the development of bone structure in the ankle and shoulder of these five ape genera with varying locomotor repertoires and developmental trajectories. The objectives are 1) to determine if skeletal ontogeny reflects behavioural variation in arboreal locomotion among taxa, and 2) to test a previously proposed model where primate skeletal ontogeny was found to be strongly associated with brain development.

Results indicate a strong correspondence between age-related variation in locomotor repertoire and bone structure in extant apes. Developmental trajectories additionally correlate with brain development, further supporting the neuromuscular maturation model of bone development. Findings therefore suggest that analyses of hominin skeletal ontogeny can provide new insights into the evolution of two characteristic human traits: our slow rate of maturation and the evolution of fully terrestrial bipedalism.

2 INSIGHTS FROM THE TRABECULAR DEVELOPMENT OF THE JUVENILE HUMAN DISTAL TIBIA AND TALUS

Reid, Rebecca (Centre for Anatomy and Human Identification, University of Dundee) - Davies, Catriona (Centre for Anatomy and Human Identification, University of Dundee) - Cunningham, Craig (Centre for Anatomy and Human Identification, University of Dundee)

It is postulated that early trabecular form is under genetic control whilst skeletal loading drives changes in the post-natal skeleton. However, it remains unclear how factors such as vascularisation and ossification patterns influence the development of trabecular bone. By comparing two anatomically different bones that share similar locomotive demands, this study aims to investigate how developmental and biomechanical factors interact.

Forty-one tali and 69 distal tibiae from the Scheuer Collection, ranging from 28 intrauterine weeks to 8 postnatal years were microcomputed tomography scanned. Scaled volumes of interest (VOIs) were placed within the distal tibia and talus. Within each VOI, degree of anisotropy (DA), bone volume fraction (BV/TV), and trabecular thickness, trabecular separation, and trabecular number were quantified. VOIs were compared using Kruskal-Wallis H tests to assess trabecular heterogeneity at different stages of development. Mann Whitney-U tests and Independent T-tests were used to compare trabecular parameters between pairs of articulating distal tibia and talus. Additionally, bone volume fraction and anisotropy vector fields were mapped.

All trabecular parameters, except DA, shared a developmental trajectory within the distal tibia and talus. Both bones exhibit rapid accumulation of bone mass during the fetal period, followed by a reduction in BV/TV during the first year of life. Structural heterogeneity then increases as each bone adapts to the acquisition and maturation of the bipedal gait. Prior to the onset of the bipedal gait, it is postulated the talus is more isotropic than the tibia due to differences in ossification and vascular patterns. Once the bipedal gait has developed, the transmission of weight-bearing forces likely results in differences in DA.

Overall, this research provides insight into how trabecular bone responds to developmental and biomechanical factors during the early stages of life.

3 CORTICAL AND TRABECULAR BONE RESPONSE TO BIPEDALISM IN AN EXPERIMENTAL RAT MODEL

Campillo, America (Department of Anthropology, Pennsylvania State University) - Kuo, Sharon (Department of Biomedical Sciences, University of Minnesota Duluth; Technological Primates Research Group, Max Planck Institute for Evolutionary Anthropology) - Foster, Adam (Department of Anatomy, School of Osteopathic Medicine, Campbell University) - Ryan, Timothy (Department of Anthropology, Pennsylvania State University)

Combining cortical and trabecular bone analyses is useful to address questions regarding human evolution and behavior, specifically behaviors related to the evolution of human bipedalism. However, when using archaeological or fossil remains, it is difficult to directly relate cortical and trabecular bone structure to specific aspects of locomotion (activity level vs posture). This study provides the unique opportunity to use an experimental rodent model, which induced bipedal gait using a treadmill-mounted harness system, to assess the response of cortical and trabecular bone to locomotor and postural forces. For 12 weeks, rats walked on a treadmill with different locomotor modes and split into five groups: fully-loaded bipedal walking, partially-loaded bipedal walking, bipedal standing, quadrupedal walking, and no-exercise controls (n=70, 14/group). Cortical and trabecular bone structure was analyzed in the femur using μ CT. Cortical bone cross sectional geometric properties were quantified at 10% increments along the diaphysis and trabecular bone volume fraction (BV/TV), degree of anisotropy (DA), and trabecular thickness (Tb.Th.) were quantified in the distal femur. Femoral cortical bone exhibits an anteroposterior flattening in the distal diaphysis of the activity groups compared to the control group ($p < 0.05$). Trabecular BV/TV is higher in the medial condyle of the bipedal groups than the quadrupedal and control groups, suggesting skeletal adaptation to bipedal gait. The quadrupedal group has higher DA throughout the epiphysis compared to the bipedal and control groups, suggesting less variability in locomotor posture. Bipedal groups have higher Tb.Th. than the quadrupedal and control groups. This study shows that cortical bone is sensitive to changes in locomotor activity level, while trabecular bone is responsive to changes in both locomotor posture and activity. These results are useful for reconstructing locomotor and postural behavior in skeletal remains.

4 RE-STRUCTURING OF CORTICAL BONE AT THE FEMORAL MIDSECTION DURING EARLY GROWTH AND LOCOMOTOR DEVELOPMENT OF CHILDREN

Swan, Karen (Natural History Museum, London) - Ives, Rachel (Natural History Museum, London) - Humphrey, Louise (Natural History Museum, London)

Cortical bone structure changes throughout life via the modelling and remodelling of the internal and external bone surfaces. The amount and distribution of cortical bone within a diaphyseal cross-section is influenced by mechanical, hormonal and metabolic factors and can have important mechanical implications in terms of bone strength and resistance to bending. As humans are an altricial species, they are not born with the ability to locomote independently. The first few years are characterized by a wide range of postural and locomotor behaviours, which vary in the nature and frequency of loading, and coincide with increasing body mass and skeletal growth. Here we use micro-CT scanning to visualize and quantify changes in cortical bone structure at the femoral midsection and consider the mechanical implications of these changes during this highly complex and physiologically demanding life stage. The sample comprised femora from 89 individuals from 18th and 19th century London aged from birth to 8.5 years. Femora were virtually aligned to a common anatomical plane and cross-sections were extracted at 50% of maximum intermetaphyseal length. Outlines of the sub-periosteal and endocortical border were used to measure cross-sectional shape, relative medullary area and intracortical porosity area. Relative medullary area decreased markedly between birth and 6 months representing a displacement of bone material further from the neutral axis, which creates a more mechanically advantageous structure by the time infants typically start loading their lower limbs. A transient period of increased intracortical porosity was documented during infancy which was shown to rebound at about the age of 1 year when children typically start to walk independently. Cross-sectional shape varied throughout the age range reflecting the direction of loading associated with gait maturation. These results collectively illustrate a complex interplay of mechanical and non-mechanical factors during growth during and the transition to bipedality.

5 DEVELOPING DURING THE YOUNGER DRYAS: INSIGHTS INTO GROWTH PATTERNS OF HUNTER-GATHERERS FROM ITALY

Ciappi, Giorgia (Department of Biology, University of Florence, Italy) - Dori, Irene (Department of Biology, University of Florence, Italy) - Mori, Tommaso (Department of Biology, University of Florence, Italy; University Museum System, Anthropology and Ethnology Section, University of Florence, Italy) - Riga, Alessandro (Department of Biology, University of Florence, Italy) - Moggi-Cecchi, Jacopo (Department of Biology, University of Florence, Italy) - Sparacello, Vitale (Department of Life and Environmental Sciences, University of Cagliari, Italy)

European foragers during the cold phases of the Late Pleistocene had to adapt, biologically and culturally, to rapid climatic fluctuations and harsh environmental conditions. Upper Palaeolithic (UP) people show low genetic diversity and

small effective population sizes, and their funerary behaviours seem to emphasize “exceptional people and exceptional events”, such as disease (often congenital) and violent deaths, which could jeopardize the survival of small bands of hunter-gatherers. The apparent selection of the individuals to whom the formal burial was accorded renders difficult the reconstruction of the general health status and developmental patterns of UP people. The Epigravettian skeletal series from Arene Candide (Liguria, Italy ca. 12,900-11,600 cal BP), with more than 20 individuals of various age classes buried during the Younger Dryas cooling event, provides a unique opportunity to explore the interplay between environmental conditions and cultural factors on the paleobiology of the last Pleistocene foragers.

Individuals undergoing developmental stress due to environmental insults exhibit slower rates of growth, delayed maturation, prolonged growth, and smaller final adult size. We compared the proportion of mean adult size (femoral bone length and cross-sectional total area at midshaft) attained during growth in seven children/adolescents from Arene Candide, whose age-at-death was independently estimated from dental development. These growth patterns were compared with a modern healthy sample (the Denver Growth Study). All children from Arene Candide between the age of 1 and 6 years show growth faltering when compared to the DGS, suggesting long-term developmental disturbances. Interestingly, this is not the case in two UP and one Mesolithic children dating from before and after the Younger Dryas cooling event (Grotte des Enfants, Grotta della Madonna). Although funerary selection may have still played a significant role, growth patterns at Arene Candide may have been affected by worsening environmental conditions during the last glacial peak.

6 BONE MICROARCHITECTURAL ANALYSIS: A WAY TO DETECT, UNDERSTAND AND DIAGNOSE PATHOLOGICAL CONDITIONS AND PROCESSES IN CHILDREN

Colombo, Antony (Ecole Pratique des Hautes Etudes - Paris Sciences et Lettres Université; UMR 6034 Archéosciences Bordeaux)

Micro-computed tomography (μ CT) is a non-invasive and non-destructive X-rays imaging technique which allows to analyze bones internal structures at a microscopic scale, without altering their integrity. Since the 2000's, this method has become an increasingly important technique for investigating bone structures, as well as for cortical bone as for trabecular bone, and morphology in biological anthropology. Nevertheless, μ CT imaging is still relatively less widely used in paleopathology.

However, it offers a unique opportunity to reconstitute, at the microarchitectural level, the pathological processes which are at the origin of macroscopic lesions, and thus provides an important aid to retrospective diagnosis.

After a brief summary of the utilization of μ CT imaging in paleopathology through the specialized scientific literature, this paper will present the benefits of the μ CT imaging for paleopathology through different examples of non-specific bone lesions, of deficiency and congenital diseases. For these paleopathological examples, μ CT analysis has been proven decisive in analyzing lesions, reconstructing processes, understanding their impact on normal development, and helping for the diagnosis of osteoarchaeological cases.

7 AGE EFFECT ON TRABECULAR BONE ORGANISATION UNDER INSERTIONAL CORTICAL OSTEOLYSIS(ICO): 3D- μ CT ANALYSIS OF ENTHESIAL CHANGES ON A JUVENILE OSTEOARCHAEOLOGICAL SAMPLE

Navarre, Gwladys (Ecole Pratique des Hautes Etudes; UMR 6034 Archéosciences-Bordeaux) - Dutailly, Bruno (UMR 6034 Archéosciences-Bordeaux; UMR 5199 PACEA) - Vanderesse, Nicolas (UMR 5199 PACEA) - Dutour, Olivier (Ecole Pratique des Hautes Etudes; UMR 6034 Archéosciences-Bordeaux) - Coqueugnot, H el ene (UMR 6034 Arch eosciences-Bordeaux; Ecole Pratique des Hautes Etudes)

Entheses occupy an important place among the skeletal markers of activity and have been explored since the 1980s using clinical, radiological, histological and osteo-archaeological methods. Some studies have highlighted age-related variations in the morphology of enthesial changes: localised cortical osteolysis is frequently observed in immature skeletons, in contrast to the osteophytic processes seen in adults. The development of μ CT and 3D imaging methods is leading to a better understanding of these mechanisms.

Recent studies have focused on the microarchitecture of growing bone, both normal and pathological, in order to better understand its variability. For entheses, the microarchitecture of the cortical canal network was studied to determine the structural variability between normal insertion, metabolic enthesopathy and mechanical enthesopathy, but the trabecular structure under enthesial changes has not yet been studied in detail.

Insertional cortical osteolysis (ICO) is interpreted either as normal developmental variations or as the result of bio-mechanical overload on a growing skeleton. This hypothesis should be confirmed by the orientation of the trabecular bone under the enthesis, which should follow the main direction of biomechanical forces, in accordance with Wolff's law. This pattern needs to be clarified using 3D reconstructions of μ CT analyses of these ICOs.

Our preliminary results of 3D- μ CT analyses of the humeral insertion of the latissimus dorsi muscle on osteoarchaeological samples from immature individuals of various ages with ICO have shown that the main orientation of the trabecular bone varies with individual's age. Although this observation needs to be confirmed on a larger sample, it suggests that the architectural organisation of the trabecular system, in response to the same biomechanical overload, also depends on the period of growth during which the activity occurs. These first results confirm the need to take age into account when studying skeletal markers of activity in bioarchaeology.

8 MICROARCHITECTURAL DEVELOPMENTAL PATHWAY OF THE CRIBRA ORBITALIA: MICRO-CT ASSESSMENT OF CRIBROUS CHANGES

Mikasinovic, Veda (Centre of Bone Biology, Faculty of Medicine, Belgrade) - Djukic, Ksenija (Centre of Bone Biology, Faculty of Medicine, Belgrade) - Djuric, Marija (Centre of Bone Biology, Faculty of Medicine, Belgrade)

The investigation of cribrous changes, particularly cribra orbitalia (CO), on skeletal remains has become a prominent subject in bioanthropology, primarily due to the high prevalence of these conditions and the diverse interpretations they offer. CO is manifested by varying degrees of porosity, thinning of the outer surface of the orbital roof, and the expansion of intertrabecular spaces, resulting from bone marrow hyperplasia. While previous research has mainly focused on macroscopic observation, evaluating CO severity and the degree of activity/healing in CO lesions, the microstructural changes induced by CO remain less understood. This study employs micro-CT analysis to elucidate cortical and trabecular microstructural changes in non-adults under 15 years of age, both with and without macroscopic traces of CO (n=28), in relation to the severity of the CO lesion, using a widely employed 5-grade scoring system. Micro-CT analysis was used to examine cortical and trabecular microstructural changes in relation to the severity of CO lesions.

Our analysis demonstrated that microstructural changes in both bone compartments are equally influenced by the presence of CO and the severity of CO lesions. However, intergrade comparisons indicated that, for most analyzed microstructural variables, there was no statistical significance between closely related types of lesions, including the comparison of the control group with the mildest form of CO lesions. Despite this, our study suggests that microstructural changes do not progress linearly. Instead, a trend of linear progression was observed from the mildest to the most advanced forms of CO.

In conclusion, our study contributes to the understanding of microstructural changes induced by CO in non-adults.

1008 FOOD PROCESSING AND COOKING PRACTICES IN EUROPE, NORTH AFRICA, AND WESTERN ASIA (NEOLITHIC TO IRON AGE)

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Dalla Longa, Elisa (CNR-ISPC (Institute of Heritage Science - National Research Council of Italy)) - Alberti, Maria Emanuela (SAGAS Department, University of Florence) - Arena, Alberta (Österreichische Akademie der Wissenschaften / Österreichisches Archäologisches Institut) - Tsafou, Evgenia (Université catholique de Louvain)

Session format: Regular session

Studies on ancient diet and cooking practices are well developed and help shedding light on various aspects of social and daily past life. Some issues are still to be unraveled in the scholarly debate: to overcome regional and chronological specialisations; to reach a broader perspective; to discern the resources used in food preparation and the use of food-related tools. Additionally, there is an increasing need for the examination of resources as salt, milk, products derived from cereals and legumes, dairy products, natural sweeteners, and other minor ingredients. With this session we aim at bringing together researchers working on different areas and periods, to share methods, contextual and diachronic perspectives, artifacts' studies, including pottery typology and technology, use of tools, petrographic and residue analysis, as well as experimental activities, actual recipes, and palaeobiological dataset.

We intend to: examine the material characteristics of artefacts, structures, and facilities for food production; uncover the tools employed in the creation of food products; explore the allocation of settlement areas for food production and the production itself. The extensive chronological and geographical scope considered allows us to elucidate how these practices change in tandem with economic and social structures from the Neolithic to the Iron Age. Methodologically, we will adopt a multidisciplinary approach, welcoming contributions in archaeology, archaeometry, functional analysis (use-wear and residue), experimental archaeology, and ethnographic comparison.

The session is the output of the collaboration of two research groups: Elisa Dalla Longa (CNR-ISPC, IT), Alberta Arena (OeAI, AT), Florencia Inés Debandi (DISCI-UniBO, IT), Juan Francisco Gibaja (IMF-CSIC, ES), Giulio Lucarini (CNR-ISPC, IT); and Emanuela Alberti (SAGAS-UniFI, IT), Bartłomiej Lis (IAEPAN, PL), Jerolyn Morrison (Baylor University, US), Evgenia Tsafou (AEGIS Group, UC-Louvain, BE).

According to the number of participants and the themes of the presented papers, the session may be subdivided into distinct sub-sessions.

ABSTRACTS

1 BUILDING A STRONG REFERENTIAL: WHEN ETHNOGRAPHIC WORK CAN HELP ARCHAEOLOGICAL INVESTIGATIONS ON FOOD PROCESSING

Malergue, Alex (Université Côte d'Azur; CEPAM) - Martignac, Louise (Université Côte d'Azur) - Drieu, Léa (CNRS; CEPAM) - Buvry, Océane (IPMC) - Debayle, Delphine (IPMC) - Sall, Moustapha (Université Cheikh Anta Diop) - Mayor, Anne (Université de Genève) - Regert, Martine (CNRS; CEPAM)

Studying subsistence strategies, management of plant and animal resources, and food practices of populations of the past is one of the focal points of archaeology, and mobilizes a number of specialties. While archaeozoology and archaeobotany, when ecofacts are preserved, can provide many answers to our first two questions, access to a detailed understanding of culinary practices and the processes involved in preparing some foods remains limited.

Technical and methodological advances in the analysis of organic residues have made it possible to characterize certain molecules preserved in the walls of archaeological ceramic vessels, and thus identifying processed or preserved food. To go further in the identification of animal and vegetal species prepared in ceramics, we offer to present a methodology based on the analysis of specific components, triacylglycerols, using gas chromatography and liquid chromatography-tandem mass spectrometry.

Those molecules are present in all living organisms, with specific distributions, and thus present a strong chemotaxonomic potential. In this communication we detail the construction of a new modern referential, which relies in particular on fresh material, ethnographic and experimental collections collected in Senegal, as part of the Sinergia project "Foodways in West Africa".

These methodological developments, on a class of biomarkers present in several archeological contexts where organic matter is well preserved (lacustrine sites, acid soils in Corsica and on the Atlantic coast in particular), already show interesting results when it comes to distinguish between species used as dairy livestock (cow, sheep), or to discriminate between vegetable oils (linseed, olive oil, shea butter...). Reaching this level of resolution of the data is necessary to better understand food systems and the function of pottery, and triacylglycerols might be the way to obtain better results than previous methods, especially to approach the different steps of some "chaînes opératoires".

2 TAPHONOMIC PROCESSES AND DEGRADATION OF PLANT-BASED FOODS IN CERAMIC VESSELS: BIOMOLECULAR DATA FROM A LONG-TERM BURYING EXPERIMENT

Morandi, Lionello (University of Pisa, Department of Civilisations and Forms of Knowledge; Eberhard Karls University Tübingen, Archaeometry Research Group) - Mattonai, Marco (University of Pisa, Department of Chemistry and Industrial Chemistry) - Amicone, Silvia (Eberhard Karls University Tübingen, Archaeometry Research Group; University College London, Institute of Archaeology) - Ribechini, Erika (University of Pisa, Department of Chemistry and Industrial Chemistry)

Fruits and vegetables have played a crucial role in the subsistence and diet of several prehistoric and early urbanised societies. Their dietary intake is usually investigated through stable isotope analysis of human bioapatite and collagen and through archaeobotanical techniques looking at macro and micro-remains from archaeological sites. Aside from plant oils and waxes, organic residue studies have mostly focused on lipids of animal origin, due to their better preservation and diagnosticity. Therefore, the contribution of plant components to the overall diet remains a challenging point to address. With this paper we present results from a long-term field and laboratory experiment aimed to assess the visibility of plant-derived compounds from sherds deposited within a series of modern soils, mimicking various depositional environments. A selection of fruits and vegetables native to an area extending from Africa to the Near and Far East have been subjected to different cooking preparations. Ceramic fragments of known porosity, purposely produced for the experiment, have been placed in contact with processed and unprocessed plant material and buried within the topsoil of sites displaying a range of pH values, to simulate the taphonomic processes at work in archaeological sediments. The degradation over time and the potential for preservation in the pottery of plant proxies such as polyphenols and pigments were then investigated using analytical methods based on chromatography and mass spectrometry.

3 NEOLITHIC FOODWAYS: TOWARDS AN UNDERSTANDING OF FOOD-PROCESSING ACTIVITIES AT NEOLITHIC ÇATALHÖYÜK

Tsoraki, Christina (University of Leicester)

Ethno-archaeological research invariably shows that food-processing activities are dynamic social practices that contribute to the socialisation of small-scale communities and enable the construction of different social categories. Stone implements such as querns are an essential element in the processing of cereals, legumes and other plants that were consumed during different types of meals and forms of social engagement (routinized meals/feasts). Hence, while grinding tools played an important role in the workings of the subsistence economy, they were also instrumental for the social reproduction of prehistoric communities.

The Neolithic site of Çatalhöyük in Türkiye, dating from 7100 BCE to 5900 BCE, provides an excellent case-study to explore these themes in depth. Capitalising on the rich dataset of grinding tools, ecofacts and well-preserved architecture this paper provides insight into the organisation of food processing activities during the long habitation of the site that spans over 1500 years. Questions about food production, and the location and scale of plant processing activities at Çatalhöyük have been approached through the technological, contextual and microwear analyses of the grinding implements. Microwear analysis confirms their use for plant-processing activities including the processing of cereals, and legumes, while morphometrical analysis of the grinding tools and their use-faces provides insights into processing techniques and motor habits adopted during the execution of grinding tasks. Spatial and contextual analysis demonstrates that grinding activities had strong associations with houses and their occupants and were among the practices that structured the perception and use of physical and social space.

By applying an integrated approach on the study of grinding tools from different contexts this paper considers the social and material histories of food activities at a single settlement.

4 UNVEILING THE 'FOCACCIA' CULINARY TRADITION IN LATE-NEOLITHIC UPPER MESOPOTAMIA THROUGH EXPERIMENTAL, USE-WEAR, PHYTOLITH, AND ORGANIC-RESIDUE ANALYSES

Taranto, Sergio (Sapienza University of Rome, LTFAPA; Autonomous University of Barcelona, Department of Prehistory) - Breu Barcons, Adrià (Autonomous University of Barcelona, Department of Prehistory; Koç University of Istanbul, College of Social Sciences and Humanities) - Portillo, Marta (Institució Milà i Fontanals (IMF) Department of Archaeology and Anthropology, Archaeology of Social Dynamics; CSIC Spanish National Research Council) - Le Miere, Marie (CNRS-Université Lyon 2, MSH Maison de l'Orient et de la Méditerranée) - Gómez Bach, Anna (Autonomous University of Barcelona, Department of Prehistory) - Molist, Miquel (Autonomous University of Barcelona, Department of Prehistory) - Lemorini, Cristina (Sapienza University of Rome, LTFAPA)

This paper presents the results of doctoral research concerning the function of a Late Neolithic Near Eastern pottery type commonly referred to as the 'husking tray.' Fragments belonging to this ceramic form have been unearthed across the Near East, spanning from the Mediterranean coast to the Iranian plateau. Our research employs an integrated approach, combining ethnographic comparisons, experimental archaeology, and analyses of use-wear, phytoliths, and organic residues, with a primary focus on shards from Southeast Turkey and Northern Syria. The study strongly suggests that these vessels could have been used as baking pans for bread-like products sometimes enriched with various ingredients such as animal fat or plant oil. Notably, we highlight the importance of integrating different types of analyses and the advances introduced in the observation of macro and micro use-wear evidence as a new methodological development for the functional study of archaeological ceramic materials. By utilizing a multi-faceted approach, we aim to provide a comprehensive understanding of the function and significance of the 'husking tray' in Late Neolithic Near Eastern societies, shedding light on their culinary practices and technological innovations in pottery usage.

5 DECIPHERING OF GRINDING-MILLING TOOLS USE: FOOD PROCESSING ACTIVITIES AT MIDDLE CHALCOLITHIC GÜVERCINKAYASI, CENTRAL ANATOLIA

Doležalová, Kristina (Institute of Archaeology of the CAS, Prague; Institute of Classical Archaeology, Faculty of Arts, Charles University) - Řídký, Jaroslav (Institute of Archaeology of the CAS, Prague) - Pilař, Daniel (Institute of Archaeology of the CAS, Prague; Department of Archaeology, Faculty of Arts, Charles University) - Šíďová, Barbora (Institute of Archaeology of the CAS, Prague) - Gülçür, Sevil (Prehistoric Archaeology Department, Istanbul University)

Grinding-milling tools (thereafter GMT) are key to understanding everyday activities such as processing and preparation of food. The shape of GMTs is influenced by many circumstances, such as the availability and characteristics of raw materials, human skills, traditions, and cross-community interactions. Multiple shapes lead to the same functional use and, on the other hand, the same shape can have many functional applications. The use-wear analysis combined with the experimental program can shed light on the use of these tools. This paper presents the study of GMT assem-

blage from Middle Chalcolithic site Güvercinkayası located in Central Anatolia. Twenty artefacts were submitted to use-wear analysis to better understand the kinematics and life of the tools and how function is connected to shape or raw material and whether the tools were used at all. The study is complemented by the experimental program designed to investigate the development of wear from the grinding of various plant substances on rhyolite GMT replicas. The study has yielded several important findings related to the function and kinematics of food processing tools and has shed new light on their users. Most tools show similar use-wear traces that can be associated with the grinding of organic plant matter materials, such as cereals or legumes. Thanks to the pattern of use-wear traces, it was possible to determine the position of the user relative to the grinding stones. Some of the tools have proved to be unused. Furthermore, the analysis helped to distinguish mortars from containers.

6 FIRE INSTALLATIONS ON THE ANATOLIAN PENINSULA: A COMPARATIVE ANALYSIS FROM THE LATE BRONZE AGE TO THE IRON AGE

Casucci, Giacomo (Università degli Studi di Pavia)

The paper presents a comparative analysis of fire installations that have been discovered in Anatolia over a century of excavations. The aim is to provide a new perspective on the continuities and/or discontinuities that characterise a crucial moment in the history of the ancient Eastern Mediterranean, specifically the Late Bronze Age and the first half of the Iron Age (ca. 1650-650 BCE). Ovens, hearths, and andirons emerge as the basic categories of fire installations discernible across archaeological strata spanning the 2nd and 1st millennia BCE at various Anatolian sites. Discussing typology, construction methods, materials and location of the various fire installations, this study attempts to delineate their functions at different stages of culinary preparation (i.e. boiling, stewing, roasting, and baking) with the aim of highlighting possible continuities and discontinuities in space and time. Interpretations will be based on the analysis of artefacts found in the contexts of the fire installations (e.g. cooking pots and trays), together with considerations of the archaeobotanical and archaeozoological remains associated with them. In addition, insights from quantitative analyses, experimental archaeology, and observations derived from ethnoarchaeological observations will be incorporated for a comprehensive exploration.

7 BREWING STONES. THE LITHIC PRODUCTION FROM THE PREDYNASTIC BREWERY OF HELIOPOLIS, EGYPT

Lucarini, Giulio (National Research Council of Italy, Institute of Heritage Science, CNR-ISPC, Rome) - Manclosi, Francesca (National Research Council of Italy, Institute of Heritage Science, CNR-ISPC, Rome) - Lombardi, Lorena (University of Pisa; National Research Council of Italy, Institute of Heritage Science, CNR-ISPC, Rome) - Marsilio, Adelaide (University of Bari Aldo Moro; National Research Council of Italy, Institute of Heritage Science, CNR-ISPC, Rome) - Ugliano, Federica (Museo Egizio, Turin; National Research Council of Italy, Institute of Heritage Science, CNR-ISPC, Rome)

Located on the outskirts of Cairo, the site of Heliopolis stands as one of Ancient Egypt's most significant cities. Inhabited since the middle of the 4th millennium BC during the Predynastic period, the site has yielded crucial archaeological evidence spanning a considerable timeframe.

In 2019, the Egyptian-German Heliopolis Project team uncovered a diverse set of structures and artifacts in Area 251, including a rich lithic assemblage, mud-brick walls, and pits, connected to brewery installations. These findings offer new insights into the poorly understood Predynastic occupation of the site.

While Predynastic breweries are known from various sites in Upper and Lower Egypt, existing data primarily focus on the installations and residue analyses from associated ceramic vessels. However, there remains a knowledge gap concerning other materials linked to these production facilities.

This paper presents preliminary results on the chipped-stone artefacts associated with the brewery, aiming not only to suggest functional correlations between flint tool-types and beer production, but also to provide deeper insights into the organization of specialized activities and the socio-economic structure of Predynastic communities in the Delta during the 4th millennium BC.

Considering the location and dimensions of the brewery, beer production stands out as one of the earliest specialized activities exceeding domestic needs. The paper delves into the integration of the lithic system within this framework by comparing chipped-stone assemblages from both the brewery and the broader Predynastic settlement, including the artefacts of the rich Schiaparelli's collection from the Museo Egizio of Turin. Our aim is to observe differences and analogies in flint tool production and use.

8 THE NEOLITHIC SETTLEMENT OF LA MARMOTTA (ITALY): A WINDOW INTO THE PAST TO LEARN ABOUT WORKING TOOLS AND FOOD PROCESSING

Gibaja, Juan (IMF-CSIC) - Mineo, Mario (Museo delle Civiltà) - Mazucco, Niccolò (Pisa University) - Caruso, Laura (Conicet) - Morell, Berta (IMF-CSIC) - Remolins, Gerard (Regirarocs, S.L.) - Arranz, Amaia (Basque Country University) - Rottoli, Mauro (Laboratorio di Archeobiologia dei Musei Civici di Como) - Portillo, Marta (IMF-CSIC) - Hamon, Caroline (CNRS)

Lake settlements often preserve many archaeological remains that are not commonly found in most terrestrial sites. The lack of oxygen allows for the preservation, particularly of resources and tools made from biotic materials such as wood, plants, etc. This is the case of the Early Neolithic settlement of La Marmotta, discovered under the waters of Lago di Bracciano in the late 80s.

As one of the Neolithic sites of reference for understanding those societies and their expansion throughout the Mediterranean, it has been understudied in recent years. However, this has changed in recent years thanks to the collaboration between the Museo delle Civiltà in Rome and the Spanish National Research Council, supported by the project PID2020-112513RB-I00/AEI/10.13039/501100011033 funded by the State Research Agency of the Spanish Ministry of Science, Innovation and Universities. An international working group has been set up to reconstruct much of the archaeological information deposited in the museum and to address many aspects related to the economic and social organization of those early Neolithic groups that occupied central Italy in the mid-6th millennium BC.

In this paper we present a generic representation of the hundreds of lithic and wooden instruments related to the collection and production of resources, such as bows, sickles, spoons, axes, etc. Likewise, we show the link between these instruments and the documented food remains in the work processes related to their processing and cooking. If the fauna remains provide us with relevant information on livestock, hunting and gathering practices, the remains of thousands of seeds and processed foods such as bread, show us the variety of domesticated and wild plant species consumed and the processing of certain goods.

9 ATYPICAL FOOD CHOICES AND STRATEGIES OF A MID NEOLITHIC COMMUNITY AT MOLINO CASAROTTO (NE ITALY)

Breglia, Francesco (Department of Geosciences, University of Padua, Italy) - Prillo, Vito (Department of Cultural Heritage, University of Padua, Italy) - Dal Corso, Marta (Department of Geosciences, University of Padua, Italy) - D'Aquino, Silvia (Department of Cultural Heritage, University of Padua, Italy) - Polisca, Federico (Department of Cultural Heritage, University of Padua, Italy) - Piazzalunga, Giorgio (Department of Cultural Heritage, University of Padua, Italy) - Salzani, Paola (Soprintendenza Archeologia, Belle Arti e Paesaggio per le Province di Verona, Rovigo e Vicenza) - Nicosia, Cristiano (Department of Geosciences, University of Padua, Italy)

Molino Casarotto is a Middle Neolithic site of the Squared-Mouthed Pottery Culture located near the ancient shore of Lake Fimon (Vicenza province, northern Italy). Archaeological excavations took place in 1969-1972, and in 2022 a new archaeological campaign, included in the ERC CoG GEODAP project, yielded brand new data from a single structure, especially thanks to a systematic sampling for bioarchaeological studies. The food choices and strategies of this community clearly differ from what is commonly understood as a salient feature of Neolithic societies, i.e. the productive economy based on cereal agriculture and livestock.

The results on food remains revealed a peculiar connection with the lacustrine environment. The most abundant plant remains are water chestnuts (*Trapa natans*), which were collected from the lake, roasted and possibly ground to produce dough products. These fruits may have been consumed as a staple food, effectively replacing cereals, which are very scarce at the site. Other wild fruits, such as acorns and hazelnuts, were also gathered. Numerous fish vertebrae and cranial remains have also been recovered, mainly referring to pike (*Esox lucius*), of medium to large size, and secondly to tench (*Tinca tinca*). Abundant fragmented mollusc shells (especially of the genus *Unio*) further support the site's reliance on freshwater resources. Notably, some fish and mollusc remains exhibit distinctive burning traces, possibly suggesting culinary practices applied to species that often remain elusive in archaeological contexts.

The economic relevance of foraging and fishing at Molino Casarotto could constitute a cultural identity factor, as well as an economic strategy linked to the adaptation to available environmental resources. This is especially the case shall a seasonal occupation at Molino Casarotto be demonstrated. Both these aspects will be discussed in this paper, also in light of the comparison with archaeobotanical and archaeozoological data available from other Lake Fimon Neolithic settlements.

10 CHARACTERIZATION OF COOKING STONES FROM EARLY NEOLITHIC SITES IN SOUTHWESTERN EUROPE

Cantelli, Margherita (Institute of Environmental Science and Technology (ICTA-UAB) and Department of Prehistory, Universitat Autònoma de Barcelona, Bellaterra, Spain; Université Côte d'Azur, CNRS, CEPAM, Nice, France) - Terradas, Xavier (Spanish National Research Council (IMF-CSIC), Barcelona, Spain) - Binder, Didier (Université Côte d'Azur, CNRS, CEPAM, Nice, France) - Regert, Martine (Université Côte d'Azur, CNRS, CEPAM, Nice, France) - Colonese, André Carlo (Institute of Environmental Science and Technology (ICTA-UAB) and Department of Prehistory, Universitat Autònoma de Barcelona, Bellaterra, Spain)

Cooking stones, while commonly found in prehistoric sites, remain one of the least studied elements of the archaeological record, of which little is known about their geographic, chronological and cultural distribution, as well as of its competitive advantage in relation to other food processing techniques. Their investigation has the potential to expand our knowledge of prehistoric culinary practices, the evolution of cuisine, and its impact on the overall diet and economies in the past. To address this research gap, we conducted an analysis of archaeological stones that were potentially used for the preparation of foodstuffs and other products in Early Neolithic sites in southwestern Europe. Specifically, these stones (sandstones, marl and limestones) were recovered from contexts with evidence of culinary activities at the Neolithic sites of La Draga (Spain) and Abri Pendimoun (France). Using a combination of morphological techniques (3D and photogrammetry), visual inspection (evaluation of fractures, shape and colour), and organic residue analysis (ORA) of extracted lipids (via GC, GCMS and GCCIRMS), we identified distinctive classes of stones with differing thermal alteration patterns and isotope compositions. The results suggest that some stones may have been used for processing or manipulating plants at La Draga, while others were also likely involved in meat and dairy use at Abri Pendimoun. This study sheds light not only on the varied prehistoric culinary techniques, but also highlights the significance of these practices in shaping past diets and economies. Moving forward, further investigation into cooking stones promises to provide invaluable insights into the evolution of cuisine and its enduring impact on human societies throughout history.

11 AEGEAN COOKING SETS AND COOKING TRADITIONS - A COMBINED COMPARATIVE APPROACH

Tsafou, Evgenia (Université Catholique de Louvain) - Alberti, Emanuela (SAGAS Department, University of Florence) - Lis, Bartłomiej (Institute of Archaeology and Ethnology, Polish Academy of Sciences) - Morrison, Jerolyn (Baylor University, US)

New excavations and approaches to ceramic studies in the recent decades have led to the development of the research on cooking vessels, highlighting their role in defining of the socio-cultural aspects of ancient societies. Studies of the Aegean Bronze Age produced new datasets of cooking vessels, leading to new definitions of their typochronological development, the composition of cooking sets, the use of different types of cooking vessels, as well as to new interpretations of the social aspects of cooking practices.

This paper presents the results of studies on cooking pottery from the Aegean during the Middle and Late Bronze Age (1700-1050 BCE). These results highlight recent insights into possible cooking practices in the Aegean based on the study of individual cooking pots as well as the reconstruction of entire cooking sets. The case studies discussed include cooking pottery from selected sites in Minoan Crete and the Mycenaean Mainland. This wide range of case studies provides a distinct opportunity to compare Aegean cooking traditions across time and space in order to better understand their development and mutual relationships, which could be the result of a multitude of factors, including social tradition, technological constraints, political developments and human mobility.

12 COMBINING USE-WEAR ANALYSIS AND EXPERIMENTAL ARCHAEOLOGY. A FOCUS ON COOKING WARES FROM MIDDLE BRONZE AGE PHAISTOS (CRETE)

Sandei, Irene (Ca' Foscari University of Venice)

Recent studies on cooking ceramics explore the function and use of these materials employing two innovative approaches: use-wear analyses and experimental archaeology. Use-wear analysis examines surface alterations related to the use of the vessel to evaluate its interaction with heat sources, as well as the cooking method and consistency of the content. Combined with experimental archaeology, the replication of a vessel provides valuable insights into the manufacture and function of its elements, thereby enhancing the understanding of the performance of cooking activities.

Given limited knowledge of cooking ceramics during the Middle Bronze Age in Crete, the typological study and new edition of Protopalatial (Middle Minoan IB-Middle Minoan IIB, XIX - XVII cent. BC) cooking wares from Minoan Phaistos aims to address this gap. This is particularly significant, considering that the Protopalatial period is a crucial moment in Crete, owing to the foundation and development of the First Palaces. Additionally, Phaistos is the sole site on the island preserving structures and ceramic contexts associated with in situ Protopalatial materials. Through

comprehensive functional and use-wear analyses combined with an experimental archaeology approach, the study targets the understanding of the use of these specific cooking ceramics.

The Protopalatial cooking wares from Phaistos include several cooking vessels meant for cooking and heating food, such as cooking jars, tripod cooking pots and tripod cooking dishes, and cooking dishes. A distinct type, the side-spouted jar, has been identified, yet its use and function remain uncertain. Widely attested at Phaistos and in several Minoan sites in Southern Crete, the side-spouted jar has been interpreted as a typical shape for this area. The experimental production of this unique vessel, combined with a typological and use-wear analyses, aims to better understand the use and function of the type, as well as the actions and ergonomics of its components.

13 COOKING AND CONSUMPTION PRACTICES ON MINOAN PEAK SANCTUARIES: THE CASE OF PANTOTINO KORYFI AND STAVROMENOS ANATOLI, IERAPETRA, SOUTHEASTERN CRETE

Kalara, Antigoni (National and Kapodistrian University of Athens)

The present study explores the role of practices related to the preparation and consumption of food in the ritual context of Minoan peak sanctuaries during the Protopalatial and Neopalatial period. The examination is based on the pottery evidence from two neighboring sites, Pantotinou Koryfi (Middle Minoan IB – II) and Stavromenos Anatoli (Middle Minoan III – Late Minoan I), in the region of Ierapetra, southeastern Crete. Despite pottery being the most abundant category of finds and a significant source of information about the nature of activities at these sites, the majority of the excavated ceramic material remains inadequately studied and unpublished. The author's study of the ceramic assemblages of Pantotinou Koryfi and Stavromenos indicates that the preparation and/or massive consumption of food and drink held a central role in the cult from the Protopalatial to the Neopalatial period. The analysis brought to light a diverse range of fabrics and shapes associated with at least four different pottery production centers in eastern Crete. Both assemblages display a wide variety in the size and capacity of vessels, reflecting the coexistence of various cooking habits, recipes, and consumption practices at these rural shrines. Contextual analysis of the pottery further elucidates the extent and spatial distribution of these practices at each sanctuary. In conclusion, a comparison of the results from Pantotinou Koryfi and Stavromenos suggests a shift in ritual practices during the Neopalatial period, with a notable emphasis on cooking practices performed by communities from a broader region, along the south and north coast of the Isthmus of Ierapetra.

14 USING MINOAN COOKING POTS: EXPERIMENTAL COOKING & ORGANIC RESIDUE ANALYSIS

Morrison, Jerolyn (Baylor University) - Tsafou, Evgenia (Sissi Excavations)

Developing typologies and chronologies of cooking pots in the Aegean Bronze Age has been practiced since the mid to late 1900's in Greece. This critical work on domestic wares has generated dialogue in the scholarship that defines cooking sets and at least one component of the Minoan kitchen. Beyond this descriptive work, cooking experiments using ceramic pots has been conducted to demonstrate basic culinary techniques. Yet despite this knowledge, there are practical aspects of the cooking process that remain unclear for each individual Aegean Bronze Age type of cooking vessel. Perhaps uncertainty and lack of clarity should be expected when exploring the "how to's" of ancient domestic tasks as a modern individual; as domestic jobs today and in the past can be accomplished many ways. Even with accepting this reality there are observational tools that can be applied to ancient domestic studies that allow scholars to explore how daily tasks were performed. By taking a multidisciplinary approach, this paper sheds light on the different ways that Minoan cooking vessels were used to prepare food. This approach includes the analytical methods of experimental archaeological and functional analysis (with a combination of use wear analysis and organic residue analysis). In particular, cooking practices related to cooking dishes from three case studies settlements, Mochlos, Sissi and Malia, and from contemporary archaeological contexts of the Neopalatial period will be presented.

15 COMPARING BRONZE AGE COOKING SETS FROM CRETE AND SARDINIA

Alberti, Maria Emanuela (Università degli Studi di Firenze, Dipartimento SAGAS)

Bronze Age Mediterranean interconnections are a well-investigated topic. Besides written sources, the archaeological indicators for connectivity that are usually considered are imported raw materials or products, prestige objects, technologies, and relevant local imitations/interpretations.

It is now time to bring the discussion further, to examine the sphere related to habits and practices, especially concerning daily life. Were there some shared habits, some Mediterranean ways of life, diffused widely among common people of the various Mediterranean regions? This is a subject requiring a highly diversified archaeological background, calling specialists of the various areas to cooperation. However, a first and limited attempt is proposed here, just to throw a stone into the pond.

The average cooking sets from Bronze Age Crete and Sardinia show striking similarities: both are composed of tripod cooking pots of various sizes and wide shallow cooking dish (tegami in Italian), some with rounded bottom (coppe di cottura), and cooking plates (piastre di cottura). This set is attested in both islands from early times (e.g. the evidence

from EBA Myrtos Phournou Koriphi in Crete, and Copper Age Selargius Su Coddu in Sardinia) to the late phases of the LBA (e.g. LM IIIB/C Phaistos in Crete and RBA Nuraghe Arrubiu in Sardinia). It implies that boiling, stewing, roasting, baking, frying, etc. were performed in similar ways consistently during centuries. The presence of large shallow cooking dishes is especially noteworthy, pointing to the possible use of flat bread/loaf in both areas. This is also attested in Anatolia.

It seems then that a Mediterranean shared culture was not only made of worked ivories, transported terebinth and ingots, travelling metallurgical skills, but also of more mundane and common elements, such as cooking and eating.

This parallel is proposed to foster the discussion, with the hope to have more food for thoughts during the session.

16 EXPLORING THE TECHNOLOGICAL AND FUNCTIONAL FEATURES OF VESSELS WITH INTERNAL HANDLES IN THE BRONZE AGE VILLAGE OF MURSIA, PANTELLERIA

Debandi, Florencia (University of Bologna) - Magri, Alessandra (ISPC-CNR - Roma)

This paper aims to investigate the use of vessels with internal handles from the Bronze Age settlement of Mursia on Pantelleria island (1800-1450 BC). These ceramic vessels, similar to baking trays, are characterized by large and shallow basins equipped with two opposite handles on the inside surface, placed just below the rim. The rim is often offset, dipping down and forming a broad spout. The bottom is flat and usually thinner than the walls.

The specific configuration of these basins provides an opportunity to undertake a thorough functional investigation, looking for similar specimens in Sicily and in the broader Mediterranean context and highlighting the need to map their distribution. The methodological approach involves the description of the morphological, technological, and functional attributes (clay fabric; surface treatment; types of handles; refractoriness; use-wear traces), including macroscopic analyses, experimental replications, and ethnographic comparisons.

As for the case study of Mursia, the handles' structure and position imply that these containers can be easily and repeatedly handled and moved. The lowered rim is suitable for pouring substances. The afore-mentioned elements and the contextual analysis, with the retrieval of these basins in association with fire installations belonging to the recent phases of the settlement (c. 1550-1450 BC), allow to hypothesize these objects were involved in activities related to fire, used as cooking or heating devices.

In order to better assess the role of these vessels, a protocol for their experimental reproduction has been developed, following the models attested at Mursia and testing the hypothesized operating modes and uses.

These specialized containers identify culturally significant objects introduced by the people of Mursia in their daily cooking practices during the last phases of the settlement and represent highly diagnostic elements for a deeper understanding of Bronze Age culinary traditions, from both a technological and cultural perspective.

17 MULTIPLE PERSPECTIVES ON CULINARY TRADITIONS IN 2ND MILLENNIUM BCE NORTHERN PO PLAIN

Dalla Longa, Elisa (CNR-ISPC (Institute of Heritage Science - National Research Council of Italy)) - Dal Corso, Marta (Department of Geosciences, University of Padua, Italy) - Rottoli, Mauro (Laboratorio di Archeobiologia dei Musei Civici di Como, Italy) - Manfrin, Maria Sofia (PrEcLab – Laboratorio di Preistoria, Protostoria ed Ecologia Preistorica del Dipartimento di Beni Culturali e Ambientali – Università degli Studi di Milano, Italy) - Fapanni, Francesca (PrEcLab – Laboratorio di Preistoria, Protostoria ed Ecologia Preistorica del Dipartimento di Beni Culturali e Ambientali – Università degli Studi di Milano, Italy) - Varalli, Alessandra (CNRS, Aix Marseille Univ, Minist Culture, LAMPEA, UMR 7269, France; CASEs Research Group (Culture, Archaeology and Socio-Ecological Dynamics), Barcelona, Spain) - Nicosia, Cristiano (Department of Geosciences, University of Padua, Italy)

What is currently known about subsistence, diet, and food processing in the Northern Po Plain during the 2nd millennium BCE? To what extent are different proxies analysed collectively in the current published literature? How can data obtained from diverse proxies be most effectively integrated? How can research in this field be advanced through the integrated analysis of multiple datasets? This contribution aims to address these questions by proposing a two-step research path. Taking the Northern Po Plain in the 2nd millennium BCE as a case-study, our first goal is to provide a comprehensive review of published data on the following proxies: 1) food-related objects; 2) structures and facilities associated with food processing; 3) archaeobotanical datasets on edible plants; 4) zooarchaeological datasets on edible faunal resources; 5) isotopic data obtained from human and animal remains. As a second step, we propose an integrated analysis of the mentioned datasets in the case-study region, aiming to understand if a specific characteristic or change detected in one of the explored fields has implications in one or more of the others. For example, is there a correlation between the introduction of a new crop and the material culture? Does the succession in archaeological cultural aspects manifest in changes in the type of diet? The goal of this research is to develop a method for gaining a deeper understanding of this crucial part of human history, which we believe can only be understood through the integration of knowledge. This will not only contribute to establishing a common ground that will

refine the interpretation of archaeological contexts in field research, but also lead to the formulation of new research questions that expand our knowledge of the lives of people in the past. This work is in collaboration with the ERC CoG project GEODAP (Geoarchaeology of Daily Practices).

18 AN HOLISTIC APPROACH TO THE STUDY OF DIETARY PRACTICES AT THE BRONZE AGE SITE OF PEÑALOSA (BAÑOS DELA ENCINA, SPAIN)

Tinoco Domínguez, Lucía (University of Granada) - Contreras Cortés, Francisco (University of Granada) - Moreno García, Marta (Institute of History, CCHS, CSIC) - García Martínez, Victoria (University of Granada) - Alarcón García, Eva (University of Granada)

The main goal of this research is to study the dietary practices of the inhabitants from the Bronze Age settlement of Peñalosa (Baños de la Encina, Jaén, Spain) in a diachronic and synchronic perspective using an holistic approach. Firstly, the archaeozoological analysis helps to assess the role that meat played on the social and historical development of this Argaric society (2200 – 1550 cal BC) of the Upper Guadalquivir.

Therefore, the remains of all medium and large-sized mammal are analysed with the aim to identify potential preferences based on taxa, sex and age of these animals. Likewise, the taphonomic study, specifically the analysis of cut-marks and burned marks, throws some light on different processing and cooking techniques including the occurrence of specialised butchers in the settlement.

The data collected is understood not only in its temporal context and in a microspatial level, but also in relation to other archaeological materials such as ceramic vessels. Pottery morphology together with the identification of certain anatomical parts allow us to gain some knowledge on the different cooking techniques used. Moreover, organic residue analysis identifies animal products consumed or selected for other uses. Finally, stable isotopic studies on faunal remains are compared with those carried out on human bones and botanical macro remains and phytolith analysis from mills provide additional data to understand on food activities.

19 THE ROLE OF PLANT SUBSTANCES IN THE ANCIENT DIET OF CORSICAN PROTOHISTORIC SETTLEMENTS: A BIOMOLECULAR APPROACH APPLIED TO CERAMICS

Turini, Maïlys (Université Côte d'Azur, CNRS, CEPAM) - Drieu, Léa (Université Côte d'Azur, CNRS, CEPAM) - Malergue, Alex (Université Côte d'Azur, CNRS, CEPAM) - Mazuy, Arnaud (Université Côte d'Azur, CNRS, CEPAM) - Buvry, Océane (IPMC) - Debayle, Delphine (IPMC) - Paolini-Saez, Héléne (Laboratoire Régional de l'Archéologie) - Peche-Quilichini, Kewin (Collectivité de Corse) - Perrin, Thomas (Université de Toulouse Jean Jaurès, CNRS, TRACES) - Regert, Martine (Université Côte d'Azur, CNRS, CEPAM)

Recent organic residue analyses of samples relating to the food content of pottery and residues from the soil have demonstrated the excellent preservation of organic matter in South of Corsica (France). The Mediterranean area is known for its poor conservation of lipids, however, these large-scale studies have highlighted the diversity of natural substances exploited on the island during the First Iron Age, which may have resulted from artisanal practices and/or cooking activities (animal fats, plant oils and waxes). The subsistence economy of Corsican societies seems to be based on an agro-pastoral system and the collection of wild resources.

In this presentation, we will explore the foods that were stored, processed and consumed in pottery during the Bronze Age and Iron Age on the island, with a focus on the plant part of the diet. At some sites, vessels containing edible plants probably used in culinary activities have been found in significant proportions, an unusual result compared to data published in the literature, where animal fats are ubiquitous. We will present the range of foods consumed in protohistoric Corsica, especially plant foods, using conventional solvent extraction and gas chromatography-mass spectrometry. Some plant resources such as olive oil, wild fruits, vines are poorly preserved, we will carry out lipidomic analyses of well-preserved triacylglycerols (together with extraction analysis of short-chain fruit acids).

The foods identified by organic residue analysis in pottery will be compared with archaeobotanical data to investigate procurement and dietary practices related to plant foods, in particular questions related to the domestication of plant species such as the olive tree and the grapevine.

20 RITUAL LIBATION VESSELS BETWEEN TRANSDANUBE, AUSTRIA AND NORTHERN ITALY IN THE BRONZE AGE AND EARLY IRON AGE

Jankovits, Katalin (Pázmány P. Catholic University) - Dalla Longa, Elisa (Institute of Heritage Science, CNR of Italy) - Arena, Alberta (Österreichische Akademie der Wissenschaften, Archäologisches Institut)

In scientific literature, various vessel typologies, such as askos, rhytons, and boot-shaped or animal-shaped vessels, have frequently been associated with ritual and religious practices of libation in pre-protohistorical times. Recently, the interpretation of some of these shapes as libation vessels has been substantiated through organic residue analysis,

exemplified by the discovery of animal hemoglobin traces in an askos from the Middle Bronze Age of Hungary, and by technological insights, such as the functional study of holes on boot-shaped vases.

This contribution aims to analyze several pottery shapes well-known in the Bronze Age Transdanube region, drawing comparisons with similar artifacts found in Austrian and Northern Italian contexts during the 2nd millennium BCE and the early 1st millennium BCE. By identifying specimens in the three analyzed regions and focusing on archaeological contexts, our objective is to determine whether shared religious/ritual practices can be discerned across the entire area during a specific chronological phase or if an origin-and-diffusion pattern can be assumed for certain vessel shapes.

Taking boot-shaped vessels as an illustrative example, we will draw a general overview of their chronological and geographical distribution. These vessels make their initial appearance in the Danube region during the Tumulus period and continue to be in use for an extended period. Notably, 22 such vessels were discovered in 19 burials of the Urnfield Culture Budapest-Békásmegyer cemetery. Boot-shaped vessels are also documented in Austria (12th-9th century BCE) and Northern Italy (9th-8th century BCE and later Iron Age occurrences). Are there discernible connections between these pots with different chronological and geographical distribution? Is any change or continuity in use or context of discovery traceable? How can these considerations help scholars to deal with the complexity of Bronze Age and Early Iron Age societies of the involved areas?

21 FOOD PRACTICES IN LATE BRONZE AND EARLY IRON AGE IN KARST (WESTERN SLOVENIA) - VISIBLE VS. UNVISIBLE REMAINS

Vinazza, Manca (Department of Archaeology, University of Ljubljana) - Potočnik, Doris (Jozef Stefan Institute) - Ogrinc, Nives (Jozef Stefan Institute) - Tolar, Tjaša (Institute of Archaeology ZRC SAZU) - Toškan, Borut (Institute of Archaeology ZRC SAZU) - Rogan Šmuc, Nastja (Department of Geology (OG), Faculty of Natural Sciences and Engineering (NTF).)

The transitional period from the Late Bronze to the Early Iron Age marked a highly dynamic period, which is evident in the archaeological material from Karst. Only in recent years have we uncovered archaeological data that shed light on past dietary practices. Through archaeological excavations conducted at two hillforts in the Karst, Tabor near Vrabče and Štanjel, dating from the Late Bronze to the Early Iron Age, we have unearthed ceramic artifacts, alongside significant archaeobotanical and archaeozoological remains. The relatively well-preserved stratigraphic context, complemented by absolute dates, enables the identification of dynamics during this time.

A typo-chronological analysis on the ceramic assemblage has unveiled the emergence of new ceramic forms, with a predominant presence of forms associated with hearth activities. These transformations align with changes in food preparation patterns, evident in both archaeozoological and archaeobotanical remains. The study is upgraded by mineralogical-petrographic analyses of the specific ceramic forms. Additionally, organic residue analysis on ceramics contributes to the identification of practices such as maceration and fermentation. The identified practices reflect the integration of Karst hillforts into a broader geographical context, extending westwards into the region of northern Italy and eastwards into central and eastern Slovenia. Nevertheless, alterations in fundamental subsistence patterns suggest a concurrent changes in social organization, characterized by smaller social units during the Early Iron Age.

22 THE USE OF MODULAR OVENS IN IRON AGE HOUSEHOLDS IN THE CAPUT ADRIAE REGION

Tasca, Giovanni (Museo Civico di San Vito al Tagliamento (Pordenone-Italy); University of Padua) - Groppo, Veronica (University of Venice) - Vinazza, Manca (Department of Archaeology, University of Ljubljana, Slovenia)

Between the Late Bronze Age and the end of the Early Iron Age a distinctive type known as the modular oven was in use in northeast Italy and the region of Caput Adriae. Fragments of these ovens, referred to as “concotti”, have been identified among different archaeological sites, like Oderzo, Montebelluna, Pozzuolo del Friuli, Udine, and Most na Soči. The constituent elements of the modular oven and its dimensions only partly correspond to the model of a modular oven attested in the Iron Age across a broader area of Central Western Europe.

Analytical observations, analyses such as ceramic petrography, XRD, pXRF, and SEM-EDS, along archaeological experiments and analogies with the Western model, have enabled the reconstruction of the forming technique and the firing process. This appears to be directly related to the function of food cooking. One of the particularly characteristic element of the modular oven under discussion seems to be its versatility of use, which could have included roasting, baking bread, or cooking other foods. In this presentation, we intend to showcase and discuss the analysis performed on samples from the Early Iron Age site of Montereale Valcellina (6th-5th centuries BC).

23 CONSTRUCTING MESSAPIAN FLAVOURSCAPES: DETECTING FLAVOURFUL WILD FOOD PLANTS IN PRE-ROMAN SOUTHEAST ITALY

Morris, Marc (University College Dublin, School of Archaeology)

Archaeobotanical research focuses primarily on grains, pulses and other domesticated crops that make up the staple diet of many agricultural societies, past and present. Archaeobotanical studies have shown to be of great importance to understanding the processes of domestication, diversification and management of these crops, as well as their centrality to ancient life in terms of diet, land use and labour. Less understood are the plants that flavoured and complemented these staple foods when they were prepared into meals—herbs, spices, fruits and vegetables—and contributed both to a nutritious and satisfying diet. This is especially true in the archaeology of the Messapian culture, which inhabited the Salento peninsula (Apulia, southeast Italy) in the first millennium BC up to the Roman conquest. This paper will summarise initial findings from a brief study aimed at detecting flavourful wild food plants and their culinary applications in the Messapian archaeological record by examining archaeobotanical remains and food crusts in cooking pots, in order to gain a closer understanding of Messapian society and daily life and their interactions with the landscape.

24 SIMMERING FRUIT, BEANS, AND HONEY IN THE LAB: EXPERIMENTAL LIPID RESULTS FROM RARELY IDENTIFIED PLANT-BASED RESOURCES IN ORGANIC POTTERY RESIDUES

Vykukal, Rachel (Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg) - Gabiger, Anastasia (Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg) - Whelton, Helen (Organic Geochemistry Unit, University of Bristol) - Pitts, Martin (Classics and Ancient History, University of Exeter) - Cramp, Lucy (Department of Anthropology and Archaeology, University of Bristol) - Hammann, Simon (Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg)

Plant or plant-derived foods, like fava beans, figs, and honey, are very difficult to identify in pottery residues, due to their ephemeral nature and/or their scant lipid profile. Although it is well-established that lipids from cooked or processed foods can become trapped in the walls of clay vessels and survive for millennia, plant foods tend to be masked by fattier meat-based substances and their actual contribution to ancient diet is often ambiguous. Thus, in order to gain a more complete picture of ancient diet and culinary practices within the archaeological lipid data, it is important to explore how to identify relatively lipid-poor resources in pottery residues. We approached this issue through experimental lab-based archaeology; a series of cooking experiments were conducted to investigate eight plant or plant-based foods from the Iron Age and Roman period Britain in replica cookware. This is part of the Roman Melting Pots project, where over 900 archaeological pottery samples are currently being analyzed to explore cultural diversity and integration through culinary practices. A main aim of the experiments was to investigate potential novel biomarkers for currently underrepresented or invisible resources using two complementary high-resolution techniques, specifically liquid chromatography and gas chromatography coupled with high-resolution mass spectrometry [LC-HRMS, GC-HRMS]. We compared these to the lipid signatures of raw food extracts. Biomarker results and observations in lipid absorption behavior will be discussed, in addition to preliminary archaeological findings.

1009 BEYOND THE LENS: CONTEMPORARY METHODS AND INTERDISCIPLINARY SYNERGIES IN ARCHAEOBOTANY

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Kriti, Alexandra (Institut Català d'Arqueologia Clàssica) - Moricca, Claudia (Department of Environmental Biology, Sapienza University of Rome) - Vignola, Cristiano (Department of Environmental Biology, Sapienza University of Rome) - Andonova-Katsarski, Mila (Division of Palaeobotany and Palynology, Institute of Biodiversity and Ecosystem Research, Bulgarian Academy of Sciences) - Audiard, Benjamin (Institut des Sciences Analytiques, UMR 5280 CNRS, Université Claude Bernard; Laboratoire de Géographie Physique : Environnements Quaternaires et Actuels, UMR 8591 CNRS - Universités Paris 1 Panthéon Sorbonne et UPEC)

Session format: Regular session

Archaeobotany, the study of plant remains from archaeological contexts, used to be exclusively performed in a lab; isolated individuals sorting out and identify seeds through a stereoscope's lens. The traditional analytical approaches to study plant macro- and micro-remains are usually focused on the reconstruction of plant exploitation, as well as past landscape and footprints of human activities.

In the last decades, innovative protocols have been developed to investigate past environmental conditions, agronomic practices, and the past exploitation of plants. Morphometry, stable isotopes and organic residues analyses, and the recovery of ancient DNA have highlighted the role(s) of plants in the daily activities of ancient communities.

The simultaneous advance of digital humanities, the spread of social media and the introduction of AI tools in various inter- or cross- disciplinary project collaborations have forced the discipline to move fast-forward.

As a result, the agency of past individuals and/or communities and their interaction(s) with plants is being re-visited by many researchers and professionals across Europe. These attempts re-frame archaeobotany as a discipline that can be conducted outside the lab and is relevant to its age and era by utilising cutting edge technology.

In this session we aim to explore contemporary methods and synergies attempting to re-visit old questions in archaeobotany with new digital tools, re-use of botanical collections, agricultural archives and/or ethnographic records, perform ambitious experiments inside and beyond the lab, and re-introduce the wider audience to ancient agriculture and cuisine through inclusive remote and/or participatory actions.

We welcome contributions from researchers and professionals associated with archaeobotany, anthropology/history of food, ethno-archaeology/botany, and experimental archaeology to share experiences illustrating how contemporary inter- and/or cross-interdisciplinary methods in archaeobotanical research can bridge the gap between archaeology and the modern natural and physical sciences, as well as ordinary people of the 21st century and their past.

ABSTRACTS

1 TESTIMONIES OF RUIN. SYNERGISTIC ANALYSES OF ARCHAEOBOTANICAL REMAINS FOUND IN A POTTERY DEPOSIT IN CIEPŁE STRONGHOLD, POLAND

Nowosadzka, Ilona (University of Warsaw, Poland) - Kobjek, Weronika (University of Warsaw, Poland)

The early medieval cluster of settlements, strongholds and cemeteries in Ciepłe, Poland, has been under scrutiny of many researchers. In the most recent project we aim to thoroughly examine the Ciepłe 3 site, which is the current well-boding object of archaeologists' interest, we use Interdisciplinary research linking archaeobotanical, archaeozoological approaches and landscape archaeology to the traditional archaeological methods.

During the 2023 expedition we stumbled upon a deposition of three ceramic pots stacked inside one another in interchanging directions. On their sides there was a plurality of charred organic remains that became the main subject of our study.

Our goal to reconstruct the pots, understand their purpose and the circumstances in which they were deposited will be met by morphological, stylistic and typological, as well as the petrographic analysis of the ceramic fragments. The archaeobotanical identification of organic remains, in the context of their absolute chronology obtained from the AMS method, locations of which were measured and appraised by the RTK GPS technology, will be supplemented by the carpological analysis.

By this we hope to achieve not only the direct interpretation of this deposit, but also the fate of the stronghold as a whole. We are aware that our initial chronological assessments of Ciepłe show us a rather short span of activity. A deposit, especially such an unusual one, may shed some light on some dramatic events from the stronghold's history.

2 ETHNOLOGICAL APPROACH TO ACORN UTILIZATION IN PREHISTORY

Tang, Mengxia (Zhejiang University) - An, Ting (Zhejiang University) - An, Juhui (Zhejiang University)

Acorn remains are reported from prehistoric sites across the world. Acorn is argued to have been a significant food resource for humans in prehistory. However, relevant research is still limited and it is often challenging to recognize archaeological remains relating to acorn utilization. This research tackles the acorn processing pathway through a case study of 'mook making' in South Korea, employing semi-structured interviews and direct participant observation. The case study provides an explicit record of the acorn processing method, which consists of collecting, grinding, rinsing and filtering, starch-shell separation, boiling, solidification and serving. We draw attention to laborious nature of acorn processing and to different methods of acorn processing due to different species and culinary tradition. Particularly, the method in our case is about starch extraction, a specific form of acorn processing that might have been unique to East Asia due to culinary traditions. Additionally, the paper highlights potential archaeological and archaeobotanical markers associated with each step of the acorn-processing procedures and considers the chances of residue preservation under different conditions. These insights contribute to new perspectives on the archaeological interpretation of acorn remains.

3 LAB-INDUCED HEATING OF GREEK BARLEY (H.VULGARE) LANDRACES; A SET OF EXPERIMENTAL METHODS TO EXPLORE PAST AGRICULTURAL PRACTICES

Kriti, Alexandra (Institut Català d' Arqueologia Clàssica) - Livarda, Alexandra (Institut Català d' Arqueologia Clàssica) - Orenge, Hector (Institut Català d' Arqueologia Clàssica) - Mylonas, Ioannis (Hellenic Agricultural Organization-Dimitra, Institute of Plant Breeding and Genetic Resources) - Ninou, Elissavet (Department of Agriculture, International Hellenic University)

Experimental cultivations of 21 Greek barley (H.vulgare) landraces were conducted during the winter cultivation seasons of 2020-2022 in Themi, Thessaloniki in Greece as part of the collaboration between the Catalan Institute of Classical Archaeology/GIAP and ELGO-Demeter. The harvested grain from 3 landraces with different geographical and climatological zones' origin were chosen for further analysis.

A set of lab-induced heating experiments took place during late 2023 and early 2024 to explore -under controlled conditions, the morphological impact of heating on the surface of selected grains. Beyond the meticulous data collection that is recommended by the relevant literature, we also conducted -for the first time, extensive 3D scanning on all selected grains.

3D GMM comparable analysis on the shape of fresh and heat affected grains, combined with a new heating protocol that aims to record all laboratory-based observations, provides us with a unique insight on the effect of various heating treatments on the morphology of the grains. Additionally, each grain's morphology -either fresh or heat affected, is associated with a particular landrace and cultivation regime, opening another level of understanding of contemporary and/or ancient heat affected crops' grains.

The implementation of such a tool in archaeobotany, may provide the opportunity to further explore ancient crops regional origin and movement(s), as well as to investigate past cultivation practices in the Aegean and beyond.

4 TWO IN DISTRESS MAKES SORROW LESS: HOW SHARING FAILS CAN BRING DISCIPLINE FORWARD

Garay Palacios, Blanca (Institut Català de Paleoecologia Humana i Evolució Social (IPHES-CERCA), Zona Educativa 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili, Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Berihuete-Azorín, Marian (Universitat Autònoma de Barcelona (UAB), Departament of Prehistory, Edifici B, 08193, Bellaterra (Cerdanyola del Vallès), Spain.; Institut Català de Paleoecologia Humana i Evolució Social (IPHES-CERCA), Zona Educativa 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili, Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Expósito, Isabel (Institut Català de Paleoecologia Humana i Evolució Social (IPHES-CERCA), Zona Educativa 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili, Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.)

One of the main focuses of Archaeobotany is the study of the relationship between prehistoric groups and their environment. Through the study of plant remains we can understand how this environment was like, but also how it was used and exploited by humans. However, in some cases, recovery, processing, and identification of these archaeobotanical micro- and macro-analyses are not enough, and we need to carry out experiments and use other discipline's methodologies to interpret them.

From the more basic reference collection to the many options of charring regimes, processing techniques, or even cultivation, many different types of experiments have been carried out. The problem is that the lack of detailed protocols can make the experiment design a whole process on its own, where you must start with experimenting with different variables before getting to the point.

Moreover, almost only successful protocols are usually published, when mistakes or unsuccessful experiences are just as important, and all of them can be used as a starting point for the next experiment. In this communication, we will present some experiments, protocols, successful results, and also, failed experiments. We want to take the opportunity to encourage the scientific community to share all their results/experiments, no matter the outcome, since this may be key to building up a corpus of information and bringing forward our discipline.

5 ADAPTABILITY AND RESILIENCE: FARMING PRACTICES IN THE IRON AGE SOUTHEASTERN BALTIC

Minkevicius, Karolis (Nature Research Centre) - Kisielienė, Dalia (Nature Research Centre)

Traditionally, the period between the 1st and the 5th century AD in the Southeastern Baltic has been perceived as a time of flourishing and prosperity. The increasing access to prestigious artifacts, growing social complexity, and

changing settlement patterns are all supported by archaeological evidence. Unsurprisingly, this has resulted in an idealized image of well-established rural communities thriving on local agricultural produce.

However, recent inquiries into human-environment interactions during the Roman period have started to question such narratives. Archaeobotanical studies of charred crop assemblages from numerous sites in Lithuania, coupled with stable carbon and nitrogen isotope analysis of the main cereal taxa, have indicated significant regional variation, different farming strategies, landscape maintenance practices, and a range of environmental challenges. There is also evidence of varying degrees of success in agricultural activities.

This highlights the importance of applying interdisciplinary methods to geographically and archaeologically diverse datasets. Such an approach not only permits a more grounded overview but also offers more opportunities to analyze and understand settlement life-cycles on a case-by-case basis.

6 THE STUDY OF STABLE CARBON ISOTOPES ON ARCHAEOLOGICAL CHARCOALS TO RECONSTRUCT THE PALEOCLIMATE DURING LATE BRONZE AGE IN CENTRAL ITALY

Reggio, Chiara (Department of Science of Antiquities, Sapienza University of Rome, Italy; Department of Environmental Biology, Sapienza University of Rome, Italy) - Vignola, Cristiano (Department of Environmental Biology, Sapienza University of Rome, Italy) - Bettelli, Marco (National Research Council, Institute of Cultural Heritage Sciences (CNR-ISPC), Rome, Italy) - Cardarelli, Andrea (Department of Science of Antiquities, Sapienza University of Rome, Italy) - Dallai, Luigi (Department of the Earth Sciences, Sapienza University of Rome, Italy) - Di Renzoni, Andrea (National Research Council, Institute of Cultural Heritage Sciences (CNR-ISPC), Rome, Italy) - Masi, Alessia (Department of Environmental Biology, Sapienza University of Rome, Italy) - Sadori, Laura (Department of Environmental Biology, Sapienza University of Rome, Italy)

The study of past environmental conditions for plant growth is pivotal in tracing the socio-economic evolution of ancient societies, whose developments were closely linked to plant exploitation and crop production. This is especially true for the Bronze Age, one of the most controversial periods in Prehistory when important cultural changes occurred in association with strong climatic fluctuations and drought crises. From an archaeobotanical perspective, the application of stable isotope analysis to plant remains offers the possibility to reconstruct the palaeoenvironmental conditions in which plants grew, especially the stable carbon isotopes that record past water availability.

We present preliminary results of archaeobotanical and stable isotope analyses carried out at Monte Croce-Guardia (Arcevia, central Italy), one of the most important Late Bronze Age sites in Italy. The settlement arose in the 12th century BC, in parallel with complex changes in the settlement layout in Marche and surrounding areas (such as the collapse of Terramare in the Po Valley), and was abandoned about two centuries later, precluding the formation of the cultural entities of pre-Roman Italy.

We identified charred wood remains recovered from primary archaeological deposits, such as hearths, working surfaces, and other activity areas located on terraces connected to the settlement, covering the entire occupational sequence. Among woody taxa from different vegetation types, we selected charcoals of deciduous and evergreen *Quercus* to measure the stable carbon isotope ratio ($\delta^{13}C$). The isotopic signals provide useful information for reconstructing local precipitation patterns during the study periods. In addition, differences between the two oak species are interpreted in relation to ecological and physiological characteristics. These data will be further compared with the stable carbon isotope records of cereal remains to investigate how past climatic conditions influenced agricultural activities and, in general, social developments at Monte Croce-Guardia at the end of the Bronze Age.

7 LATE UPPER PLEISTOCENE CLIMATIC OSCILLATIONS IMPACT ON AN ENDANGERED SPECIES BASED ON GEOMETRIC MORPHOMETRY. THE CASE OF COREMA ALBUM

Martínez Varea, Carmen María (Departamento de Prehistoria, Historia Antigua y Arqueología, Universidad de Salamanca, Spain; ISEM-UMR 5554, Université de Montpellier, CNRS-IRD-EPHE, Montpellier, France) - Bouby, Laurent (ISEM-UMR 5554, Université de Montpellier, CNRS-IRD-EPHE, Montpellier, France) - Ivorra, Sarah (ISEM-UMR 5554, Université de Montpellier, CNRS-IRD-EPHE, Montpellier, France) - Audiard, Benjamin (Institut des Sciences Analytiques, UMR 5280 CNRS, Université Claude Bernard Lyon 1, France; Departament de Prehistòria, Arqueologia i Història Antiga, Universitat de València, Spain) - Badal García, Ernestina (Departament de Prehistòria, Arqueologia i Història Antiga, Universitat de València, Spain)

The Palaeolithic sequence of Cova de les Cendres (Alicante, Spain) has provided a rich archaeobotanical assemblage. In the carpological assemblage, *Corema album* (Portuguese crowberry) outstands. Its remains are abundant during the Gravettian, scarce during the Solutrean and completely absent during the Magdalenian (Martínez-Varea et al., 2019). The current main population of this taxon is limited to the Atlantic coast of the Iberian Peninsula, and just 11 plants survive on the Mediterranean coast, hence its Pleistocene evolution in this region is of great interest for its conservation.

We hypothesise that Late Upper Pleistocene climatic oscillations, especially during the Last Glacial Maximum (c.27 – 19 ka cal BP), profoundly impacted the ancient Mediterranean populations of *Corema album*, affecting their fructification. Geometric morphometry of the archaeological pyrenes has been performed to detect changes that could be related to these fluctuations. This methodological approach has been applied to cultivated taxa (e.g. grape, legumes) to identify species and infra-specific morphotypes or to shed light on the domestication process (Bouby et al., 2021; Tarongi et al., 2024). Their application to wild species is not frequent.

The results of the geometric morphometry analysis are correlated to other palaeoclimatic proxies available in Cova de les Cendres, such as the isotopic analysis ($\delta^{13}C$) of *Juniperus* sp. wood charcoal and the anthracological analysis.

8 A MULTI ANALYTIC APPROACH TO DISCRIMINATE VARIETIES OF TRITICUM DURUM CARYOPSES IN ARCHAEOLOGICAL CONTEXT

Stella, Matilde (Laboratorio di Archeobotanica e Paleoecologia, Dipartimento di Beni culturali, Università del Salento) - Grasso, Anna Maria (Laboratorio di Archeobotanica e Paleoecologia, Dipartimento di Beni culturali, Università del Salento) - Capone, Martina (Laboratorio di Archeobotanica e Paleoecologia, Dipartimento di Beni culturali, Università del Salento) - Laghetti, Gaetano (IBBR-CNR Institute of Biosciences and BioResources) - Blangiforti, Sebastiano (Stazione Consorziale Sperimentale di Granicoltura per la Sicilia) - Fanizzi, Francesco Paolo (Laboratorio di Chimica generale e inorganica, Dipartimento di Scienze e Tecnologie Biologiche ed Ambientali, Università del Salento) - De Benedetto, Giuseppe Egidio (Laboratorio di Spettrometria di massa analitica ed isotopica, Dipartimento di Beni culturali, Università del Salento) - Fiorentino, Girolamo (Laboratorio di Archeobotanica e Paleoecologia, Dipartimento di Beni culturali, Università del Salento)

During the archeological research you can come across in granaries, in storage or transport containers where it is common to find large numbers of caryopses. Distinguishing varietal groups of species among fossil plants is still one of most difficult tasks in archaeobotany. Succeeding in this, however, means being able to reconstruct trade dynamics, to interpretate past agricultural management and to identify selection strategies. The aim of this work is testing new investigation methods capable of distinguishing wheat caryopses (in particular *Triticum durum*) from a varietal point of view. The experimentation was carried out on fresh and charred samples of modern durum wheat varieties (commercial and local), applying multiple analytical methods (biometry, morphometry, NMR, IRMS). The study focuses on the numerical, dimensional and morphological caryopses variations in relation to their ear position. Some varieties were also subjected to metabolomic and $\delta^{13}C$ e $\delta^{15}N$ isotopic analyses with the aim of discriminating the varieties from each other by edaphic and environmental factors.

9 ADDING ANCIENT DNA TO MULTI-PROXY ARCHAEOBOTANICAL STUDIES OF COPROLITES YIELDS FURTHER INSIGHT INTO NEOLITHIC DIETARY DIVERSITY

de Groot, Arjen (Wageningen UR; Utrecht University) - Kubiak-Martens, Lucy (BIAX Consult) - Özdoğan, Kadir (Utrecht University; Wageningen UR) - Plets, Gertjan (Utrecht University) - Huisman, Hans (University of Groningen; Cultural Heritage Agency of the Netherlands)

Archaeobotanical study of fossilized faeces, i.e. coprolites, provides invaluable information on the diet and health of ancient societies, as it offers direct evidence of their food consumption. This holds particular significance for studies of Neolithic cultures in NW-Europe, where local populations are thought to have shifted from hunter-gathering to agricultural practices, leading to changes in dietary patterns for both humans and their domesticated animals. A recent multi-disciplinary project addressed these inquiries by analyzing a set of coprolites from the mid-Neolithic Swifterbant Culture (4300–4000 cal BC) in The Netherlands, employing a variety of methods, including micro-CT and SEM analysis, along with the microscopic study of phytoliths, pollen and other microfossils. This revealed a unique picture of a ‘community diet’ in which both humans and domestic animals combined ‘wild’ natural food sources with new agricultural products. However, this research was confined to identifiable dietary components retrieved from the coprolite samples. In this paper, we present new insights gained through the re-examination of the same coprolites using ancient environmental DNA analyses. This new technique allows the extraction of DNA from environmental samples, either within or outside organic remains. We show how these new data partially confirmed existing results,

but also added new information on dietary composition and provided new evidence on the identity of the coprolite producers.

10 HARNESSING INNOVATION TO DECODE THE SECRETS OF PALEOLITHIC GROUND STONE TOOLS

Sorrentino, Giusi (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Cagnato, Clarissa (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Longo, Laura (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Semenzin, Elena (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Marcomini, Antonio (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Porpora, Francesca (Department of Chemistry “Ugo Schiff” - University of Florence) - Carretti, Emiliano (Department of Chemistry “Ugo Schiff” - University of Florence) - Badetti, Elena (Department of Environmental Sciences, Informatics and Statistics - Ca' Foscari University of Venice) - Dei, Luigi (Department of Chemistry “Ugo Schiff” - University of Florence)

Starch, a reserve of polysaccharides stored in plant amyloplasts, was discovered alongside use-wear traces on ground stone tools (GSTs) dating back to the Late Pleistocene: Marine Isotopic Stage 3 (MIS 3, 60–25 ka BP). This suggests that *Homo sapiens* (HS) was actively processing various plant organs during its diffusion into Eurasia. Traditional starch grain analysis involves morphometric characterization using optical microscopy with bright and polarized light, typically after sampling from archaeological artifacts using wet or dry extraction procedures.

We propose an integrated methodology for the characterization of starch grains adhering to the archaeological GST working areas, testing different approaches for their extraction. Indeed, traditional removal procedures can interfere with their physico-chemical characterization and impact on the GST use-wear trace analysis. Additionally, proper characterization necessitates a comparative reference collection. Our approach relies on the combination of traditional morphological characterization merged with cutting-edge chemoprofiling techniques enhanced by innovative extraction procedures. Moreover, it has allowed further analysis including the comparison with a tailored reference collection of starch granules from plants potentially available during MIS 3 in the relevant geographical area(s). Through this multidisciplinary approach we aim to enhance the narrative on the exploitation of available resources by hominins thriving in a given territory.

Ministero dell'Università e della Ricerca (MUR) of Italy, Project PRIN 2022 2022XX8BRT PNRR, “SMarT4Bio-ArCH”, CUP Master B53DZ3014020006, financed by the European Union – Next Generation EU, is gratefully acknowledged for financial support.

11 BRIDGING DIMENSIONS IN CEREAL PHYTOLITH IDENTIFICATION: A COMPARATIVE STUDY OF 2D AND 3D MORPHOMETRIC DATA

Hermans, Rosalie (Archaeology, Environmental Changes and Geo-Chemistry (AMGC), Vrije Universiteit Brussel, Pleinlaan 2, Brussels 1050, Belgium.) - Li, Mao (Donald Danforth Plant Science Center, Olivette, MO 63132, USA) - Brightly, William (Department of Plant and Animal Sciences, University of Sheffield, Sheffield S10 2TN, UK) - Gallaher, Timothy (Bishop Museum, Honolulu, HI 96817, USA) - Strömberg, Caroline (Department of Biology, University of Washington, Seattle, WA 98195, USA) - Nys, Karin (Archaeology, Environmental Changes and Geo-Chemistry (AMGC), Vrije Universiteit Brussel, Pleinlaan 2, Brussels 1050, Belgium.) - Snoeck, Christophe (Archaeology, Environmental Changes and Geo-Chemistry (AMGC), Vrije Universiteit Brussel, Pleinlaan 2, Brussels 1050, Belgium.)

This research focuses on silica plant microfossils, called phytoliths, and particularly, a specific phytolith morphotype that is frequently encountered in grass inflorescences, ELONGATE DENDRITIC. In archaeological contexts, this morphotype is often ascribed to the presence of cereals. However, its formation in both cereals (wheat, rye, oats, and barley) and wild grasses forms a challenge in making definitive taxonomic distinctions, casting uncertainty on their reliability as a cereal marker. The primary objective is to explore the capability of ELONGATE DENDRITIC to differentiate between cereals and wild grasses, and to determine the extent to which they can be used to accurately classify cereals at genus and species level.

Last year, we prepared a substantial phytolith reference dataset of cereals and wild grasses that we used to develop a 3-D phytolith model dataset (n = 1.850 surface meshes). This dataset was created using confocal microscopy and Imaris image processing software. This year, we introduce a 2D phytolith image dataset (n = 9.100 phytolith outlines), generated using conventional light microscopy and ImageJ processing software. This dataset aims to provide a more accessible and cost-effective alternative for the identification of cereal phytoliths.

To quantify the morphology of the phytoliths, morphometric features were extracted from the 3D surface meshes and the 2D phytolith outlines. This included both traditional shape and size features and features deriving from Persistent Homology, which is a technique from algebraic topology used to quantify complex shapes.

By using a set of machine learning models, the study evaluates the performance of both datasets to identify phytoliths at species and genus level. The study also reflects on the usage of Persistent Homology as a quantification technique in phytolith research. Our goal is to ascertain the optimal balance between taxonomical precision and practical applicability in the identification of cereal phytoliths in archaeobotanical studies.

12 CHARCOAL CHEMISTRY: UNCOVERING THE MOLECULAR MYSTERIES. FROM PRESERVATION TO THE IDENTIFICATION OF TAPHONOMIC PROCESSES IN ARCHAEOLOGICAL CONTEXTS

Roversi, Deborah (University of York; French National Centre for Scientific Research | CNRS · CEPAM UMR 7264) - Théry-Parisot, Isabelle (French National Centre for Scientific Research | CNRS · CEPAM UMR 7264) - Penkman, Kirsty (University of York) - High, Kirsty (University of York)

Compared with archaeological wood and other organic remains, charred materials survive in various climatic conditions. As such, they represent the main source of organic materials in some archaeological contexts, thus playing an important role in the study of past human practices. Although for decades charcoal has been considered an inert material, some preservation issues related to the deposition environment have been highlighted (Ascough et al. 2010; Braadbaart et al. 2009). These observations raise important questions about the representativeness and potential biases of anthracological assemblages in assessing past vegetation and fuel management.

To further investigate the changes induced by the charring and the depositional process, and how this could be affecting the preservation of the charcoal itself, a comprehensive investigation into the molecular structure of charred materials is needed.

This study applies Fourier transform infrared spectroscopy (FT-IR) analysis to give an insight into how different processes commonly encountered in an archaeological context (e.g fungal attack, different soil acidity, freeze cycles, etc.) can affect the molecular structure, and therefore the level of preservation and accurate representation of charcoal in archaeological assemblages.

The primary goal is to establish a correlation between the chemical composition of charcoal and specific anatomical indicators, such as vitrified charcoal, whose origins remain ambiguously identified. As part of this research, experimental and archaeological charcoal, subjected to different processes and/or conditions, has been characterised through Fourier transform infrared spectroscopy (FT-IR) enabling the identification of chemical group differences and comparisons of structural changes. Although infrared spectroscopy has been utilised in industrial charcoal characterization, its application to archaeology is hindered by diverse research approaches and material complexities. The purpose of this presentation is to address these challenges and explore the potential of adapting this technique for anthracological studies.

1011 INVESTIGATION OF NEOLITHIC LITHIC TECHNOLOGY AND EXPERIMENTATION: AN APPROACH TO TECHNICAL VARIABILITY

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Minguell López, Arnau (PhD student in Universitat Autònoma de Barcelona) - Ménager, Cécile (Dr and associate researcher to Archéorient (UMR 5133 - CNRS)) - Defranould, Elsa (UMR7264-CEPAM) - Terradas, Xavier (Spanish National Research Council (CSIC-IMF, Barcelona)) - Palomo, Antoni (Universitat Autònoma de Barcelona)

Session format: Regular session

Knapped lithic productions and experimentation emerge as crucial elements in the research of the Neolithic period, playing a fundamental role in understanding the technological complexities of this era. This session delves into a meticulous analysis of lithic technology, exploring the evolution of tools throughout the historical development from early Neolithic communities to the emergence of the first metals.

We examine how the tradition, cultural progression, and technological advancements of Neolithic communities are reflected in lithic assemblages. Special attention is given to experimental methodologies that shed light on the manufacturing and use of these productions, providing a detailed insight into the skills and techniques employed.

This session calls for contributions addressing archaeological, experimental, and analytical studies related to lithic technology in Neolithic contexts. The goal is to enrich the understanding of this crucial phase in human history, fostering interdisciplinary dialogue, experimental reconstructions, and technological analyses.

The diversity of perspectives will allow for a comprehensive overview of the significance of lithic knapped productions in the daily life, economic activities, and cultural practices of Neolithic communities. By exploring the intersection between the materiality of lithic tools and the human experience, this session aims to deepen our understanding of lithic productions in Neolithic societies.

ABSTRACTS

1 RAW MATERIALS, WORK TOOLS, AND PRODUCTION PROCESSES IN THE EARLY NEOLITHIC OF CORO TRASITO (TELLA.SIN, HUESCA)

Clemente-Conte, Ignacio (CSIC-IMF) - Hansen, Jakob (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Rey Lanaspá, Javier (Dpto. de Presidencia, Interior y Cultura. Diputación General de Aragón.) - Sierra Saiz-Aja, Alejandro (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Saña Seguí, María (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Gassiot Ballbè, Ermengol (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Díaz Bonilla, Sara (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Barba Pérez, Marcos (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Mazzucco, Niccolò (Dipartimento di Civilizzazione e Forme del Sapere, Universidad de Pisa)

The tools of the Early Neolithic period in the Coro Trasito cave, on the southern slope of the Central Pyrenees, are diverse and were crafted from different raw materials. Thus, lithic instruments are recorded in various materials such as chert from different sources, quartzite, fibrolite, granite, sandstone, hornfels, and limestone. Depending on the instrument to be manufactured and the work to be done, a specific lithic raw material is chosen, which due to its physical characteristics will be more precise or effective for carrying a specific productive task. In the same way, instruments made from other non-lithic raw materials are used, such as bones from both domestic and hunted animals, deer antler, tusks or teeth from animals, and shells from marine mollusks. It is also noteworthy the use of ceramic fragments as tools or spatulas, as well as the presence of materials such as leather, vegetable fiber, and bundles of grass for the treatment of ceramic surfaces during their manufacture.

We present the results of the traceological analyses of all these materials, grouping the instruments according to the productive activity in which they intervened. In this way, we have been able to record the different instruments that were used in the same productive process. Thus, we have registered instruments used for the production of lithic products, others for hunting and meat processing, for working animal hide, the instrumental set for ceramic production, those used for the production of vegetable fibers and the weaving in basketry, instruments involved in agriculture or the processing of agricultural products, and the working of wood and/or hard animal materials.

2 TECHNO-MORPHOLOGICAL ANALYSIS OF THE LITHIC INDUSTRY OF THE ANCIENT NEOLITHIC IN THE CENTRAL SOUTHERN CENTRAL PYRENEES

Barba Pérez, Marcos (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Clemente-Conte, Ignacio J. (CSIC-IMF (Institució Milà i Fontanals)) - Gassiot Ballbè, Ermengol (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Mazzucco, Niccolò (Dipartimento di Civilizzazione e Forme del Sapere, Universidad de Pisa)

The study of human occupation of these areas of southern Europe has experienced very important development in recent decades, with a high volume of unpublished data, relevant innovations within archeology and an increase in interdisciplinary work. This increase in data is also reflected in a greater number of lithic assemblages from a larger number of excavated sites.

This presentation outlines a brief synthesis of recent information that will focus primarily on the techno-morphological study of the lithic materials from three upland sites in the southern central Pyrenees, the rockshelter: Abric de Obagues de Ratera, Cova del Sardo de Boí and Abric del Portarró. All of them are located in the Aiguestortes i Estany de Sant Maurici National Park, at altitudes between 1800 and 2320 m. asl. The excavations carried out at the different sites have documented large archaeological sequences, with various phases of occupation during the Neolithic. The analysis of the lithic material has made it possible to explain the technological strategies involved in the places under study and to delimit the existence of different production trajectories of the raw materials present in the archaeological record, characterizing the lithic technology of the different places and identifying the technical development and technological changes produced related to the Neolithic and recent prehistory in the Pyrenees. We understand these lithic remains as social products, the result of the collective work of women and men who inhabited the past, being a reflection of the modes of production developed in certain prehistoric and historical periods. Thus, their study allows us helps to know the economic, social and technical practices of human communities, the dynamics of management and exploitation of the environment and the characterization of the evolutions and breaks of technical traditions.

3 LITHIC PRODUCTION ON THE LATE NEOLITHIC SITE OF VINČA-BELO BRDO (SERBIA)

Radinovic, Mihailo (University of Belgrade)

The Late Neolithic levels of Vinča-Belo Brdo site have yielded an abundance of lithic finds that were deposited during the 800 years of continuous occupation. The previous studies have reconstructed various aspects of lithic organi-

zation, but many questions still remain unanswered. Are there differences between chert and obsidian technology? What are the predominant knapping techniques and are there diachronic changes in this aspect? Are there traces of hafting? Is there any evidence for specialization in lithic production? Previous studies have provided different answers to these and other questions. In this study, I present the results of the analysis of Belo Brdo lithic material, arguing that different qualitative and quantitative approaches can be used as complementary tools in reconstructing different aspects of lithic organization. I also discuss the obtained results in the context of other relevant data about the site and the studied period, bringing new data to the study of the Late Neolithic of the Central Balkans.

4 A NEW APPROACH TO INDIRECT PERCUSSION: FROM EXPERIMENT TO ARCHAEOLOGY

Menager, Cecile (Archéorient)

This presentation shows the results of an experiment on indirect percussion carried out as part of a doctoral thesis. The aim of this project was to redefine the lithic knapping technique, which has often been superficially characterized. A 1473-flint-blade-experimental collection was made by five knappers. Two categories of indirect criteria could be observed on all of these blades: there were scars, a result of the use of the knapping technique, and morphological characters related to the shape of the core. These criteria were then classified into three groups according to their statistical frequency: symptomatic (ripples, no interrupted bulb, striking angle (between 80 and 90°), mesial and distal hackles, proximal hackles, no discontinuity under the bulb, no lip and, curved profile), less symptomatic (sinuous and straight arris, spontaneous retouching on the edges, convergent edges, trapezoidal or irregular sections, salient points of impact) and secondary (plain striking platform, quadrangular or ogival proximal part, bulb scars, butt inclination, broken blades, hinged or plunging blades, cracked butt, double bulb, a tongue fracturing and thick butt). Three variables were finally identified as playing a role in the frequency of these criteria: the type of the punch, the knapper and the striking angle. The criteria were then observed and compared on four laminar Neolithic collections from northern Greece (Dikili-Tash, Promachonas-Topolnica, Dimitra and Mikri Volvi), dated from Early to Late Neolithic. This method for detecting indirect percussion is intended to be trialed on other archaeological material in order to be further developed and have its accuracy improved.

5 PUNCHES AND BLADE PRODUCTIONS IN THE EARLY NEOLITHIC OF THE NORTH-EAST OF THE IBERIAN PENINSULA

Palomo, Antoni (Universitat Autònoma de Barcelona) - Terradas, Xavier (Spanish National Research Council (CSIC-IMF, Barcelona)) - Clemente, Ignacio (Spanish National Research Council (CSIC-IMF, Barcelona)) - Minguell, Arnau (Universitat Autònoma de Barcelona, Departament de Prehistòria) - Rosillo, Rafael (Independent researcher) - Piqué, Raquel (Universitat Autònoma de Barcelona, Departament de Prehistòria)

The determination of the knapping techniques used in the blade productions of the Early Neolithic has traditionally been a difficult question to resolve. The analysis of the technomorphological characteristics and comparisons with experimental collections has been the most common way to make inferences about the technique and tools used. The documentation of a series of deer antler points interpreted as punches at the Early Neolithic sites of La Draga (Girona, Spain) and Coves del Fem (Tarragona, Spain) has opened other approaches for the determination of knapping techniques. Our work has addressed the functional study of possible archaeological punches by comparing the use-wear of a set of experimental punches used in the replication of blade productions documented in the sites. The study enables us to propose various functional criteria to validate the determination of deer antler tools as punches.

Besides, the study has also contemplated the analysis of the archaeological collections from a technomorphological perspective and their comparison with the experimental productions carried out. This has, on the one hand, generated valuable data of technical characteristics associated with the use of indirect percussion and, on the other hand, has reinforced the general interpretation of the knapping techniques used during the Early Neolithic in the Northeast of the Iberian Peninsula.

1013 FUNERARY RITES IN EUROPEAN PREHISTORY: KNOWLEDGE TRANSFER IN A WORLD OF WORLDS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Brinkmann, Johanna (Institute of Pre- and Protohistoric Archaeology, Kiel University; Cluster of Excellence ROOTS, Kiel University) - Brunner, Mirco (Institute of Archaeological Sciences, Bern University; Oeschger Centre for Climate Change Research (OCCR), Bern University) - Gorgues, Alexis (UMR 5607 Ausonius, Université Bordeaux Montaigne) - Pape, Eleonore (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig) - Blank, Malou (Department of Historical Studies, Gothenburg University)

Session format: Regular session

Examining European Prehistory through the lens of funerary archaeology reveals overarching trends such as single or collective burials, diverse burial forms like flat graves or burial mounds, and shifts in burial practices across the continent, including transitions from inhumation to cremation. On a local scale, however, we find a mosaic of local burial rites merging into “one” big picture. Besides the spread of specific burial rites (e.g., the use of passage tombs in the Neolithic or in the Bronze and Iron Age cremation burials in metal urns), we see an adoption of ideas from distant or neighbouring regions, a resumption of earlier traditions and local innovations. Whereby the application of scientific methods like isotopes and aDNA shifts our perception and challenges established narratives (Kristiansen 2014). Here, in the spread of funerary rites a transfer of knowledge becomes visible in the material culture.

In this session we examine the spread of (specific aspects of) funerary practices and their temporal and spatial expansion across Europe exploring the concept of knowledge transfer. The term knowledge has been used in archaeology mostly intuitively (Hansen 2018) rather than systematically (Renn 2012), although different dimensions of knowledge (e.g., cosmological, political, and technological) are evident in funerary rites.

We welcome studies ranging from the Neolithic to the Iron Age which approach the topic on a Europe-wide scale as well as those who integrate local practices into a bigger picture. The session is open to theoretical contributions that conceptualize the notion of knowledge transfer in archaeology, as well as ethnological and ethno-archaeological studies and contributions from the archaeological sciences. We seek to identify visible routes of knowledge transfer and contacts as well as barriers, boundaries and fringes of knowledge. We inquire whether this concept can extend the discussion beyond terms like mobility and exchange.

ABSTRACTS

1 THE CONCEPT OF KNOWLEDGE AND KNOWLEDGE TRANSFER IN ARCHAEOLOGY

Brinkmann, Johanna (Institut fuer Ur- und Fruehgeschichte Kiel; ROOTS Cluster of Excellence)

Knowledge and the transmission of knowledge are essential components in all societies. Be it the passing on of technical knowledge, knowledge about certain kinds of craftsmanship, social and cultural norms, or traditions (like burial customs). Knowledge may be gained, accumulated, transferred or lost in various ways depending on the societal preconditions. In the discipline of archaeology, knowledge is omnipresent in a dual sense: on one side we as archaeologists try to reconstruct knowledge about past societies lost over time, on the other side knowledge was an essential element in prehistoric societies themselves. Who had access to which kind of knowledge, which knowledge was passed on, which forgotten or even obliterated? From De Long's (2004) division into human, social, cultural and structural knowledge to Renn's (2012) globalization of knowledge there are many concepts that can be adapted for archaeological research. This contribution will explore how the concept of knowledge and knowledge transfer can be utilized looking at archaeological phenomena. A special emphasis will be on the transmission of knowledge in funerary practices using two examples from the Neolithic and the Late Bronze/Early Iron Age, namely the spread of passage tombs and of cremation burials in metal urns.

2 THE MAIN ROAD TO PREHISTORY. THE EXCAVATION OF A BURIAL GROUND ADJOINING AN ANCIENT CROSSROAD

Wickberg, Ylva (Sydsvensk Arkeologi AB)

During an excavation, with the limitations that comes with contract archaeology, a previously unknown burial field was discovered. The project was conducted because of the widening of a road, located between the villages of Fjälkinge and Gualöv in southern Sweden. The burials proved to have an origin in the late Neolithic and the shift between Early and Late Bronze Age. A part of the graves showed to be a mix between the rituals of inhumation and cremation: The earliest ones included a coffin shaped pit, where the deceased and burial gifts was placed and then covered with stones. After a gap in time the burial ground was resumed, but now the deceased were cremated, and the remains, unburned gifts and a stone filling was placed in a - still human sized - pit. In the youngest tombs cremated remains were

placed, sometimes in a vessel, in small, shallow pits. We know that the same change of the burial rituals take place in very large geographical areas. How did the cultural transfer of new traditions and beliefs proceed in this area? New ideas spreading is depending on communication, trading, travelling, and thanks to recent years of interdisciplinarity and wide range of scientific analyses, the knowledge about people and goods movement in regional and interregional landscape is increasing. The location of the site is interesting considering this: Adjoining a modern crossroad, that historical maps confirm also existed AD 1684. Several known prehistorical settlements and burial sites also follow these roads, indicating its very ancient origin. The landscape in the area has been characterized by wetlands and bogs, and the topography makes the options of travelling limited. Have the now modest hillside once been a link in the chain of change?

3 MEGALITHIC GRAVE ARCHITECTURE AND MORTUARY PRACTICES IN NEOLITHIC WESTERN SWEDEN AS INDICATOR FOR KNOWLEDGE TRANSFER

Blank, Malou (University of Gothenburg) - Brinkmann, Johanna (Kiel University)

The building of megalithic graves was a widespread phenomenon in Neolithic Europe. Within the Scandinavian and Northern German Funnel beaker complex, the grave constructions and burial practices seem to follow defined patterns and rules, although regional differences occur. In Western Sweden the use of the megalithic graves within a Funnel beaker context is followed by c. 500 year hiatus, during which other burial customs prevailed. Then, in the Late Neolithic gallery graves emerged and spread over vast areas in Scandinavia. The Late Neolithic gallery graves are by many scholars considered as a reinvention of earlier megalithic traditions. The close connection between the Funnel beaker and the Late Neolithic megalithic graves is especially prominent in Western Sweden where large gallery graves, the reuse of earlier megaliths and the deposition of bones from earlier graves in gallery graves have been observed. The knowledge of megalith building was thus passed through the ancient monuments which were also used to emphasize a fictional belonging to mythological ancestors. Furthermore, political, and ideological knowledge were spread and established through the construction and use of these graves.

4 DECONSTRUCTING THE DEAD: EVIDENCE FOR POST-MORTEM BODY PROCESSING FROM MILLIN BAY LATE NEOLITHIC CAIRN, NORTHERN IRELAND

White, Lisa (Queen's University Belfast) - Megarry, Will (Queen's University Belfast) - Murphy, Eileen (Queen's University Belfast)

Ireland's position at the western-most part of Neolithic Europe proffers a unique and important reference point for understanding change during the Neolithic period. The mortuary record concerning the Late Neolithic period in Ireland (c.4000–2500 BC) evidences a variety of complex funerary practices which will have been impacted by concepts of social, cultural, and spiritual identity. One aspect of the mortuary record which connects many of the major burial complexes in Ireland, yet remains little understood, is the evidence of post-mortem body processing. Cut marks on human bone attesting to dismemberment and/or defleshing practices, have been identified at Carrowkeel Passage tomb complex, Co. Sligo (Geber et al., 2017), Carrowmore megalithic complex, Co. Sligo (Burenholt, 1998) and Millin Bay Late Neolithic cairn, Co. Down (Murphy, 2003; White et al. forthcoming). Yet, a cross-comparative analysis of how the living interacted with the dead during this rite has not been fully explored. Identifying patterns, or the lack thereof, in the post-mortem processing of the dead across the island of Ireland and comparing this to the wider British and European Neolithic context, may reveal networks and models of knowledge transfer on a local, regional and national scale. This paper presents the initial results of an ongoing study into the cut marks evidenced on skeletal human remains recovered from Millin Bay Late Neolithic cairn and discusses whether 'ritual' behaviour can be identified both within the site and on a wider scale.

5 THE MEMORIES OF THE GENERATIONS: VISIBLE ROUTES KNOWLEDGE TRANSFER

Higginbottom, Gail (El Instituto de Ciencias del Patrimonio (Incipit, CSIC))

To rephrase a conclusion by Bueno Ramírez et al. 2022, this presentation will demonstrate that the key to the construction & location of dolmens as well as their internal imagery is the ideological weight of visual expression and its connection to the way societies construct and see themselves. This is, of course, part of the feedback mechanisms between materialities upheld in phenomenological philosophy. However, whilst this paper sees megalithic art as inextricably linked to death, its relational place or association with the world of death is not constrained to the cult of the ancestors but expands to the passings and pasts of all things. This implies, too, that not only are the memories of a line of individuals encapsulated here (memories of generations, Bueno Ramírez et al. 2022: 185), but so too the 'the memories of the generations', knowledge of all things held by the society through time and is thus intricately linked to knowledge care-taking as well as knowledge transfer. Through the examination of dolmen associations and landscapes, this work will show that dolmens and the elements that make them, entail the answers to the central on-

tological question - "What is there?", thereby identifying the visible routes of knowledge transfer for both those of the past, present and continued generations and that some of these 'knowledges' were transferred around Iberia.

6 TRACING THE TRANSFORMATIVE SHIFT IN BURIAL CUSTOMS IN NORTHERN JUTLAND DURING THE EARLY CORDED WARE PERIOD

Nielsen, Simon (Vesthimmerlands Museum)

From around 2850 BCE and in the subsequent centuries, a significant cultural shift occurred on the Jutland peninsula in western Denmark, leading to the emergence of the Single Grave Culture within the broader Corded Ware (CW) complex. This transformative shift introduced a distinct set of burial customs, supplanting the funerary traditions of the preceding Funnel Beaker (TRB) period. This phenomenon mirrored a broader trend observed across Europe, where newly formed CW groups replaced existing practices. Recent revelations of steppe DNA within CW groups across Eastern, Central, and Northern Europe have reignited discussions surrounding immigration theories. The focus has shifted from questioning the arrival of new groups at the outset of the CW period to exploring the processes that unfolded locally and regionally, including migration as an integral component. In the southern areas of Jutland, these changes occurred in locations minimally influenced by interference from the existing late TRB groups. Conversely, in the northern regions, existing cemeteries exhibited spatial consistency, indicating localized integration between newly arrived groups and established communities. This is further exemplified by certain resummptions of the funerary rites in the region across the transition. This presentation, based on recent analyses, provides a nuanced exploration of these local developments. Specifically concentrating on Northern Jutland, it examines the integration of the new CW burial practices into a confined local region, shedding light on communication routes, knowledge transfer and cultural admixture during one of the most significant cultural shifts in the region.

7 EXPLORING THE SPREAD OF KNOWLEDGE IN CORDED WARE BURIAL PRACTICES - INFORMATION TRANSMISSION IN THE THIRD MILLENNIUM BCE

Helmecke, Florian (Leiden University)

With the rise of the Corded Ware phenomenon at the beginning of the third millennium BCE, the widespread sharing of novel burial practice principles marked a significant change in the cosmologies of Neolithic communities inhabiting the continent. This successful spread of an idea on how to bury (and equip) the dead was accompanied by major demographic shifts, which significantly altered the European gene pool according to recent aDNA studies. Current conceptualisations of these dynamics connect the changes in the archaeological record with an uptick in mobility and an influx of people from the steppes. Yet, the mechanisms behind the spread of the Corded Ware phenomenon remain largely unexamined. Explanation attempts either navigate along subjectively selected sites and findings from archaeogenetic and isotopic studies or only re-theorise broader archaeological trends. But while the former are only valid for specific times and places and widely ignore the entire funerary record at hand, the latter lack a systematic and methodological examination of the available burial data. The heart of the matter, however, remains unaddressed: Burials represent short-term social events in which collective behaviour synthesised into considerate actions of part-takers, some of which materialised in the archaeological record. These practices can be identified to investigate past knowledge transfer and understand how shared information on persistent burial practices emerged, disseminated and became transmitted over vast areas during the first half of the third millennium BCE. By reconstructing the degree of similarity between burials in a network approach, a probabilistic method is proposed to investigate the spread of knowledge between practitioners exchanging and adhering to information on world views and ideas.

8 BRONZE AGE BURIAL RITES AND SETTLEMENT DYNAMICS IN THE CENTRAL ALPS

Brunner, Mirco (University of Bern)

This study provides a detailed overview of the state of Bronze Age research in Switzerland between the Swiss Plateau and the Alps. During the Early Bronze Age, numerous rich Bronze Age burials occur in western Switzerland, which are often associated with the emergence of bronze metallurgy and the exploitation of local ore deposits. These graves contain grave goods and material culture, especially bronze artifacts, which have close links to trans-European forms of prestige and status expression. The development of bronze consumption during the three phases of the Bronze Age in the central Alpine region is discussed.

In the pre-phase (BzA1), 2200 to 2000 BCE, metal finds such as shovel head needles and daggers remain sparse. Only in the classic phase (BzA2) between 1900 and 1750 BCE can particularly rich graves be recognized, as in Thun-Renzenbühl. There are significantly more graves; the first hoard finds are deposited during this period. In addition, gender-specific distinctions in the burial rite become more regular and are visible in the grave furnishings. The spatial expansion and increasing density of settlements in the Alpine foothills and in the Alpine valleys indicate the importance of access to trade routes and resources. This development is supported by dendro and 14C data from lakeside and hilltop settlements. Between 1750 and 1550 BCE, gender-specific grave goods show strong contacts

with Central Europe. Although we observe increasing inequality in burial dress, the development of Alpine settlement dynamics, subsistence and metallurgy is a complex process that should not be subsumed under social evolutionist models of the development of a hierarchical society. The transference of knowledge plays a crucial role in this context. Between 2200 and 1600 BCE, burials were fairly uniform, but from 1600 to 1350 BCE, a wide variety of burial practices emerged. After 1350 BCE, cremation became the standard.

9 BURNING ISSUES... ADOPTION OF THE "NEW" BURIAL RITE IN MIDDLE BRONZE AGE IN THE AREA OF POLAND

Strózyk, Mateusz (Archaeological Museum in Poznan)

The presented paper concerns on the adoption of the cremation burial rite in the Middle Bronze Age (ca. 1600-1300 BC) and chronological dynamics of that process. In Central Europe, the role of the key substrate in the process of the transformations from inhumation to cremation was played by the local groups associated with the Tumulus Culture. The still lively traditions of inhumation under barrows often coexisted with a new type of burial in the form of cremation graves.

The research was conducted in relation to area of Western Poland. Some preliminary results of chronological analysis of materials from crucial funeral sites will be presented. The main sources for analysis will be the forms and ornamentation of metal objects, finding analogies in other areas of Europe during this period. Often the ornamentation remained the same, but the materials on which it appeared varied according to the needs of the host culture. In general, the main aim of mentioned research is to conduct a multidimensional analysis and interpretation of the genesis of the transformation process of Middle Bronze Age funeral rite in Poland. The submitted paper will seek answers to key questions about the nature of the profound burial rite change related to the appearance and development of the Tumulus Culture community.

10 DEVELOPMENTS OF THE BURIAL RITES BRONZE AGE MORAVIA, CZECH REPUBLIC

Šabatová, Klára (MUNI - Ústav archeologie a muzeologie) - Parma, David (Institute for Archaeological Heritage Brno) - Cheung, Christina (Department of Anthropology, Chinese University of Hong Kong) - Snoeck, Christophe (Vrije Universiteit Brussel)

This abstract focuses on the examination of Bronze Age burial rites in Moravia, shedding light on the transmission of knowledge and cultural customs in the Bronze Age Europe. At the beginning of this paper was an effort to understand the transition between the skeletal and cremation rite in the Middle Bronze Age more accurately. After obtaining radiocarbon data and in part strontium data, it turns out that some changes in the burial rite have the character of a long process and are very complex, but others are very fast.

Questions of changes in burial rite from skeletal cemeteries of the Early Bronze Age to small burial sites of the Middle Bronze Age will be illustrated based on radiocarbon data from various well typologically dated burials. The analysis of Urnfield cemeteries, characterized by cremation burials in urns, represent a significant funerary tradition spanning from the Bronze Age to the Iron Age. Through the lens of funerary archaeology and scientific radiocarbon and strontium data from cemetery Přáslavice and radiocarbon dates from other selected sites this study explores the temporal and spatial expansion of urn burial rites in Moravia, highlighting the interconnectedness of communities and the exchange of ideas within the region. By investigating the material culture associated with Urnfield burials, including grave goods the study aims to discern patterns of knowledge transfer and cultural interaction. This paper proposes a multi-disciplinary approach, integrating archaeological and scientific perspectives, but also shows the limits of scientific data and archaeological record. Still, we hope to elucidate the complexities of Burial rites in Moravia and their significance in the broader context of European prehistory.

11 IN THE MIDST OF CHANGE: MIDDLE BRONZE AGE CREMATION PRACTICES AND BURIAL MOUNDS OF UNTERRADLBERG, LOWER AUSTRIA

Skerjanz, Hannah (Austrian Academy of Sciences)

During the Middle Bronze Age Tumulus Culture (1600-1300/1200 BC), the predominant burial practice changed from inhumation to cremation within the time span of just 300 years, ultimately leading to uniform urnfield cemeteries in the Late Bronze Age. The construction of burial mounds is characteristic and eponymous for this culture, although mound building practices vary among regional groups. In this contribution, the site Unterradlberg in the Lower Austrian Traisen Valley serves as the basis for investigating cremation burials and mounds during the transitional period from the Middle to Late Bronze Age. Despite the challenges of poor preservation, this study entails a detailed bio-archaeological approach to the cremated remains, exploring aspects such as the identification of multiple individuals, mobility and absolute dating through osteological assessment, strontium isotope analysis and C14 analysis. In addition, the comparative archaeological evaluation of features aims to shed light on funerary behaviours such as experimenting with different ways of constructing mounds as well as entrances that grant access to the cremated re-

mains in the grave chamber. This paper aims to contribute to the overall discussion of knowledge transfer and possible belief systems during the Middle to Late Bronze Age transitional period, proposing a gradual change, adaptation and loss of certain traits that can be observed both on a regional and super-regional level.

12 RECONSTRUCTING A LATE BRONZE AGE COMMUNITY USING ARCHAEOGENETICS: THE EXAMPLE OF THE NECROPOLIS OF LOS CASTELLETTS II (MEQUINENZA, SPAIN)

Bretos, Marina (University of Zaragoza, Zaragoza, Spain) - Royo Guillén, José Ignacio (Dirección General de Cultura y Patrimonio, Gobierno de Aragón, Avenida de Ranillas, 5 D., 50018 Zaragoza, Spain) - Papac, Luka (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany) - Rohrlach, Adam B. (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; School of Mathematical Sciences, University of Adelaide, Adelaide, South Australia, Australia) - Gómez Lecumberri, Fabiola (Independent researcher) - Risch, Roberto (Department of Prehistory, Universitat Autònoma de Barcelona, Barcelona, Spain.) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany) - Picazo Millán, Jesús V. (University of Zaragoza, Zaragoza, Spain) - Haak, Wolfgang (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany) - Villalba-Mouco, Vanessa (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; Institute of Evolutionary Biology, CSIC-Universitat Pompeu Fabra, Barcelona, Spain)

The genetic makeup of the prehistoric European populations has been shaped by key demographic events, one being the genetic influx of Pontic-Caspian steppe pastoralists from 3000 BCE to 2000 BCE. However, throughout the Bronze Age (BA, ~2,200 - 800 cal BCE), diverse cultural groups emerged and disseminated throughout the continent, phenomena explained by culture-historical archaeology through diffusionism and/or migrations. The Late Bronze Age (LBA) in Europe (~1,300-800 cal BCE) was predominantly marked by the appearance of the so-called Urnfield culture, which extended westwards, from Central Europe to the Northeast of the Iberian Peninsula (~1,250 cal BCE), and established cremation as main burial practices. Regional disparities and the inherent challenge in genetically examining cremated individuals have contributed to the complexity of its understanding and its coexistence with older traditions.

To shed light onto the population dynamics within the northeastern part of the Iberian Peninsula during the Late Bronze Age, we generated genome-wide data from 24 individuals inhumated in a collective "traditional" mound at the archaeological site of Los Castelletts II (Mequinenza), a necropolis where inhumation and cremation practices co-occurred for several centuries and where transfer of knowledge is under archaeological debate. Our results reveal no significant changes in their genetic profile of the individuals when compared with preceding local BA groups. However, our ancestral modeling shows a better fit with two mixed ancestry sources: one more enriched in steppe-related ancestry and a second more enriched in central/western Mediterranean ancestry than locally preceding BA populations. Additionally, the results obtained from the biological relatedness analysis showed that all buried individuals were biologically related, ranging from 2nd to 6-7th degree. More specifically, we identified one adult male with significantly more relatives than any other individual at the mound. This suggests that the tumulus represented a single extended family mausoleum.

13 LATE BRONZE AGE AND EARLY IRON AGE FUNERARY RITES IN SOUTHERN CARPATHIAN BASIN: LOCAL PRACTICES BETWEEN GREAT WORLDS

Ložnjak Dizdar, Daria (Institute of Archaeology, Zagreb, Croatia)

The southern Carpathian Basin, with its diverse landscape, has great communication lines along the Drava, Sava, and Danube, which affected the different flows of ideas and partial adoptions of funerary rites. During the Late Bronze Age, and especially at the beginning of the Early Iron Age, the funerary rites in the southern Carpathian Basin sat at the border between different worlds. During the Bronze and Iron Ages, the dominant form of burial in the Balkans was inhumation; in the Pannonian Plain, it was cremation. In the Balkans, burial under tumuli was practised throughout the Bronze Age and spread to the north in the Iron Age.

This lecture will present the local and regional variations in funerary rites on the border of different worlds and periods, but also the different networks of contacts that influenced this archaeological picture. The transfer of knowledge in funerary rites is visible archaeologically in the perception and (non)adoption of parts of the rite by contacts, non-acceptance of changes (e.g. longer practice of cremation), changes in societies (e.g. tumuli) and adaptation to the economic capacities of communities (e.g. portions of meat in graves). Local and regional customs are interwoven into a meticulous tapestry of material and spiritual contacts, exchanges, adoptions and changes from the 11th to the 7th century BC. It is important to recognize that this intensive tapestry includes the threads of individual differences, which were influenced by the identity of the deceased and the communal decisions about the funeral. Preserved material evidence and multidisciplinary analyses (anthropological, zooarchaeological, radiocarbon, organic residue anal-

ysis, stable isotope analysis) provide data for archaeological reconstructions and interpretations of funerary rites. We almost always use intuition to reconstruct the lost pieces of the puzzle of material culture.

14 THE TRACES OF THE FUNERARY RITE WITH CINERARY URNS IN TUMULAR NECROPOLISES IN KOSOVA AND NORTHEASTERN ALBANIA

Buqinca, Arianit (Institute of Albanology)

The remnants of the burial ceremony involving cinerary urns in tumular necropolises found in Kosova and northeastern Albania hold significant historical and cultural value. The existence and utilisations of urns associated with the non-tumular burial custom of Bërnica in Kosovo is a distinguishing feature of the transitional period between the late Bronze Age and the early Iron Age. This practice is predominantly observed in the flat burial grounds known as the “Urnfield Culture” in Bërnica, predominantly located in eastern Kosovo. It is worth noting that this ceremonial tradition ceases during the subsequent phase of the iron age. Nonetheless, although in significantly reduced frequency, urns are still encountered in the tumulus burial sites from the 7th to 6th centuries BC, such as Shirokë, Kënetë, Volljakë-Dush, Ujzë, and Karagaç. While the occurrence of this practice declines even further in the tumular necropolises of the 6th to 5th centuries BC. In the event that the so-called culture the urnfields culture or Bërnica is indeed associated with “urnfield culture” of north-west Europe, so it becomes paramount to acknowledge the northern origine of these “rites” during the transitional phase between the Bronze Age and the Iron Age, followed by a swift assimilation into the local culture. Typically, these burial mounds were attributed to a tribal collective or a closely related family, thus the coexistence of multiple burial customs within the same mound, during approximate time periods, serves as evidence of religious disparities and temporal variations. Particularly, the practice of interring the urn containing the ashes of the deceased in the central and initial grave of the mound, as observed in the tumulus of Shiroka, Ujza, Karagaç, and Volljaka, stands as the most compelling testament to this alignment.

15 BETWEEN THE ALPS AND THE JURA MOUNTAINS: KNOWLEDGE TRANSFER AND EARLY IRON AGE BURIAL MOUNDS IN WESTERN SWITZERLAND

Geitlinger, Timo (University of Zurich)

During the Early Iron Age, western Switzerland is a key area in between the Alps and the Jura mountains, connecting the upper Rhine valley and the Rhone basin. Looking at the *longue durée*, the Early Iron Age burial mounds are preceded by Middle Bronze Age mounds and Late Bronze Age flat burials and succeeded by Late Iron Age flat graves. A similar, yet regionally more divergent pattern can also be reconstructed for the fluctuation between cremation and inhumation burials. Early Iron Age burial mounds have been subject of some meritorious compilations (Drack 1958, 1959, 1960, 1961; Dunning 2004), yet, neither their landscape context, nor their relationship with each other have so far been systematically studied.

This paper presents preliminary results of a dissertation project and focuses on the Early Iron Age burialscape of western Switzerland. Looking at their spatial distribution and changing similarity connections, the spatio-temporal development of the burial mounds is approached. By these means, differences in how burials reference earlier monuments, how they connect with adjacent areas, and their relationship with each other manifest themselves in the burial context. As will be argued, this sheds light on potential Early Iron Age routes and circulation areas of knowledge transfer in western Switzerland.

16 A NECROPOLIS IN NETWORK: THE CASE OF GELOUX (LANDES, FRANCE) DURING THE IRON AGE

Bertaud, Alexandre (Archaeological service, Département du Lot)

The necropolis of Geloux (Landes, France), recently excavated, offers the possibility to understand the practices of a specific group through time. Indeed, the funerary practices allow for approaching the complexity of the organization of a local group and its connections concerning the ideologies related to death. The building of burial mounds and peripheral, associated graves, during the First Iron age on the one hand, and the subsequent reorganization of the funerary space during the Second Iron age on the other hand will be analysed in relation with other practices observed throughout Europe. The erection of mounds shows strong connections with northern horizons, especially in relation with the division of space. Whereas the building techniques can be interpreted in terms of knowledge transfer, they were adapted to local resources, especially wood. Grave goods are the other main field through which exchanges can be observed. From one period to another, grave goods change and reflect a more or less strong integration into wide exchange networks. This is particularly visible during the Second Iron Age when metal artefacts are associated with different material cultures of the centre of Europe or the Atlantic regions. The transfer of goods and knowledge influence the creation of a specific material culture in the Landes during the Iron Age, and the funerary record is the main expression of that process.

1015 ETERNAL REST IN THE WEST: FUNERARY CONTEXTS IN WESTERN MEDITERRANEAN PROTOHISTORY

Session theme: 6. The Mediterranean from Within

Session organisers: Carbonell Pastor, Sonia (Grup Arqueològic de Recerca Protohistòrica (GRAP). Universitat de Barcelona) - Smith, Alexander (Assistant Professor of Anthropology. SUNY Brockport University) - Coll Sabater, Margalida (Grupo de Investigación de Arqueología Mediterránea (GRACME). Universitat Pompeu Fabra)

Session format: Regular session

In recent decades, there has been a proliferation of research on the mobility of human groups during different periods. The Mediterranean was both an agent of unification and confluence for many cultures that developed during the 1st millennium BCE. At the same time, local cultures took on different forms, exhibiting variations based on where they developed and the nature of contact between different socio-economic groups and external or foreign actors.

This diversity of circumstances translates into the development of distinctive cultural characteristics that are understood as defining elements of the social groups that adopt them. In this session we will focus on one of the more potent material manifestations of the cultural dimension of these past groups: funerary materiality. Our aim is to provide a space for meeting and discussing the changes observed in funerary practices in different scenarios in the central and western Mediterranean focusing on the chronological period compressed between the 6th and 1st centuries BCE.

For this reason, this session will be oriented towards reflection and debate on different theoretical and methodological proposals, along with new narratives and methodologies that deal with the subject of death during the protohistoric era of the central and western Mediterranean.

This session will be open to various proposals on the proposed theme, some of the possible points for discussion will be:

- Techniques for documenting and excavating archaeological contexts. Excavation problems and strategies for solving them, such as documentary recording in fieldwork (documentary workflow, how the information is subsequently managed and the results obtained) can be addressed.

- New techniques applied to the study of funerary materiality. Studies derived from applied sciences (micromorphology, palynology, carpology, content analysis, etc.), implemented techniques (GIS, automatic remote sensing, photogrammetry, etc.) can be addressed.

- Comparisons of data and interpretation. Discussions of differing and variable funerary practices in the central and western Mediterranean with an eye toward a comparative regional lens, including grave types, treatment of the body based on age, sex, or gender, ritual practices surrounding interment, and funerary architecture.

- Knowledge Transfer. This is one of the least studied lines in the study of funerary materiality, perhaps because of the difficulty of its approach. By this we mean all the actions aimed at communicating to the general public how death was conceived in protohistoric Mediterranean societies and at making this knowledge accessible to everyone.

ABSTRACTS

1 DEATH ACROSS THE MEDITERRANEAN AND BEYOND: RITUAL SIGNIFICANCE AND COMPARATIVE ANALYSIS OF TOMBS FROM THE BALEARIC ISLANDS, ARABIA, AND PERSIA

Ramsay, Jennifer (State University of New York Brockport) - Smith, Alex (State University of New York Brockport)

The act of burial, a deeply ingrained ritual in ancient societies, reflects unique cultural nuances and symbolic representations. While burial practices vary widely across different civilizations, comparative analysis offers valuable insights into the underlying meanings and societal values embedded within these rituals.

This paper explores the rock-cut tombs of Menorca, Spain, dating back to the Iron Age, and examines their similarities with the Nabatean tombs of Arabia and the Persian tombs of Naqsh-e Rostam in Iran. Despite originating from distinct geographical and cultural contexts, these tombs exhibit intriguing morphological resemblances that warrant examination and interpretation. Their shared chronological timeframe provides a compelling opportunity to explore potential influences and interconnections, albeit speculative in nature.

By juxtaposing these burial traditions, the paper aims to illuminate previously overlooked connections within the Mediterranean world. Through this comparative study, we endeavor to deepen our understanding of the region's interconnectedness and unravel hidden layers of cultural exchange and influence. Ultimately, this exploration contributes to a more nuanced comprehension of ancient burial practices and their role in shaping Mediterranean societies.

2 RITUAL PRACTICES IN PROTOHISTORIC MENORCA: THE COURTYARDS OF THE ROCK-CUT TOMBS

Carbonell Pastor, Sonia (Grup de Recerca en Arqueologia Protohistòrica (GRAP)) - Coll Sabater, Margalida (GRACME)

During the second half of the 1st millennium BCE, a series of changes occurred in the postalalyotic society of Menorca. The interactions with external groups and the progressive social complexity acquired by the Menorca local groups were reflected in the funerary sphere. These changes are evident in funerary spaces, the so-called artificial caves or rock-cut tombs, as well as in ritual practices associated with these environments. This work presents the initial results of excavations carried out in the front courtyard of one of these artificial caves, specifically cave No. 45. The courtyards, open outdoor spaces carved into the rock, precede the entrance to the artificial caves. Multiple theories exist regarding the functionality of these spaces, with one suggesting a connection to the ritual practices and beliefs of the human groups that utilized them. However, very few archaeological interventions have been conducted to truly understand why they were used and for what exactly. The excavation of this space, carried out from a new methodological perspective, addresses several questions: What was its functionality? Were they covered with water, as some authors suggest? What significance could it have in the context of funerary ritual practices? What was its last moment of use? What was the human group like that built this cave?

3 FROM DARKNESS TO LIGHT: LATE IRON AGE CHILDREN'S BURIALS IN MALLORCA

Coll Sabater, Margalida (GRACME- Universitat Pompeu Fabra; ArqueoUIB- Universitat de les Illes Balears) - García Rosselló, Jaume (ArqueoUIB- Universitat de les Illes Balears) - Calvo Trias, Manuel (ArqueoUIB- Universitat de les Illes Balears)

During the Late Iron Age in Mallorca (550-123 BC), a unique funerary practice emerged for young individuals, marked by their placement in various containers across the island. Initially, infant containers were positioned alongside other community members, but later, they were isolated in exclusive areas. Anthropological data reveal that these individuals, fetuses, newborns, and very young infants, were deposited in ceramics and limestone containers upon death, symbolically safeguarding them, reminiscent of the maternal womb.

This distinct treatment compared to adults is also reflected in the activities conducted by the living in connection with the deceased. Infants are not adorned, dressed, or included in ritual consumption, lacking funerary offerings. Their involvement in funeral activities is less pronounced than in adult burials. In an initial phase, both infants and adults share the same burial spaces, humid caves with characteristic smells and darkness. However, from the 2nd century BC onward, the community decides that infants should be moved from the caves to open-air spaces exclusively designated for their burials.

Although they remain within the darkness of their small personal caves, the containers, the ones truly emerging into the brightness of the outdoors are the living individuals who participate in the burial process. The light, along with the spaciousness of the new areas, might suggest the realization of similar activities documented inside the caves, but quite the opposite; the only elements emerging from the caves are the infants. Therefore, we encounter a distinctive form of burial manifested through the safeguarding of containers, the phenomenological variety within spaces, and, principally, the omission of specific rituals by the living.

4 THE SOCIAL STRUCTURE THROUGH THE NECROPOLISES: POWERFUL WOMEN IN THE THE FUNERARY SPACES OF THE SOUTHEAST IBERIAN PENINSULA

San Quirico-García, Raquel (Universidad de Alicante)

The aim of this contribution is to propose new interpretations on the role of women in the communities of the Iberian Iron Age in the southeast of the Iberian Peninsula. A model of social organisation with women as an essential axis in the structures of power is based on the study of several necropolises located in this area. These funerary areas cover a wide chronological framework that shows the evolution of this society over the centuries.

Thanks to anthropological studies of the bone remains of the tombs, we know of the high presence of women in the necropolis in the central centuries of the first millennium BC. Many of them are also found in prominent places, inaugurating burial spaces that will give order to the necropolis and where new tombs will later be buried. Likewise, the grave goods that accompany them reveal a high social status, often related to productive activities, such as textiles, which were of great importance in the economic structure of these communities.

These aspects have led to some authors (Vives-Ferrándiz, Grau, Comino) to propose a model of social organisation based on bilateral descent and on heterarchical structures in which power is shared by various competing groups. Following these theoretical proposals, I am going to deeper into the archaeological interpretation of some of the most important necropolis of the area. The application of this socio-political schemes would also contribute to balance the androcentric view of Iberian society that has long been held and incongruously, given the archaeological evidence.

5 CARTHAGE IN GADIR. ANALYSIS OF THE NEW PUNIC-CARTHAGINIAN FUNERARY ASSEMBLAGE FROM C/ HUERTA DEL OBISPO 9-13 (CÁDIZ, SPAIN)

Pérez Infantes, Carolina (Universidad de Cádiz; Balteus, Arqueología y Patrimonio; PAIDI HUM-509 Research group) - Niveau-de-Villedary-y-Mariñas, Ana (Universidad de Cádiz; PAIDI HUM-509 Research group) - Legupín-Tubío, Isaac (Balteus, Arqueología y Patrimonio) - Martelo-Fernández, Marcos (Balteus, Arqueología y Patrimonio) - López-Sánchez, Natalia (Universidad de Cádiz; PAIDI HUM-509 Research group) - Sicre-González, Pablo (Universidad de Cádiz; PAIDI HUM-509 Research group)

The recent discovery of a Punic funerary ensemble in the necropolis of Gadir allows us to re-evaluate the extent of the footprint left by the Carthaginians in the Far Western city after the end of the Second Punic War.

The characteristics of the burial pit, the typology of the graves and the composition of the crockery in this context are different from the usual ones in Gadir and are, in turn, reminiscent of the funerary and ritual expressions of the central Mediterranean.

The fact that the complex is dated to a historical moment (end of the 3rd - beginning of the 2nd century BC) when, according to the sources, Gadir had already achieved its total separation from the North African state, indicates that the reality must not have conformed so closely to what the Roman propaganda has conveyed and that the Gadirites and the new arrivals continued to coexist in the city with the individuals from North Africa, who maintained their funerary customs and beliefs.

6 "GLOCALIZED" IN DEATH? FUNERARY PRACTICES IN HELLENISTIC NORTH INLAND ETRURIA

O'Donoghue, Eoin (Brandeis University)

This paper will examine funerary practices in North Inland Etruria between the 4th and 2nd centuries BCE. The specific area examined here is bound by the Chianti hills to the north and Monte Amiata to south, to the west by the Colline Metallifere, and the Apennines to the east. In the period considered here it comprised small urban communities that controlled dispersed rural agricultural populations. This contrasts with the well-established city-states of South and Coastal Etruria with large urban centers that are often described as metropolises. A curious feature of the funerary traditions of this region is the homogenous nature of burial practices. The dominant rite was cremation and burial in cinerary urns that were placed within chamber tombs associated with the descent group. This consistency is remarkable even if some variation exists chronologically and, in the form, the cinerary urns take; it contrasts sharply with the diverse funerary practices of the Coastal and Southern Etruscan city-states. The uniformity in practice is echoed within regional groupings with epigraphic evidence demonstrating exogamic connections between socio-political networks across the region, especially in the area around Chiusi, but it is also apparent around Asciano and Siena. This paper seeks to understand how and why there is such cohesion in funerary practices. It will argue that the limited urban character of the settlements enabled greater socio-political cooperation, rather than competition as it did elsewhere in central Italy. Another related focus will be how these communities engaged with the pan-Mediterranean cultural phenomenon of "Hellenization. This is clearly seen in the region's burials through the presence of highly ornate personal items, black gloss pottery, and the representation of Greek myths on cinerary urns. This engagement with the material cultural trends of central Italy and the Mediterranean will be interpreted through the lens of a "glocalizing" framework.

7 DEATH IS DRESSED IN WHITE. NEW FUNERARY MONUMENTALITY IN THE BRONZE AGE IN GALICIA (NW OF IBERIA)

Prieto-Martínez, M. Pilar (University of Santiago de Compostela; CISPAC) - Cordeiro-Maañón, Luis (University of Santiago de Compostela) - Alonso-Toucido, Francisco (Tempos Arqueólogos SL)

The so-called circular enclosures in Galicia are a new type of site identified in 2006 for the first time, 8 sites have been excavated so far and their formal characteristics are beginning to be defined but their functional interpretation is still controversial. We call them 'roda type' (Galician word that means wheel) because it is its most common toponym and its formal imprint on the landscape. We think that the 'rodas' respond to a new type of funerary monumentality unknown in Galicia at the end of the second half of the second millennium BC in accordance with the new European social rationality.

The objective of this presentation is to show the validity of this hypothesis based on various methodologies and sources of information: (1) Based on the data obtained in the excavation of O Corro dos Mouros site (Adai, Lugo province) and establishing a comparison with 7 other sites excavated so far. (2) Based on field survey data and laboratory work with cartography, aerial photography, LiDAR and GIS from 50 sites distributed throughout the region. The results will be aimed at defining more adequately the 'roda' type contexts: architectural features, material culture, radiocarbon dates, function and distribution and location patterns, hoping that it will allow us to more adequately focus this type of sites in their regional and European context.

1016 INTRA-MURAL BURIALS AND THEIR CULTURAL LANDSCAPE IN EUROPE AND THE MEDITERRANEAN FROM PREHISTORY TO THE MIDDLE AGES

Session theme: 6. The Mediterranean from Within

Session organisers: Fulminante, Francesca (Bristol University; Oxford University; University Roma Tre) - Laneri, Nicola (University of Catania; University La Sapienza) - Hodson, Claire (Durham University)

Session format: Regular session

Discussant: Prof. Paolo Carafa, University "La Sapienza."

The use of intra-mural graves within the city walls as well as in private houses and palaces as part of the funerary customs of ancient societies of both the Old and New World is a widely spread phenomenon in the history of humankind. In fact, the presence of these graves is in fact recognizable in numerous archaeological contexts that can be interpreted, for example, as an archaeological indicator of the cult of the ancestors.

In this session we aim to discuss intra-mural burials within European and Mediterranean contexts in relation to their different ritual, cultural, economic, social, and political landscape. From a quick review of studies in intra-mural burials it seems that, while there are some examples from continental Europe as well, the phenomenon seems to have its origin in the Near East in the Neolithic. Then it travels to the Aegean and Greece during the Bronze and Iron Age when it reaches the central Mediterranean as well, but not in all regions homogeneously. For example, in central Italy they are present in Latium vetus but not in Etruria. During the Republican and Imperial Period, they are found both in Italy and the Provinces and finally in the Middle Ages they are present as children burial around the churches both in Europe and the Mediterranean.

By definition, the existence of intra-mural burials is related to the beginning of settled life and the first villages in the Near East, but which is the significance of intra-mural burials for their communities? Is there a link between expanding urbanization and intra-mural burials? Which is the ritual, social, political, and economic significance of intra-mural burial across space and time? To discuss these issues and possibly find some answers collectively we ask for papers, which discuss intra-mural burials, either of children or adult, in relation to their cultural landscape to allow a comparative, multi-regional and diachronic perspective.

ABSTRACTS

1 **CHERISHED LIVES: EXPLORING INTRA-MURAL INFANT BURIALS IN CHALCOLITHIC ASIA MINOR**

Yildirim, Burcu (Leiden University, Faculty of Archaeology) - Hackley, Laurel (The University of Memphis, Department of Art and Design)

Intra-mural burials within Chalcolithic communities of Asia Minor are visible signs of enduring ritual practices, passing down through generations amidst changing social dynamics and spatial arrangements. Particularly notable are infant burials, which are part of a broader ritual tradition involving special deposits, preserving ancestral memory, and ensuring continuity in religious beliefs over centuries. Despite changes in social organization, the consistent presence of these burial rituals highlights their significant impact on community identity and religious practices over time. This research aims to provide a clear understanding of the social importance of fetal, infant, and child burials, ultimately contributing to our knowledge of how the lives and deaths of these young individuals may have influenced the development of complex social networks. Methodologically, the study uses archaeological analysis and interpretation, focusing on sites across Asia Minor, with specific attention to Çadır Höyük, to investigate the practice of in-site infant burials within the broader socio-cultural context of the Chalcolithic period. Through this interdisciplinary approach, the research aims to deepen our understanding of the complex relationship between burial practices, social dynamics, and cultural continuity in ancient communities.

2 **INTRAMURAL BURIALS DURING THE CHALCOLITHIC PERIOD OF THE SOUTHERN LEVANT**

Gošić, Milena (Department of Archaeology, University of Belgrade)

The Chalcolithic period of the southern Levant is known for the diversity of its rituals and burial practices, including extramural primary and secondary burials and intramural primary burials. Most of the scholarly attention has been devoted to extramural secondary burial, except for the early Chalcolithic settlement at Gilat, which features numerous intramural primary burials that were extensively published. However, intramural primary burials are present, usually in small numbers, at most Chalcolithic settlements. They are commonly interpreted as a sign of continuity with the earlier period, unlike the secondary burials in ossuaries that are understood as a possible foreign influence. They are usually found in flexed positions in pits of various sizes and with no apparent burial offering. The present paper aims to offer a comprehensive overview of the available data on intramural burial to see if these burials have common traits

3 **THE KISPUM IN THE HOUSE: MATERIAL RELIGION AT TELL MUHAMMAD, BAGHDAD, DURING THE OLD BABYLONIAN PERIOD**

Russo, Sergio (University of Catania) - Pappalardo, Chiara (University of Catania) - Laneri, Nicola (University of Catania)

Drawing upon archaeological evidence, this paper investigates the role of the kispum ritual in framing domestic religiosity at Tell Muhammad (Baghdad) during the Old Babylonian period. The kispum is an ancient Mesopotamian family funerary ritual performed regularly to commemorate the ancestors. Typical of the second millennium BCE, according mainly to written sources, it involved libations, food offerings, and invocations of the dead. Texts also inform us that the kispum could be performed in different places, either within the domestic space, on an altar before family intramural tombs or at the gravesite. In the house, the ritual occurred in the aširtum, generally the rear hall or room of the building. This space had built-in ritual furnishings, including altars or platforms, small fireplaces, and libation pipes. Archaeologically, such contexts have been found in a few settlements, such as Ur and Sippar Jahrum. However, recent excavations at the Old Babylonian site of Tell Muhammad, within the metropolitan area of Baghdad, have unveiled new, outstanding material evidence for the occurrence of the kispum. In the rear room of the so-called House 1, in fact, the presence of an altar for pouring water, several pot burials and offerings, and fire traces clearly indicate the existence of an aširtum, the ritual space in which the kispum was performed. By contextually analysing such fresh material evidence, this case study offers the opportunity to shed light on family-based ritual and religious practices, thereby enriching our comprehension of the relationship between material culture, the mortal remains of the deceased, and funerary spaces in the creation of forms of ancestral commemoration of the dead in the lived experiences of Old Babylonian society.

4 **CRADLE AND GRAVE: INFANT INTRAMURAL BURIALS IN THE EBRO VALLEY FROM BRONZE AGE TO THE BEGINNING OF 20TH CENTURY AD**

Salcines-Montaña, Javier (University of Valladolid) - Fernández-Crespo, Teresa (University of Valladolid)

Infant intramural burial was a funerary treatment, mainly restricted to perinatal individuals, that was essentially practiced during the Late Bronze and Iron Ages in some western Mediterranean regions, including Iberia. There, while cremation was the main funerary practice for the aforementioned periods, more than 800 infant intramural burials have been identified, particularly in north-eastern and central regions. The exceptionally high number of burials recorded in some sites of the upper-middle Ebro valley such as La Hoya (n = 260) or Atxa (n = 49) is particularly noteworthy, while the rest rarely exceed a dozen. Available radiocarbon dating suggests that the phenomenon could have begun around the 10th century BC in the Ebro valley, and continued after the end of the 1st millennium BC, when Rome conquered and occupied the territories, and even far beyond. Surprisingly, this region has provided evidence of infant intramural burials in medieval and modern sites and for contemporary ethnographic accounts, which describe the persistence of such burials as late as the first quarter of the 20th century. Here, we present one of the longest regional diachronic sequences for infant intramural burials detected in Europe revealing interesting patterns of continuities and discontinuities over time.

5 **INTRA-MURAL INFANT BURIALS IN IRON AGE LATIUM VETUS IN THE WIDER CONTEXT OF THE MEDITERRANEAN PREHISTORY: WORK IN PROGRESS**

De Paolis, Paolo (Sapienza Università di Roma) - Fulminante, Francesca (University of Bristol; University of Oxford; Università Roma Tre)

In Latium Vetus infant burials in inhabited areas are documented in ritual contexts (especially in Rome) and in domestic contexts. In this last case, the phenomenon of the so-called suggrundaria is well known, and can be found in Ficana, Fidenae, Satricum, Gabii et al. but also in Rome itself, during Iron and Orientalizing Age. The documentation regarding these phases is rather relevant but lesser and lesser during the later phases. These are very simple burials: children, usually under 3 years old, are often placed in amphora or between tiles, with poor burial objects or totally absent, although there are sporadic cases of infants that seem to receive particular consideration.

In aims with the objective of the session, in this paper we aim to present the phenomenon of suggrundaria in central Italy in the wider context of Mediterranean Prehistory. As emphasised in the session call there seems to be some general transmission from east to west, from the Neolithic onwards, and a particular significant within settled communities. But which is the ritual, social, political, and economic significance of intra-mural burial across space and time?

Without the ambition to be exhaustive we will collect some of the material published in the last few decades in order to have a first assessment of these issues to propose and discuss together with the research and evidence discussed by other colleagues.

6 **BABIES IN THE YARD: EXPLORING THE OSTEOLOGICAL AND CONTEXTUAL IMPLICATIONS OF 41 INFANT BURIALS AT YEWDEN ROMAN VILLA, HAMBLEDON, ENGLAND**

Hodson, Claire (Durham University) - Pitt, Rebecca (University of Reading)

Excavations in 1912 at Yewden Villa, Hambledon in south-west Buckinghamshire, England, revealed 97 infant burials dating to the Roman period (1st-4th century CE). All but two were recovered from an enclosed area to the north of the main villa, nicknamed 'the yard' by the excavators. Although not all these infant skeletal remains have survived for analysis today, recent reassessment has identified a total of at least 64 non-adults aged up to 1.5 years from articulated and disarticulated material. Of these skeletons, 41 (64%) fetuses and perinates (aged below 42 weeks of gestational age) were identified. Previous studies have focused on the superfluity of these very young individuals, many of whom are suggested to have died around the time of birth (circa 40 gestational weeks), using such evidence to support a narrative for infanticide. Yewden Villa complex has consequently, also been interpreted as a 'brothel', owing to the high number of foetal-perinatal individuals buried here. Yet, intra-mural burials of foetal, perinatal, and infant individuals are abundant with Romano-British villa complexes; why then is Yewden purported to be different? This paper presents a reanalysis of the foetal-infant individuals, exploring evidence of palaeopathological changes, growth disruption and early-life experiences which may have impacted these brief lives. As such, considerations of community practices associated with infant care and death, as well as the sociocultural, ritual, and political landscapes within which these young individuals were buried, will be discussed. Consequently, the authors present an alternative narrative; both the temporal longevity of this burial tradition, as well as a myriad of biocultural factors, should be considered in the context of infant mortality, and demonstrates the continued practice of deliberate and careful burial of these young individuals within the yard at Yewden Villa.

7 **INTRA-MURAL VS URBAN BURIALS IN CRETE: AN EARLY BYZANTINE MEDITERRANEAN PERSPECTIVE**

Lapacciana, Nicola (Sapienza)

Analysing post-Roman funerary contexts approaching urban living spaces encounters the need to define specific scopes and conventional categories to frame a complex phenomenon susceptible to interpretative ambiguities. This difficulty often originates from the impossibility of nailing down what can be interpreted as "urban space" from an anthropological-cultural and topographical perspective. Over the years, the study of these themes has been primarily Western-centric, heavily based on Italian urban archaeology cases. The discussion on this topic has revolved around a clear and conventional limit that eases the definition of "urban burials," namely the presence of urban walls. The expression "Intra-mural" reflects an interpretation of the phenomenon tied to a well-established model of post-Roman cities derived from studies in Western contexts. However, such a scheme is not always applicable to the "urban image" that the research on the early Byzantine city is revealing.

In Eastern contexts, there are frequent examples of cities only partially enclosed by walls during the early Byzantine period or only later provided with a defensive system. Furthermore, the discovery of burials within urban areas during the changing early Byzantine era raises questions regarding the laws implemented by the centralized state to regulate this phenomenon, as they contrast with the seemingly divergent archaeological data.

The case of Cretan cities, especially Gortyn, well encapsulates the issue. Due to its position in the eastern Mediterranean, Crete is a privileged case study on urban transformations between the 5th and 8th centuries. Its unique urban history is influenced by specific geographical, historical and cultural factors. The cases presented in this contribution thus seem to emphasize the need to address new methodological and terminological issues to define the study areas regarding the relationship between the living spaces and the spaces of the dead, resulting from dissimilar dynamics of urban transformation across the Mediterranean.

1018 **MORE THAN JUST DATA: THE ROLE OF ARCHAEOLOGICAL THEORY IN REFINING GEOSCIENCE-DRIVEN RESEARCH QUESTIONS**

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Costanzo, Stefano (Department of Earth Sciences, University of Milan) - Wright, David (Department of Archaeology, Conservation and History, University of Oslo) - Loftus, Emma (Institute for Prehistory, Ludwig Maximilian University Munich) - Sulas, Federica (Department of Historical Studies, University of Gothenburg) - Lane, Paul Jeremy (University of Cambridge)

Session format: Regular session

Since the establishment of humans as active ecosystem engineers, every performed action came with consequences. Whether intentional for improving subsistence opportunities in certain locations, or unintentional catalysts of novel geogenic processes in otherwise stable environments, landscape modifications and niches construction have had direct or downstream impacts on ecosystem evolutionary pathways. Notable examples include the diversion of rivers and the construction of canals, which may have stimulated new forms of farming; husbandry in semi-arid margins, which may have caused loss of inhabitable and cultivable land; intensive deforestation worldwide, which has caused slope instability and enhanced alluviation of valleys. In later times, the construction of dams in indigenous lands caused severe disruptions in the local economies of upstream and downstream population.

In past research, some instances of cause-and-effect were easily deciphered thanks to the magnitude of the land modifications, sometimes with iconography and historiography providing motives and precise time brackets. However, when examining data from events at smaller scales, causality and rationales attributed to past communities often were subject to environmentally deterministic and oversimplified interpretations. Such interpretations ultimately risk leading to flawed paradigms. Nowadays, in the light of post-processualism and the widely shared idea that human agency is ultimately driven by composite and cumulative individual experiences, geoarchaeologists are tasked with tackling interpretational riddles acknowledging the full spectrum of theories belonging to the archaeological and social sciences at large. This session welcomes novel studies, review works and paradigmatic challenges throughout all ages and across geographies and climates. We aim to showcase the full and real potential of applied geosciences in solving variously-paced complex entanglements between human agency, landscape modifications and societal changes, when supported by solid and sensible theory.

ABSTRACTS

1 **BUNDLE OF STICKS: WEAVING ARCHAEOLOGICAL TAPESTRIES FROM CABLES OF GEOSCIENTIFIC RESEARCH**

Wright, David (University of Oslo)

In a series of papers near the turn of the millennium, Alison Wylie argued for 'cabling' the past to build solid archaeological interpretations. By interlacing independent strands of evidence, she argues that the basis of archaeological inquiry is able to get beyond the paradox that 'the data do not speak for themselves' yet overcome the overly subjective 'anything goes' approach of relativism. The incorporation of geoscientific tools into archaeology has opened new possibilities to cable the archaeological past, but it also offers the temptation to engage in what Tim Sørensen calls 'the fetishization of data'. In the absence of solid archaeological theory, geoarchaeological information becomes white noise that is difficult for all but a few specialists to understand. Here, I argue that the construction of so many independent cables of knowledge about the human past has opened previously unimagined possibilities to build tapestries of understanding. However in the absence of solid archaeological theory and commitment to address the so-called 'Grand Challenges' of archaeological research, geoarchaeology risks becoming a navel-gazing subdiscipline that speaks only to itself. The effective incorporation of theory into geoarchaeology will allow for the construction of a human past in the form of a clear, interpretable tapestry predicated on solid, testable facts.

2 **EVOLUTIONARY GAME THEORY LINKS ANCIENT DEMOGRAPHY, LANDSCAPE, AND PALEOENVIRONMENT TO EXPLAIN THE CULTURAL TRANSFORMATION OF SAMOA**

Cochrane, Ethan (University of Auckland)

In this research we identify the evolutionary-ecological processes that explain 1000 years of behavioural change recorded in landscape modifications and geoscience data from the Polynesian islands of Samoa. Our analyses combine lidar mapping and ground survey to reveal an extensive landscape of archaeological features: rock walls, ditches, and platforms, linked in a robust feature chronology. Soil nutrient analyses and geoarchaeological coring indicate spatial differences in the agricultural potential of the valley, and human modification of the environment over time. Our results demonstrate that the construction of large rock walls, some several hundred meters long, began approximately

900-600 years ago, shortly after dramatic population rise in Sāmoa. This was followed by the building of small rock walls, often enclosing rectilinear fields or platforms. Densities of both rock wall types are associated with areas of higher agricultural potential. The earliest wall construction was penecontemporaneous with partial forest removal that created a more productive wetland environment in the southeastern region of the valley, an area later a focus of agricultural ditching. We propose that with population rise the variable fertility of agricultural land became a significant resource gradient, influencing the population in two ways. First, areas of more fertile agricultural land promoted territorial behaviour, including large rock walls, and led to a familiar collective action problem. Second, niche construction in the form of human-mediated forest removal created a productive wetland agricultural system that was enhanced with a reticulate ditch network, the maintenance of which also led to a collective action problem. We conclude that in Sāmoa, collective action problems were the cause of increased social hierarchy and may underlie the origins of complex society throughout Polynesia.

3 THE MORE THINGS CHANGE? INTERPRETING LONG-TERM HUMAN-ENVIRONMENT DYNAMICS ON THE NORTHERN COASTAL FLATS OF PAPUA NEW GUINEA

Golitzko, Mark (University of Notre Dame) - Uy, Mirko (University of Notre Dame) - Power, Mitchell (Utah Museum of Natural History; University of Utah) - Berke, Melissa (University of Notre Dame)

Archaeologists working in lowland tropical environments have often struggled to fit their data into models of domestication and resource intensification borrowed wholesale from more temperate latitudes. What is sometimes called “neolithization” is often viewed as an inevitable process once human modified or domesticated plants and animals are available, after which the human footprint on the landscape dramatically increases. On New Guinea at present, a wide range of subsistence modes continue to be practiced, including intensive horticulture with substantial raising and tending of animals, arboriculture, mobile hunting and gathering, or even trading to obtain the bulk of foodstuffs. Subsistence differences are often ascribed to either differences in environment and the productive capacity of land, or to historical contingency, whether and when people long resident on the island came into contact with particular language groups associated with the spread of root horticulture and stock rearing. We report results of coring and paleoenvironmental analysis in the Aitape area of northern lowland Papua New Guinea. At present, people there rely heavily on arboriculture and hunting, however, the history of subsistence practices and forest management are poorly understood. Using a number of environmental proxy measures including charcoal, geochemistry, and chemical biomarkers, we document both natural shifts in environment (sea-level rise and fall, formation of coastal flats, changes in ENSO intensity and frequency), as well as likely shifts in production strategy including periodic horticultural intensification as the landscape was reshaped dramatically after the mid-Holocene Thermal maximum, when major lagoon systems first formed and then in-filled. This study highlights the dynamism of environment near Aitape over the last 12,000 years, but also suggests that people living there remained flexible as to how they acquired resources and managed the local environment including possibly intentionally abandoning horticultural intensification when it proved unsustainable.

4 AMAZONIAN DARK EARTHS AS HUMAN NICHE CONSTRUCTION: EXPLORATION THROUGH GEOARCHAEOLOGICAL PROXIES

Sagan, Wiktoria (Institute of Archaeology, University College London) - Arroyo-Kalin, Manuel (Institute of Archaeology, University College London)

Amazonian Dark Earths (ADE or terra preta) have long been cited as an example of anthropogenic landscape management and a long-lasting ecological legacy of indigenous people of Amazonia. Current broad research questions about Amazonian Dark Earths revolve around their formation (anthropogenic/anthropic/natural), geographical spread, dating, usefulness to the present and future sustainability. On a local scale ADEs can inform about periods of occupation, socio-cultural stability and resilience, village layout, cultivation practices. Even though majority of archaeological studies into ADE are very localised, their conclusions are often extrapolated across the whole basin. Currently, one of the most pressing questions is what theoretical tools are appropriate for local scale interpretation of ADEs? The key emerging interpretative model for ADEs applicable at multiple scales of observation is the cultural niche construction theory. This paper will discuss the research outcomes and limitations of NCT as applied to recent archaeological research into ADEs. Then, based on a case study of an ongoing project in northwestern Brazil, we will focus on how geoarchaeological proxies can be used to answer specific questions that emerge from treating ADEs as culturally constructed niches.

5 PALAEOECOLOGY, OR MEDIA (ECO-)ARCHAEOLOGICAL SCULPTURING TO EVOKE CONCEPTUAL DISPLACEMENT. TOOLS TO REFORMULATE THE NATURE/HUMAN DIVIDE IN MESOLITHIC WETLAND ARCHAEOLOGY

Blaesild, Paulina (University of Gothenburg)

Palaeoecological studies, investigating environment history and interrelated anthropogenic signals, are commonly perceived as external proxies to archaeological practice and its respective scope of interests. The common understanding of landscape reconstruction as belonging to geo- or natural sciences; quaternary geology, biology or botany, contributes to a situation where cultural and natural heritage research objectives are (irreversibly) separated, as well as their study objects, archival records and means for past narration. These habitual, uncalled-for and classificatory conditioned systems mark a central problem for past environment/human studies as it creates obstacles for seamless research programs—further, it exemplifies a contemporary conceptual divide between nature and culture that is manifesting within research.

Questions on how to reflexively address definition constants, operating through intricate and historically (i.e., messy) interwoven systems of protocol, end up relying on theoretical frameworks to solve discursive knots. Still, structural change will require critical evaluation and initiative, applied within each particular site where archaeological knowledge production take place. It regards the archaeological site and instance of fieldwork as well as places for analysis like laboratories, offices or storage facilities where materials re-couple into new spatial/ecological networks. Reformulation and action are thereby inseparable, applying differently to each place and its network of people (employees, visitors), materials and datasets.

This paper deals with the reflexive responsibilities accompanying material sciences such as archaeology—focusing on ethical dimensions inherent in the narrating of nature, ecological dynamics and data-to-landscape translation acts, foundational for such interpretative works. The paper asks if theoretical frameworks may facilitate norm-critical models for past environment/human affairs, in turn with capacity to impact scientific inquiry systems. The discussion is set out from a study on Mesolithic wetland sites within the Dagsmosse basin, south-central Sweden, and a critical assessment of the preconditions enabling creations of site-specific, interpretative ecological models (with humans in them) at first stance.

6 CHALLENGES IN GLOBAL GEOARCHAEOLOGY: FROM GEOSCIENCES TO ARCHAEOLOGY AND BACK

Zerboni, Andrea (Università degli Studi di Milano, Dipartimento di Scienze della Terra “A. Desio”)

The application of Earth Sciences methodology to solve archaeological and anthropological questions has a long history. Since the second half of the last century, geoscientists and archaeologists have collaborated to investigate major issues related to the effects of climate and environmental changes on settlements, the exploitation of natural resources, and the formation and preservation of archaeological sites. Simultaneously, Archaeological Sciences have contributed to understanding the dynamics of natural processes in the Quaternary and to disentangling the contribution of humans in shaping our planet and modulating natural surface processes.

In this perspective, as geoarchaeologists, we may ask ourselves what the next step in collaboration between Earth Sciences and Archaeological/Anthropological Sciences is. Today, an increasing number of investigations are revealing the non-linear and complicated nexus between climate change, environmental modification, and human agency. These contributions explain that humankind’s imprint on natural processes started several millennia earlier than expected, well before the formal definition of the Anthropocene epoch that is ongoing. For that reason, one of the major challenges in Geoarchaeology is to investigate the archaeological record of human agency on pristine ecosystems and support the definition of the Anthropocene not merely as a geological epoch or event, but as the diachronic and geographically differentiated emergence of Homo sapiens as a major geological and geomorphological agent. Such occurrences are well-preserved in the archaeological record, and a synergic investigation can reveal their tempos and modi.

1021 EAA COMMUNITY FOR CLIMATE CHANGE AND HERITAGE (CCH) ROUNDTABLE

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Davies, Mairi (HES Historic Environment Scotland) - Martens, Vibeke (NIKU Norwegian Institute for Cultural Heritage Research) - Biehl, Peter (University of California, Santa Cruz)

Session format: Round table (without formal abstracts)

In September 2023, Climate Heritage Network launched a Global Call to Put Cultural Heritage, Arts and Creative Sectors at the Heart of Climate Action. A milestone was reached when the first ever high-level ministerial dialogue for culture-based climate action took place at COP28 in Dubai in December 2023. This is an important step towards

culture being included in the core work of the UN Framework Convention on Climate Change. How, though, can we ensure that cultural heritage, and archaeology, make a substantial and visible contribution to culture-based climate action? As we face the challenges of Net Zero and the Race to Resilience, we need tangible progress in ensuring that interdisciplinary research on responses of previous societies to environmental change informs our response to climate change. We have as background the statements on climate change and heritage released by the EAA 2021 (<https://www.e-a-a.org/2021Statement>), SACC 2021 (<https://www.jma.uni-kiel.de/en/research-projects/sacc/sacc-statement-2021.pdf>) and the SAA 2022 Statement on Climate Change and Cultural, which all point to different important aspects on how archaeology and archaeologists can contribute.

This eighth roundtable organized by the EAA Community for Climate Change and Heritage (CCH) builds on the success of the previous ones and hopes to focus further on the translation of archaeological research into practical adaptation and resilience solutions.

We are inviting representatives of key archaeology associations as well as specialists in climate change and heritage research as a sounding board for the CCH activities. The roundtable session will provide an update on the work done in and by the community since the previous meeting and discuss next steps for the Community to grow and extend its network and activities to help adapt to a global climate crisis, find good solutions for adaptation and thus increase heritage and societal resilience.

1022 RETHINKING ANCIENT MEDITERRANEAN INCARCERATION AND EXILE

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Larsen, Matthew (University of Copenhagen) - Letteney, Mark (University of Washington)

Session format: Regular session

Ancient traces of incarceration, exile, and other forms of punitive unfreedom have historically been ignored or under-documented, a problem stemming both from prevailing historiographic dogmas that prisons were at most a marginal element of pre-modern societies (Durkheim, Foucault, Mommsen) and the difficulty in securely identifying evidence and remains of these practices in ancient Mediterranean archaeological contexts. Yet various literary and documentary sources give ample evidence that sites of incarceration were commonplace in many cities and that exile was a widespread ancient practice. This session seeks to address this imbalance by inviting papers focused on material aspects of incarceration and exile in ancient Mediterranean contexts (600 BCE to 600 CE). The goal of the session is to explore how to identify such carceral spaces, what were the types and forms of such sites, who inhabited them (both as captors and those being detained), and how the public perceived and conceived of such spaces. Possible paper topics include: reports on prisons attested in archaeological excavations; analysis of inscriptions which relate to any aspect of the practices, spaces, or experience of incarceration; and visual materials which represent spaces of incarceration, prison personnel, or depictions of prisoners.

The three hour session will include six papers of fifteen minutes, a fifteen minute response from a specialist, and an hour and fifteen minutes of discussion.

ABSTRACTS

1 A CARCER CASTRENSIS IN VINDOBONA?

Mosser, Martin (Museen der Stadt Wien - Stadtarchäologie)

In the legionary fortress of Vindobona a special building could be identified during two construction projects of the last years. It is a cellar room reaching up to 4 m in depth and measuring 30 x 15 m, of which one cellar window was found to be completely preserved. At the western end of the building, the lowest steps of a stone staircase leading to an upper floor has been discovered. The room was additionally surrounded by outer walls, which makes it possible to reconstruct a corresponding circumferential corridor. At first, a storage building was suspected, but further research now suggests most likely a prison building (carcer castrensis) erected in the 3rd century AD. A prison of this size would be unique along the Pannonian Danube Limes. Comparisons with similarly structured cellars in Lambaesis, Simitthus or Sarmizegetusa should confirm this thesis, even if there is no clear evidence to date. Furthermore, the context in which a prison of this dimension is to be seen in connection with a legionary fortress must be considered. Were prisoners of war or slaves imprisoned here, or are convicted criminals simply to be assumed here?

2 THE CIVIC PRISON OF SUFETULA?

Letteney, Mark (University of Washington)

Little can be said for certain about the foundation of Sufetula (Subaytilah, Tunisia), though Roman inhabitation is evidenced from the middle of the first century CE forward, and the city's forum was heavily renovated in the middle

of the second century. At the northwest side of Sufetula's forum lies a spectacular triple Capitolium: three temples stand side-by-side, one likely dedicated to each of the three gods worshiped in the Capitoline Temple at Rome, each on a high, imposing pediment.

This paper will suggest that the central temple at Sufetula attests an otherwise unknown phenomenon of Roman municipal planning: a civic prison constructed underneath a Capitolium. While this particular combination of features at Sufetula are (thus far) unique, many of its characteristics are rather common. Second century contexts attest prisons underneath temples (Lambaesis), directly adjacent to the forum (Cuicul), and underneath civic tribunals (Sarmizegetusa). Architectural comparison with securely identified carceral spaces suggests the possibility that the area underneath the Capitoline temple at Sufetula served a similar function, and the parallel but distinct case of the triple Capitolium at Baelo Claudia offers further opportunity to understand Sufetula's forum as a unique concatenation of a common set of characteristics. In the end, I will suggest that it is more likely than not that the space was designed to serve as the Sufetula's civic prison.

3 EVERYDAY OBJECTS OF CONTAINMENT: THE REFLEXIVE USE OF ROMAN METAL OBJECTS DEPICTING CAPTIVES AND PUNISHMENT

Levitan, Rebecca (King's College London) - Pearce, John (King's College London)

Objects from Rome's northern provinces related to the captivity, incarceration, and the punishment of criminals are rare, and when they do emerge, their use and primary contexts often remain enigmatic. This paper examines two categories of these images taking the form of everyday metal objects, which were themselves likely used in processes of containment (locking and binding).

A unique copper-alloy key handle excavated from a town house in Roman Leicester decorated with two groups of figures likely depicts a scene of *damnatio ad bestias*: a manner of execution that was both punishment and spectacle (Pearce et al. 2021). As well as having affinities with other key handles in figural form, the Leicester object is stylistically similar to another class of copper-alloy objects – the so called “bound-captive figurines. About twenty of these small figures have been recovered in the northern provinces; all depict a seemingly naked captive or enslaved person bound around the neck, hands, and feet (Jackson 2005). The captive figures are perforated in two axes, implying that cords or straps were passed through the small bodies to wrap or bind, although the exact use of these objects remains unknown. In examining the reflexive nature of these objects, which both depict captives and themselves are tools of containment, we aim to interrogate ancient conceptions of unfreedom at the everyday scale.

4 THE RIGHT TO BIND: INCARCERATION IN ANCIENT ATHENS BETWEEN MATERIALITY AND IDEOLOGY

Lovisetto, Giovanni (Columbia University)

In ancient Greece, the semantics of incarceration prominently featured corporal binding, as evidenced by the designation of the incarcerated person as “the bound” (ὁ δεσμώτης) and the prison as “the place of those who are bound” (δεσμωτήριον). While literary sources confirm that inmates could indeed be physically bound, corporeal constraint does not seem to consistently characterize prison life. Challenging scholarly accounts that interpret this apparent incongruity solely in linguistic or pragmatic terms, this paper argues that the association between binding and imprisonment influenced the public perception of the latter, facilitating a rhetorical utilization of the prison space and the figure of the inmate for ideological and political purposes. First, Athenian legal speeches reveal how the binding aspect of incarceration was utilized to liken it to civic punitive measures involving physical restraint, such as the pillory, public torture, and execution – of which the shackled bodies from the Phaleron provide compelling material evidence. Orators grounded the polis' authority over these forms of restraint in the transition from private to state-regulated confinement, presented as a historical reality based on Solonic norms. Accordingly, in legal speeches, narratives about private incidents of unjust binding construed individual appropriation of the polis' “right to bind” as anti-democratic behavior undermining civic norms and fostering societal discord. Moreover, by mobilizing common associations of physical confinement with captivity and slavery, orators ideologically construed punitive forms of binding, including incarceration, as lawful, civic “degradation ceremonies” that temporarily altered the social standing of the convict. Significantly, all these narratives targeted members of the political elite. The paper ultimately illustrates how Athenian orators exploited the semantic link between imprisonment and restraint, partially grounded in material practices, to present incarceration as the polis' “right to bind. Thereby, they utilized incarceration to advance political and ideological objectives under the guise of promoting societal stability.

5 TRACES OF INCARCERATION FROM MARESHA: FROM BRONZE FIGURES TO PRISONER PETITIONS

Larsen, Matthew (University of Copenhagen)

While spaces of incarceration have been the topic of focus of recent studies, what is needed now is sustain attention to material objects related to incarceration and integration with a larger understanding of the traces of ancient Mediterranean incarceration within the archaeological record. To do so, this paper focuses on the small finds and non-architectural aspects of incarceration within a certain city over a select period of time. Specifically, it considers the finds related to the practices and cultural conceptions of incarceration from Maresha, a town located in the Judean mountains ca. 2 kilometres southeast of Beit Gubrin. The finds from Maresha have been dated from the Hellenistic period up through the 2nd century CE and include bronze figurines to terracotta dolls to prisoner petition inscribed on a limestone slab. As such, they provide the opportunity to consider a variety of ways in which incarceration left its mark on the material record from a particular place over a span of several centuries. The paper will situate the finds in relation to other prisons or sites of incarceration and other visual culture in the region.

6 AGENS CURAM CARCERIS. LINKS BETWEEN THE FRUMENTARII OF THE ROMAN LEGIONS AND THE CARCERAL SYSTEM IN THE ROMAN EMPIRE

Bargfeldt, Niels (University of Copenhagen)

The paper undertakes to trace the role that the legionary frumentarii could play in the Roman carceral system. By looking in depth at their role within the system it is possible to address issues related to prison personnel in general.

In the literary sources we often find references to prison personnel as supporting actors in the main storyline. And from excerpts from later law texts, we know of some of the tasks they were assigned to perform and the punishment that negligence or outright breach of rules could lead to. Present representations of prison personnel in the past regularly cast them as grim and boorish men that are often sadistic and are inclined to accept bribes. Even though the evidence for prison personnel is sparse considering the size of the Empire, and the accessible sources are eclectic, the overall picture represented is much more heterogeneous than this stereotypical characterization. The frumentarii of the legions played a variety of roles that were not directly linked to incarceration. And the main scholarly interest has been focused on their assignments as police agents and carriers in the service of both the emperor and the provincial governors. However, epigraphic and literary sources hint that they could be tasked with not only hunting down fugitives and relaying messages, but also with the transportation of prisoners. The evidence shows a link between the prison personnel and the much better-known cadre of the emperor's and the governors' administrators and agents.

1023 CONNECTING THROUGH VITREOUS MATERIALS: MULTIDISCIPLINARY APPROACHES TO MEDITERRANEAN NETWORKS IN THE 2ND-1ST MILLENNIUM BCE

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Loncaric, Valentina (HERCULES Laboratory, University of Évora) - Bettineschi, Cinzia (Department of Classical Archaeology, University of Augsburg) - Koch, Leonie (Institute of Prehistoric Archaeology, University of Cologne) - Oikonomou, Artemios (Science and Technology in Archaeology and Culture Research Center, STARC, The Cyprus Institute) - Angelini, Ivana (Department of Cultural Heritage: Archaeology and History of Art, Cinema and Music, University of Padova)

Session format: Regular session

Vitreous materials, including glazed stones, faience (and glassy faience), Egyptian blue and glass, played a significant role in early human history, and were some of the oldest brilliantly coloured, artificial materials. Current studies of this fascinating material continue to diversify and focus on numerous aspects and avenues of research, such as provenance, working techniques, chemical compositions, as well as cultural contacts and trade and exchange networks galvanized by glass.

With this session, we hope to encourage interdisciplinary discourse on glass from the second and first millennium BCE, contribute to a deeper understanding of vitreous materials, and help develop directions for future research. Spanning a wide geographical and chronological range, this session will focus on new finds, compositional changes, technological advancements, and changes in glass production during this period, extending to their social implications, such as consumption, exchange and contacts facilitated by these colourful artifacts. We are especially interested in contributions related to the ancient Mediterranean and Eurasia during the 2nd and 1st millennium BCE, before the introduction of glass blowing.

We invite scholars, researchers, and experts in the field of archaeology, archaeometry, material science, and related disciplines to contribute their insights, findings, and methodologies including (but not limited to): novel technological studies, experimental replications, typological studies, presentation of specific collections, archaeological contextualization and chronology, theoretical explorations, use/reuse/recycling, provenance studies, and other interdisciplinary research.

ABSTRACTS

1 UNDERSTANDING SPANISH VITREOUS MATERIALS: ARCHAOMETRIC INVESTIGATION OF BRONZE AGE AND EARLY IRON AGE BEADS FROM THE IBERIAN LEVANT

Bettineschi, Cinzia (Department of Classical Archaeology, Augsburg Universität (Germany)); Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice (Italy) - García Atiénzar, Gabriel (University of Alicante (Spain)) - Barciela González, Virginia (University of Alicante (Spain)) - Hernández Pérez, Mauro S. (University of Alicante (Spain)) - Lorrio Alvarado, Alberto (University of Alicante (Spain)) - Graells i Fabregat, Raimon (University of Alicante (Spain))

This contribution will present the results of the project ArGART, funded by the Rakow Grant for Glass Research of the Corning Museum of Glass (USA). This collaborative research marks the launch of the first systematic archaeological and archaeometric study on vitreous materials from the Bronze Age and early Iron Age in the Levant region of Spain.

Approximately 35 beads and perfume containers for a total of ca. 43 samples coming from 7 different sites dated to the 2nd and early 1st millennium BCE underwent a multi-analytical protocol that combined morphometric, textural, and chemico-mineralogical analyses. Additionally, typo-chronological, and spatial investigations were used to diachronically quantify the distribution of these objects and highlight how their recipes vary over time.

Based on our preliminary results, we documented the very first recognized mixed alkali (LMHK) glassy faience in the Iberian Peninsula at the El Amarejo site, even though the predominant recipe for the oldest Spanish glasses is always plant ash (HMG). Natron glasses (LMG) appear only later on, during the local Final Bronze Age (10-9th century BCE) and show, at first, the Fe-rich, and the dark blue Al-Co variants that are already testified in numerous beads from European and Mediterranean contexts dated from the 10th to the 8th century BCE. During this same period, we can assign the earliest appearance of an Egyptian blue bead in Western Europe/Mediterranean at the site of Peña Negra.

From the 8th to the 6th century BCE, the compositions stabilize towards the standard natron glass, but peculiar black and red faience beads can be found associated with the classic blue occurrences, again suggesting strict and direct connections with the eastern Mediterranean.

2 OPAQUE AND TRANSPARENT GLASS BEADS FROM COLCHIS IN THE 1ST QUARTER OF THE 1ST MILLENNIUM BC (EVIDENCE FROM TSAISHI CEMETERY)

Vachadze, Gvantsa (Georgian National Museum)

This research is the introductory study of the appearance and intensification of glass in Colchian Culture and is based on the artefacts found between 2003 and 2007 years in Tsaishi cemetery, located in Samegrelo, western Georgia.

Before the 1st millennium BC, vitreous materials are registered in small quantities in the archaeological records of Western Georgia. Meanwhile, the discovery of transparent glass items or glass vessels is completely uncharacteristic. From the 8-7th centuries BC, the rise in the quantity of opaque and transparent glass jewellery in Colchis is best illustrated in the assemblages found in the burial pits N1 and N2 at Tsaishi.

At this stage, the study aims to shed light on previously unknown glass jewellery items from Colchis by representing beads' typological features and giving a thorough examination of the stylistic parallels in order to demonstrate similarities and/or differences between the glass products in Colchis and in other regions.

Some of the glass artefacts have local parallels, while others, such as zoomorphic samples (bird pendants), have no morphological analogues and find stylistic ties in Greece (Rhodes, Euboea), Levant, Egypt, and in central and northern Italy (Bologna, Vetulonia, Campania..etc). Part of the assemblage appears to be unique, namely the opaque anthropomorphic beads.

The future goal of the research is to study the chemical composition of 41 opaque and transparent glass beads from Tsaishi, using LA-ICP-MS. Compilation of the laboratory and archaeological studies will provide better founded assessment concerning Colchis' position in the processes related to the circulation of glass and in general, ancient trade/exchange relations, especially with the Middle East and the Aegean.

3 FROM THE MEDITERRANEAN MARKET TO THE HOUSE IN OLBIA PONTICA: SPATIAL PATTERNS OF THE DISTRIBUTION OF CORE-FORMED GLASS VESSELS

Kolesnychenko, Anzhelika (Institute of Archaeology of National Academy of Sciences of Ukraine)

The current methodology of recording archaeological finds allows us to raise the problem of the spatial distribution of core-formed glass vessels within large archaeological complexes, such as the Northern Black Sea city of Olbia and the agricultural area of the polis, as well as beyond in the VI – I c. BCE.

The collection from Olbia includes about 300 items. In other sites of the Lower Southern Buh region, there are only a little more than 20 vessels, 16 of which were found directly in Borysthène (Berezan Island). Vessels from Olbia comprise of almost every significant typological kind of such vessels known in the Mediterranean basin. Only Panticapaeum has a similar variety of vessels in the North Pontic region. In Olbia core-formed glass vessels were found in the following contexts: funeral, temple-sacral, public and residential. Public contexts refer to agora objects. Finds in the residential contexts are rare. The vessels were found in the three temene and there are more finds here than in public or residential contexts. The glass vessels were put into burials of Olbians from VI up to I century BC.

The set of vessel types in Olbia differed from those in other Northern Black Sea cities not only in the number of types but also in their selection. For example, Panticapaeum has no fewer types than Olbia, but the sets of types are different. Thus, the diversity of core-formed vessels has the potential to reveal the trade relations of the ancient Greek city. We illustrate this by constructing networks of archaeological similarity for core-formed vessel finds from the Black Sea region and from the Mediterranean, placing Olbia's ego-network in a broader context.

4 INSIDE EARLY IRON AGE FASHION: THE MEDITERRANEAN HEART OF GREAT STEPPE GLASS CUBIC BEADS

Nykonenko, Dmytro (Università degli Studi di Torino) - Yatsuk, Oleh (Università degli Studi di Torino) - Gulmini, Monica (Università degli Studi di Torino)

Early Iron Age glass beads are a powerful indicator of the development of glass-working technology, trade and cultural interactions between different areas and tribes. Glass beads were relatively inexpensive, but still valuable and desirable jewellery, easy to transport and capable of infinite creative expression by their makers. Despite the enormous variety of shapes, colours and decorations, glass beads tended to repeat themselves over time. On rare occasions, however, completely new types of beads appeared and spread over vast areas before disappearing forever after a relatively short period of use. Such vivid traces of ancient fashion include cubic beads decorated with chevrons, which archaeologists have found from the Vistula Basin in the west to the Ural Mountains in the east. The area of distribution of these decorations is about 2 million sq. km. They are found in the monuments of different archaeological cultures, but they are always reliable chronological indicators of the 4th century BCE. The production workshops of these beads are still unknown, but it is generally accepted that they originated from the northern Black Sea region.

Starting from a Scythian burial site on the island of Khortytsia in Zaporizhzhia (modern Ukraine), the authors have carried out a comprehensive study of beads of this type, involving a large interdisciplinary team of researchers. Photogrammetry and micro-CT scanning were used to reconstruct the technological stages of bead production, their sequence and characteristics. The study of the samples by LA-ICP-MS, XRF, FORS, μ -Raman and μ -XRD allowed us to determine the elemental composition of the beads, their colourants and opacifiers. The overall results support the idea that glass beads can be divided into two chrono-compositionally distinct groups that overlapped during the 4th century BCE. It was imported from the eastern Mediterranean, one part from Egypt, the other from the Levant.

5 CONTINUITY OR CHANGE? AN IN-DEPTH ANALYSIS OF CORE FORMED GLASS FROM CENTRAL GREECE

Oikonomou, Artemios (The Cyprus Institute; Institute of Nuclear and Particle Physics, NCSR Demokritos) - Oikonomidis, Stavros (Arcadia University, Glenside, USA; Albanian Archaeological Project at Prespes) - Skoumi, Nelli (Ephorate of Speleology and Palaeoanthropology, Athens, Greece)

Glass, one of the latest pyrotechnological products invented by man, has been used in the form of beads and minor decorative objects since the 4th millennium BC. The earliest glass vessels were manufactured with the core forming technique in Mesopotamia and Egypt during the second half of the 2nd millennium BC (16th-15th c. BC).

The spread of the core-forming technique resulted in a large number of glass vessels produced in the Mediterranean area during the 1st millennium BC. The so-called Mediterranean core formed bottles, which were manufactured in three successive industries between the mid-6th c. BC to the beginning of the 1st c. AD, termed as Mediterranean Groups I, II and III, respectively, circulated extensively all over the Mediterranean.

Numerous glass objects, including a substantial number of fragments from core-formed vessels, were discovered during various excavation seasons in Cave Coroneia (a well-known panhellenic sanctuary operating from Late Bronze

Age to the 2nd century CE), in Boeotia, Central Greece. The fragments cover the three manufacturing industries and belong to Groups I, II and III. The assemblage was investigated using various analytical techniques in an effort to understand changes or/and continuity among the three periods of manufacture and give insights about the technological choices of the glassmakers and the provenance of the raw materials and hence the glass itself.

6 STRINGING A STORY: GLASS ASSEMBLAGES FROM ZAKOTORAC AND NAKOVANA BURIAL MOUNDS (PELJEŠAC, CROATIA)

Loncaric, Valentina (HERCULES Laboratory, University of Évora; IN2PAST Associate Laboratory, University of Évora; Department of Earth and Environmental Sciences, KU Leuven) - Perkic, Domagoj (Dubrovnik Museums, Archaeological Museum) - Dizdar, Marko (Institute of Archaeology) - Potrebica, Hrvoje (Faculty of Humanities and Social Sciences, University of Zagreb) - Costa, Mafalda (HERCULES Laboratory, University of Évora; IN2PAST Associate Laboratory, University of Évora) - Degryse, Patrick (Department of Earth and Environmental Sciences, KU Leuven)

Southern Dalmatia during the 1st millennium BCE is a melting pot of cultural influences from the Adriatic (Dalmatian, Liburnian, Iapodean), the western and central Balkan Interior (Glasinac), and the Mediterranean (S Italy and the Aegean). Recent archaeological investigations of Iron Age burials on the Pelješac peninsula (Croatia) yielded over 500 glass beads and pendants, as well as metal and amber objects and painted pottery testifying to intense cultural contacts between Southern Dalmatian communities and the wider Mediterranean during the Iron Age. The explored graves were used for multiple burials, sometimes containing over a dozen individuals of all age groups. The communal nature and the continuous use of burial mounds at Nakovana and Zakotorac, as well as subsequent robbing in some cases, resulted in a culturally mediated loss of information about how glass beads were used as part of the funerary attire, who they belonged to, and whether there were any noticeable patterns to how they were combined together.

This work puts forward a question of if (and how) integrating multiple approaches – typology, traceology, and glass composition – can help fill the knowledge gaps arising from depositional context and string a coherent narrative from disjointed elements. A working typology based on morphometric attributes and manufacture techniques serves to present an aspect of the aesthetics and visual identity of South Adriatic communities and compare it to neighbouring regions. The typological overview of the material was used to design a research strategy and make informed decisions regarding sampling for archaeometric analyses.

7 FROM SOUTH TO NORTH? MORAVIAN HALLSTATT GLASS: ORIGIN, COMPOSITION AND PRODUCTION

Melichar, Petr (Palacký University Olomouc) - Golec, Martin (Palacký University Olomouc) - Golec Mírová, Zuzana (Charles University Prague) - Kučera, Lukáš (Palacký University Olomouc) - Kučerová, Pavla (Palacký University Olomouc)

Glass in its natural form enticed human interest since the oldest times and the secret of its production was unraveled as early as the Bronze Age – but it was not until the Iron Age that glassmaking saw its extraordinary development and spread of glass products across regions. Czech project “From South to North? Moravian Hallstatt Glass: Origin, Composition and Production” tracks the bloom of Hallstatt Period glassmaking in relation to Moravian territory (Czech Republic), primarily based on the study of the so far biggest known collection of Hallstatt Period glass north of the Alps, coming from the Býčí skála Cave sanctuary (575–450 BC), containing elite burials. This collection, comprising more than 4500 pieces of glass beads, supplements reference glass material from selected Moravian hoards and graves. Methodologically, we followed a complex approach, taking into account the wide range of analytical possibilities that vitreous materials offer. Therefore, beside optical description, typology and analogies, we also work with results of SEM/EDS measurements, opening topics of chemical composition, type and possible provenance of glass. Acquired data are compared with contemporary finds from regions of Bohemia, Slovenia, Poland, Italy and the question of the origin of Moravian glass is tested. The material is likewise commented on in relation to the Amber Road, of which Moravia was an integral part. The role of glass as a counter-value of southern centres for goods of northern origin, long-distance trade of Hallstatt Period Moravia with some glass production centres, based on specific types of beads, as well as the question of possibility of primary glass melting in the Central European context, is discussed.

8 VERUCCHIO CONNECTED. ON SOME IMPORTED GLASS BEADS FROM VERUCCHIO (EMILIA-ROMAGNA, ITALY)

Koch, Leonie (University of Cologne, Germany – Institute of Prehistoric Archaeology)

Verucchio, in the hinterland of Rimini, with its Early Iron Age necropolises has provided many new insights into the Villanovan culture of the Romagna in recent decades. The most recent excavations, carried out by Patrizia von Eles in 2005-2009, provided the opportunity for a personal and detailed archaeological study of the glass bead finds.

Peculiar shapes dating from the mid-8th century B.C., which have no parallels to date, and the specifically Italic shape of the glass bow fibula make local glass processing in Verucchio very likely.

More recent finds include the famous glass bird beads, probably from the Aegean. Other items and a special form of pendant can be considered as imported objects. These forms of jewellery made of vitreous materials belonging to the female sphere are presented and their parallels (known to the author) are given. They complete our picture of the Early Iron Age Emilia-Romagna, which is rather poor in imports, even if direct links with the areas of origin cannot be taken for granted.

9 ETRUSCAN GLASSES FROM FORCELLO DI BAGNOLO SAN VITO (NORTH ITALY): A NEW ARCHAEOLOGICAL AND TECHNOLOGICAL STUDY

Malaman, Elisabetta (University of Padua) - Angelini, Ivana (University of Padua) - Rapi, Marta (University of Milan)

Considering Etruscan materials and productions, glass remains one of the less explored areas. Until now, scholars have primarily focused on typological and decorative studies of Etruscan glasses, leaving information on the composition and origins of glass relatively scarce. To enhance our understanding in this field, we have chosen to investigate 28 glass beads and 4 fragments of unguentaria from the Etruscan site of Forcello di Bagnolo San Vito (Mantua, Italy). We conducted analyses on both the glass body and coloured decorations, totalling 56 samples. The analysed set include the majority of finds from archaeological excavations, and few objects from archaeological surveys. The materials can be dated between the end of the VI century BC and 380 BC, corresponding to the different phases of the Forcello site. This research aims to reconstruct their manufacturing techniques, identify the raw materials and colouring agents used, and discuss the possible provenance of the glass. The initial phase of our work involved an examination of the artefacts through stereomicroscopy. This step aimed to assess the conservation state and identify production markers. While the vessels can be categorized within the Mediterranean core-formed groups, their fragmentary state renders them typologically unclassifiable. The beads primarily fall into the annular and eyed types, with bodies produced using the winding technique while the eyes exhibit various creation methods. The studied artefacts underwent micro-sampling, and the resulting glass fragments were comprehensively characterized from a chemical, mineralogical, and textural perspective. Chemical characterization of the glass phases and crystalline inclusions was achieved through the application of optical microscopy, SEM-EDS, EPMA, and/or LA-ICP-MS analyses. Micro-Raman was employed to characterize the mineralogy of opacifiers and remains of raw materials. The obtained results will be discussed in relation to data available in the literature concerning coeval glass objects with comparable typologies.

10 CONTEXTUALISING VITREOUS MATERIALS IN ETRURIA. THE CASE STUDY OF THE MONTE ABATONE NECROPOLIS

Briesack, Christian (University of Bonn)

From the Orientalising period onwards, the Etruscans buried their dead with a wide range of grave goods, including jewellery, precious vessels and other valuable objects made of glass and related materials. These burials, which belonged to the upper class of the society, were a constant reminder of their wealth and power. Vitreous artefacts were also found at the Monte Abatone necropolis of the famous Etruscan city of Cerveteri, which has been under investigation by an international cooperation of several universities together with state authorities for years. In the period between 2018 and 2022, excavation campaigns were carried out on site by the group. This paper will present some vitreous materials from the necropolis, based on the excavation results of the University of Bonn, which is involved in the cooperation. The archaeological finds range from the well-known glass beads to spiked vessels to pendants and amulets made of faience. In a second step, these objects will be analysed in the context of the necropolis as a whole. Having done that, they finally need to be compared with materials found in the other Caeretan burial sites, like Banditaccia, Laghetto, Bufolareccia and Sorbo. This is necessary to get an overall interpretation of glass and related materials at Monte Abatone.

1024 UNDERSTANDING BEHAVIOURAL CHANGES THROUGH MATERIAL STUDIES - ADAPTATION AND SOCIAL COMPLEXITY OF THE HOMO SAPIENS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Petrović, Anda (University of Belgrade) - Vinet, Alice (Aix-Marseille University; UMR 7269 LAMPEA) - Debels, Pauline (UMR 8215 Trajectoires) - Macane, Aija (University of Helsinki; University of Latvia)

Session format: Regular session

The aim of the session is to understand the adaptations and traditions of prehistoric groups from the Paleolithic to the Bronze Age by qualifying and quantifying behavioural changes through material studies. The study of the complete

chaîne opératoire of an artefact, from raw material procurement to production, use and discard brings significant information that contribute to the understanding of the relationships within and outside the community.

The geo-chronological frame of the session is intentionally broad to tackle short and long-term lifestyle changes by studying the biographies of the tools used daily in prehistory, whether the changes are economical, sociological, environmental, and/or a matter of survival. The methodological frame of the session encompasses raw material procurement strategies, production, use-wear, technological and typological studies that question the knowledge transfer and adaptability of the past populations. The session welcomes papers based on both archaeological and ethnographic records that address the activities which are considered to develop a social connection within the community, such as subsistence or craftsmanship with broader discussion on their influence and development of social skills. The goal is to address the reasoning behind certain processes, such as the unconventional role of flint tools and changing relationships towards animal remains in funerary rites of hunter-gatherer communities of NE Europe, or, for example, how hunting was appraised in Chalcolithic of Central Anatolia when it became nonessential for survival.

ABSTRACTS

1 IMPORTS AND OUTCROPS: OBSIDIAN PROCUREMENT AND THE EVOLUTION OF HOMO SAPIENS BEHAVIOR IN THE LATE PLEISTOCENE HORN OF AFRICA

Smith, Benjamin (CEPAM, Université Côte d'Azur) - Johnson, Lucas (Far Western Anthropological Research, Inc.) - Brandt, Steven (University of Florida)

The emergence of hominin behavioral complexity in Africa during the Middle and Late Pleistocene is associated with increased trade in exotic raw materials, increased foraging ranges, and the development of new settlement and material procurement strategies. Identifying the scale and directionality of stone procurement in the Late Pleistocene Horn of Africa is essential if we are to explore the emergence and dispersal of Homo sapiens during this time. However, we still need more well-dated sites and identified obsidian sources. Here we characterized forty-two obsidian samples from the Baantu obsidian source in southwestern Ethiopia, including 25 outcrop samples and 17 surface artifacts, using portable X-ray fluorescence spectroscopy. We then compared these source data to 116 obsidian artifacts from Mochena Borago Rockshelter. Results indicate that at least three geochemical source clusters are represented at the Baantu source: one derived from sampled outcrops and two deriving from as-yet unknown source locations. Comparing these data to obsidian artifacts at Mochena Borago excavated from levels dated to >50 ka and ~44 ka BP, early levels dating to > 50 ka preserve obsidian from as many as six as-yet unidentified sources, while Baantu obsidians were in the minority. By ~44 ka cal BP Mochena Borago occupants procured most if not all of their obsidian from the Baantu source. The occupants of Mochena Borago Rockshelter clearly adapted to periods of major ecological and social change during the Late Pleistocene through their procurement and use of stone raw materials. The data we present here are part of a growing body of research that fills a gap in our spatial and temporal knowledge of stone procurement during this period in Homo sapiens behavioral evolution.

2 NEW INSIGHTS INTO THE LITHIC ASSEMBLAGES FROM BURIAL CONTEXTS AT ZVEJNIEKI, LATVIA

Petrovic, Anda (Department of Archaeology, Faculty of Philosophy, University of Belgrade) - Macane, Aija (Department of Cultures, University of Helsinki; Institute of Latvian History, University of Latvia) - Nordqvist, Kerkko (Helsinki Collegium for Advanced Studies, University of Helsinki) - Zagorska, Ilga (Institute of Latvian History, University of Latvia) - Edmonds, Mark (Department of Archaeology, University of York) - Little, Aimee (YEAR Centre, Department of Archaeology, University of York, PalaeoHub)

This paper presents new results, and offers preliminary interpretations, of a recent functional study of lithic artefacts from burial contexts at Zvejnieki, carried out as part of the AHRC-funded Stone Dead Project. Zvejnieki is one of the largest Stone Age hunter-gatherer burials grounds in NE Europe, located along a drumlin on the northern shore of Lake Burtieks in northern Latvia. According to the radiocarbon dates cemetery was used between 7500 – 2500 cal BC. Through a combination of geology, technology, trace wear analysis, and spatial/contextual studies, we have been able to identify patterns in the choice of objects placed into the graves, some of them used, others made specifically for burial. By combining this information with biographical data for the associated human skeletal remains, it becomes possible to identify the kinds of links that were made between specific categories of artefact and different kinds of people during Baltic Stone Age mortuary rites and rituals.

3 PRODUCTION AND USE OF ANIMAL TOOTH PENDANTS IN THE STONE AGE SETTLEMENT OF ZVEJNIEKI II, NORTHERN LATVIA

Macane, Aija (Institute of Latvian History, University of Latvia; University of Helsinki) - Zagorska, Ilga (Institute of Latvian History, University of Latvia)

The well-known Zvejnieki cemetery contains one of the largest collections of osseous artefacts from hunter-gatherer burial contexts in Europe. Numerous studies have examined various aspects of personal ornaments, tools and animal remains from burials. However, the nearby settlement materials of Zvejnieki II have not received similar attention. This paper presents new study on the collection of animal tooth pendants from the settlement context, which was carried out in the project "Skills in synergy, crafts in context: an integrated study of eastern Baltic Stone Age technologies" at the Institute of Latvian History. Osteological, technological, and contextual analyzes provide new insights into animal species, production, and use of pendants in the settlement. The results show differences between the production of tooth pendants from settlement and cemetery contexts. This is an important contribution to better understanding human choices regarding the manufacture and use of pendants, e.g., the selection of certain animal species and technological solutions used in the Zvejnieki settlement compared to the cemetery.

4 WHAT STORIES DO THE DECORATED HUNTER-GATHERER OSSEOUS TOOLS TELL? RECENT RESEARCH AND RESULTS FROM LITHUANIAN TERRITORY

Rimkus, Tomas (Vilnius Academy of Arts, Vilnius, Lithuania; Institute of Baltic Region History and Archaeology, Klaipėda University, Klaipėda, Lithuania)

Bone and antler artefacts are frequently found in Lithuanian territory in wetland sites and as stray finds. In recent years, their AMS 14C dating and technological studies have provided new insights into the knowledge of Final Palaeolithic, Mesolithic and Neolithic organic tools production. As these studies have shown, some of the artefacts are decorated with various types of different or sometimes similar ornaments. Most of them form simple or complex, extended geometric compositions. In past Lithuanian archaeological works, these artefacts were mainly treated from the ritual perspective of a hunter-gatherer symbolic worldview. For some reason, the tool itself and its technological aspects were not discussed further. However, the tool itself and its different technological aspects could provide more data about the ritual in the past, changes in human behaviour and adaptation. In 2024, a new research project was initiated focusing on decorated bone and antler artefacts found on the territory of Lithuania. It aims to shed light on the aspects of tool and ornament preparation, their type and dating, and the determination of the raw materials. Microscopic, 3D scanning, AMS 14C dating and ZooMS methods were used. These integrated methods have provided new data on hitherto little studied ornamented organic artefacts. This paper will therefore aim to present and discuss (1) the aims of the project, (2) the studied objects and (3) the results of the complex research.

5 QUANTIFYING CULTURAL CHANGE THROUGHOUT LITHIC MATERIAL STUDIES: THE CASE OF MIDDLE NEOLITHIC IN DEHESILLA CAVE (SOUTHERN IBERIAN PENINSULA)

Barrera-Cruz, María (University of Valencia) - García-Rivero, Daniel (University of Seville)

The Neolithic includes a broad spectrum of human behaviors. In the Iberian Peninsula, farming groups arrived in the first half of the sixth-millennium cal. BC, and the spread of new populations continued after that. The highly diverse material culture of the Neolithic has been interpreted as a reflection of multiple origins and as the regionalization that followed. That cultural variability is mostly explored via pottery studies; in Southern Iberia, during the early Neolithic, cultural traits shared with other regions, such as impressed and incised wares, coexisted with others specific to the area, such as the bright red almagra pottery. Over time, studies detected generalized changes in the material record (c. second half of the fifth millennium), e.g., in the decoration dynamic in the pottery assemblage, in the size average of blade production, or the faunal and botanical record. In addition to the abovementioned changes, there are further particularities, such as the Middle Neolithic A (MNA) documented in Dehesilla Cave. Within a broad archaeological sequence that includes occupational events from several Neolithic phases (c. 5600-3800 cal BC), Dehesilla presents the MNA record dated between c. 4800-4500 cal BC, seemingly different from the assemblage recovered from that found for the area's previous, and later phases, as well as contemporary assemblages. Along with introducing engraved decoration in the material culture and changes in the economic pattern, we detected some particularities in the lithic record. Nevertheless, to what extent does the lithic technology accompany the particularities already known from the MNA of the Dehesilla cave? Here, we introduce an advance of the comparative study between the lithic assemblage recovered for MNA and the toolkit used by human groups in different Neolithic phases, thereby completing the information about apparent changes in the lifestyle of prehistoric human groups between the sixth and the fourth-millennium cal. BC.

6 CELT PRODUCTION PROCESSES AND LOCI IN NEOLITHIC GREECE: THE CASE OF THE THRACIAN SITE OF MAKRI

Stroulia, Anna (University of Southern Indiana) - Bekiaris, Tasos (Aristotle University of Thessaloniki) - Melfos, Vasilios (Aristotle University of Thessaloniki) - Stergiou, Christos (Aristotle University of Thessaloniki)

Celts represent one of the most studied macrolithic (i.e., ground stone) types from Neolithic Greece. Reports offering various degrees of detail are available for more than 25 assemblages. Due to archaeological biases, however, these assemblages are not evenly distributed geographically. Most derive from the regions of Macedonia and Thessaly, with other areas represented minimally or not at all. Equally important, light has been shed on raw material types and acquisition systems, manufacturing techniques, aspects of use, practices of discard, as well as non-utilitarian dimensions. Yet, very little is known about the whereabouts of celt production. In this contribution, we attempt to address both gaps by turning our attention to the region of Thrace in the northeastern part of the country and focusing on the 200 or so celts excavated at the Middle-Late Neolithic site of Makri. We discuss these tools' lithologies and chaînes opératoires, revisit a structure identified by the excavators as a celt workshop, bring in relevant data from other sites, and, last but not least, deconstruct the celt workshop concept itself.

7 ADDRESSING SOCIAL BEHAVIOR IN NEOLITHIC ANATOLIA THROUGH TECHNO-FUNCTIONAL STUDY OF CHIPPED STONE TOOLS

Vinet, Alice (Aix Marseille University; UMR 7269 Lampea)

Beginning in the Late Neolithic (ca. 6500 BC), changes took place in central Anatolia that affected numerous aspects of daily life among local communities. These changes demonstrate increased social competition as expressed in funeral practices, craft production, human and pastoral mobility, and social interactions. The lithic industry, however, does not seem to be impacted by these upheavals. Central Anatolia, with its widely distributed obsidian sources, is a key region for investigating community development through the lenses of raw material exploitation, economy, and technology.

This communication will highlight the behaviors related to the production, use, and abandonment of the obsidian industry of Tepecik Çiftlik (Cappadocia) and Çatalhöyük West (Konya plain). The results contribute to the definition of two cultural groups in central Anatolia between 6000 and 5500 calBC by providing new data on the production and use of obsidian from domestic and ritualized contexts.

A diverse range of activities occurred at both sites, in which the work of minerals, plants and hide played a major role. Certain endeavors, like hunting, transcended mere survival needs, acquiring social and symbolic significance. This evolution in the role of hunting reveals the complexity of social relations within Anatolian Neolithic communities, highlighting their resilience through the transformation of their collective identity.

8 ECHOES FROM THE CAVE: EXPLORING THE LIFE-HISTORIES OF MACROLITHIC ARTIFACTS FROM LATE NEOLITHIC DRAKAINA CAVE, KEPHALONIA ISLAND, WESTERN GREECE

Bekiaris, Tasos (Aristotle University of Thessaloniki)

Drakaina Cave is a small, karstic cavity located on the steep slopes of Poros Gorge at the SE part of Kephallonia Island, Ionian Sea, Western Greece. Excavations at the site revealed a complex cultural sequence, dated both to the historic (late 7th – early 2nd centuries BC) and prehistoric periods (Early Helladic – Late Neolithic, circa mid-6th – late 3rd millennium BC). Late Neolithic deposits comprise the bulk of the prehistoric sequence of the site (circa 5500 – 3700 cal BC). They have yielded several architectural features (e.g. lime-plastered floors, hearths) and rich datasets of organic (e.g. terrestrial and sea faunal remains, charred woods, seeds) and inorganic finds (e.g. pottery, ornaments, chipped stone and macrolithic implements). The macrolithic assemblage of Drakaina Cave comprises nearly 470 implements, of a rather conserved typology, that included grinding tools, percussive tools, and a few stone celts.

In this paper, we explore the life histories of the macrolithic implements from Drakaina Cave. Through the detailed study of their technological attributes, mainly their raw materials, manufacture and curation patterns, macroscopic use-wear and discard practices, we attempt to interpret the presence of the macrolithic implements in the Cave and comprehend the character of the activities, which they have supported. Based on the current evidence, it is suggested that only specific types of macrolithic implements were brought to Drakaina Cave, in order to be used for short time periods, within the context of specific tasks, and that their life cycles ended upon the completion of these tasks. Those visits may have had the character of small group gatherings of a symbolic and/or social character.

9 ECHOES OF NEOLITHIC LIFE: DECIPHERING FLINT ARTEFACT BIOGRAPHIES FROM CAUSEWAYED ENCLOSURES

Bye Jensen, Peter (Vejle Museer)

This paper centres on the depositional practices at Neolithic causewayed enclosures, utilising use-wear analysis, and surface modifications on flint tools to construct artefact biographies that illuminate activities and practices within these monuments. By integrating use-wear analysis with a detailed examination of the flint tools surface modifications, one can decode a fossilised record of these artefacts—from procurement and manufacture to use and eventual discard or deposition. This approach reveals not only the functional aspects of tool use but also the sheds new light on depositional practices Neolithic societies.

Focusing on a selection of assemblages from causewayed enclosures from southern Britain and southern Scandinavia, tracing the biographies of flint tools to understand their roles and how they could have become artefacts in Neolithic rituals practices and social interactions. The study employs a robust methodological framework, combining microscopic analysis of wear patterns with contextual archaeological evidence, to interpret the surface modifications as narratives of past human behaviour.

This paper contributes to a nuanced understanding of Neolithic causewayed enclosures, showcasing how the detailed narrative of flint artefacts' life biographies can enrich our understanding of complexities and activities of Neolithic societies.

10 UNDERSTANDING SOCIAL RELATIONS OF BRONZE AGE COMMUNITIES IN THE CARPATHIAN BASIN: CERAMIC PETROGRAPHIC ANALYSIS IN THE MAKLÁR MICROREGION (NE HUNGARY)

Mengyán, Ákos (Hungarian National Museum; University of Miskolc)

The primary step of chaîne opératoire of pottery production is the collection and transformation of the clay material that includes the selection of the raw material, tempering, and paste preparation. These are defined by various social and cultural habits that can refer to the social identity of its producer. Ceramic petrographic analysis can help us to identify the raw materials and fabric techniques and to determine the provenance and the type and quantity of the temper of the raw materials as well. Therefore, the analysis of technological choices, including raw materials and fabric techniques, can enable us to assess the nature of social relations between communities.

On the Northern Great Hungarian Plain, two cremation cemeteries are known 1.5 km from each other in the Maklár microregion (North-Eastern Hungary), dated by relative chronology around 1500–1300 BC. On Maklár-Kospérium, 121 and on Maklár-Nagyret II., 210 burials were excavated that can be assigned to the Tumulus culture. In its development, small-scale migration and the evolution of local population might have played an important role in this area. Thus, territorial groups can be distinguished based on ceramic typology, which might have their roots in the preceding regional cultures.

Besides typological and stylistic analyses, this microregional research focusing specifically on the raw material preparation and fabric techniques of the pottery grave goods, applying thin section petrography. The aim of this study is to explore patterns in the raw materials and tempering that allows us to identify and understand social connections within and between the two distinct and contemporaneous Maklár cemeteries. Furthermore, the relationships between raw material selection and typological and stylistic analysis offer a unique opportunity to shed light on to the social relations of the Maklár Bronze Age communities.

11 ASSESSING 100 YEARS OF EVOLUTION OF FOOD PRACTICES IN A SENEGALESE VILLAGE, THROUGH THE USE-WEAR ANALYSIS OF THE POTTERY ASSEMBLAGE

Debels, Pauline (LabEx DynamiTe - UMR 8215 Trajectoires; ARCAN - University of Geneva) - Vieugué, Julien (UMR 8068 TEMPS) - Sall, Moustapha (Cheikh Anta Diop University) - Mayor, Anne (ARCAN - University of Geneva)

Middens are valuable study subjects for archaeologists. While objects made of ceramic, fauna, lithic, metal or plastic bring significant information on the state and evolution of a material culture, ecofacts contribute to the reconstruction of the environment, as well as the fraction humans choose to take and transform from that environment.

As part of the SNF Sinergia project Foodways in West Africa, a midden spanning throughout the entire 20th century has been archaeologically investigated in the village of Edioungou (Lower Casamance, Senegal). This contribution offers the results of the functional analysis of the ceramic assemblage (MNI 365) with the aim of understanding the evolution of the use of pots and subsequently, food habits. The method is based on the macroscopic (naked eye and stereomicroscope) observations of addition traces (sot, carbonized residues, carbonate formation...), subtraction wear (abrasions, carbonate dissolutions...) and modification of the pot surface or structure (oxydisation, fractures, cracks...)

This study has highlighted different paces of changes. Some pots such as water storage jars show a great continuity because of technical performances, while others, formerly used for a large range of activities from transport to hygiene, have nearly completely disappeared through time in favour of similar shapes made from more efficient material such as plastic, glass and enamelled metal. Some of them have also been simply abandoned following behavioural changes. Different phenomena (performance characteristics, religion, food habits and availability) have driven the evolution of pottery use in Lower Casamance and at different rates. These insights help understand archaeological rhythms of changes and disappearances in pottery shapes.

1027 HOW TO HUNT? HOW TO HERD? NEW APPROACHES TO OLD QUESTIONS ON HUMAN-NONHUMAN/ANIMAL ENTANGLEMENTS

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Windle, Morgan (Kiel University) - Lemke, Ashley (University of Wisconsin-Milwaukee) - Piezonka, Henny (Freien Universität Berlin)

Session format: Regular session

With the expansion of posthumanist approaches in archaeological research, pivotal moments in the human past can be reinvigorated by novel perspectives. Perhaps most prominently, the decentering of human agency has elucidated the dynamic co-production of cultural practices and landscapes that can occur between humans, nonhuman animals, and the environments they share. Such methodologies offer fertile ground for transdisciplinary investigation that may expand our capacity for understanding human-nonhuman pasts. Particularly with regards to questions concerned with hunting and husbandry strategies, niche-construction, and the domestication of animals, the posthumanist turn can offer explanations for specific processes of human-nonhuman relationships beyond traditional behavioral ecology models.

The hunting and herding of animals are often considered in isolation of one another, or as a binary. But what of those societies engaged in both? How can we better understand hunting and/or herding knowledge systems of the past? What sort of insights could be yielded by examining the entirety of the hunting-herding spectrum through a posthumanist lens simultaneously?

This session focuses on theoretical and practical aspects of modeling human-nonhuman animal entanglements, with emphasis on how we understand past human hunting and/or herding strategies. We welcome theoretical, methodological, and case study contributions that reflect the complex relations between human and nonhumans regardless of time and space. Moreover, we are especially interested in the approaches that seek to describe and present cultural landscape transformation through non-anthropocentric frameworks. In order to guide the session, we invite contributions that tackle one or more of the following questions:

- What are relevant environmental, spatial or landscape features, and what roles do they play in the development of human/nonhuman communities and their socio-economic strategies?
- How can complex human-nonhuman/animal entanglements be modelled allowing the application of anthropological theory to archaeological data?
- What tools and approaches provide the data needed for a post-humanist framework?

ABSTRACTS

1 RECONCEPTUALIZING HUMAN AND DOMESTIC ANIMAL ENTANGLEMENTS: ECONOMY, DEMOGRAPHY, AND METHODOLOGICAL CHALLENGES OF SMALL-SCALE PASTORALISM

McClure, Sarah (University of California, Santa Barbara)

Studies of ancient pastoralism in Europe have often centered on efforts to reconstruct domestic animal management systems to assess the economic contributions of having herds. Using basic zooarchaeological techniques such as epiphyseal fusion data and tooth eruption and wear, scholars have reconstructed mortuary profiles of sheep, goats, and cattle, and made inferences about the types of products (meat, milk, wool) herd managers were targeting, along with the scale of production within differing socio-economic and cultural spheres. While many of these studies have provided insights into ancient pastoral practices on large scales, this paper explores the theoretical and methodological challenges posed by this approach for small-scale pastoralism. Using ethnographic and historical accounts, along with archaeological data from Neolithic sites on the Dalmatian coast of Croatia, this study highlights the discord between applied methodologies and their theoretical premises with the nature of the archaeological record and assumptions about the scale, role, and purpose of pastoralist activities within small-scale farming communities. It illustrates the fundamental problem with using mortuary profiles to reconstruct economic contributions in these contexts, and explores alternative methodological approaches to assess the nature, scope, and practice of herding in agropastoral

societies. Ultimately this approach has implications for re-envisioning Neolithic cultural landscapes based on human-animal entanglements and provides incentive to pursue other lines of inquiry for characterizing Neolithic material and non-material interactions.

2 HOW TO HUNT? THE BEHAVIOUR OF ANIMALS AS A GUIDE FOR HUNTERS IN 13TH-14TH CENTURY NORTHERN FENNOSCANDIA

Jääskeläinen, Emilia (Archaeology, University of Oulu) - Salmi, Anna-Kaisa (Archaeology, University of Oulu)

Hunting is about knowing how the game animals behave, what kind of tracks they leave behind and what kind of landscapes they inhabit. In other words, the behaviour of the animals affected the hunter's movement and perception of the landscape. In this paper, we will present a case study from the Finnish Late Iron Age (800-1300 AD) when hunting was still an important way of life for local communities living in the North. Our focus is on two animal species, the European beaver (*Castor fiber*) and the wild reindeer (*Rangifer tarandus*), as these species were identified in the zooarchaeological analysis of animal bone assemblages from a 13th-14th century settlement site called Illinsaari 3, in Ii, Northern Ostrobothnia. With the help of animal ecology, ethnographic analogies, and known historical hunting methods we investigate how these two animals behaved, what kind of tracks and traces they might have left behind, and how hunters perceived these and the landscape when trying to find hunting grounds and prey.

3 INTEGRATING TRADITIONAL ECOLOGICAL KNOWLEDGE IN ARCHAEOLOGY: APPLICATIONS IN THE MODELLING OF HUMAN-RANGIFER INTERACTIONS IN NORTH AMERICA AND NORTHWEST ASIA

Windle, Morgan (Christian-Albrechts-Universität zu Kiel) - Lemke, Ashley (University of Wisconsin-Milwaukee) - Piezonka, Henny (Freie Universität Berlin)

Indigenous epistemologies reveal an intimate immersion in, and deep knowledge of, the nonhuman elements of human habitats. Indigenous cultures worldwide demonstrate the futility in attempting to disentangle humans from the environments they inhabit. Knowledge is instead constructed through transgenerational ecological observations, oral history and narrative, as well as animate interspecies interactions which form the basis for Traditional Ecological Knowledge (TEK). Recent incorporations of Indigenous methods (like TEK) into various branches of anthropology and biology have demonstrated their immense capacity to guide data interpretation and be utilized as a valid scientific method. Despite this, integrations of TEK into archaeological approaches remain on the periphery of the discipline, only applied where archaeologies directly overlap with descendant communities e.g., in Indigenous-led research. These methodologies offer transformative, transdisciplinary opportunities to expand our capacity for understanding human-nonhuman pasts. A key example of this is human-Rangifer relationship research. Rangifer tarandus (reindeer/caribou) have helped shape the complex cultural fabric of both North American and Northern Eurasian societies; however, the intricacies of human-Rangifer systems contradict archetypes of domestication modelling and are not yet easily replicated in a digital space.

This paper will demonstrate how TEK can be integrated by comparatively exploring human-Rangifer relationships across two temporal landscapes: the small-scale reindeer herding amongst modern hunter-fisher communities in Northwest Asia; and the 9,000-year-old legacy of caribou hunting strategies in North America recorded via underwater archaeology. Despite their disparity in time and place, these two studies offer examples of prominent nonhuman agency in the formation of cultural landscapes and show how deep ecological knowledge can shape niche-constructing activities inherent to human-nonhuman relationship dynamics. These case studies attempt to move beyond common behavioral ecology models through the implementation of TEK in collaborative archaeology, relational approaches, and virtual reality modeling.

4 COLLECTIVES ON THE MOVE: EVENKI HUNTERS AND THEIR REINDEER CARAVAN IN THE TAIGA OF EAST SIBERIA AND FAR EAST

Brandisauskas, Donatas (Lithuanian Institute of History)

In my presentation I aim to introduce to how domestic reindeer is perceived by indigenous nomadic Evenki reindeer herders and hunters as individual person with own distinguished characters, responses, physicality rather than mere instinct driven herd animal as it was often seen in studies of hunters and gatherers or pastoralists. These knowledges of diversity of reindeer also help to organize reindeer into caravan successfully performing cargo activities in mountainous taiga landscape. In contrast to the human/animal models stressing the role of autonomy and intermittency of relations with animals in Northern Asia, I aim to show how embodied interactions, intentions and established mutual communication of Evenki and their individual reindeer can be deeply convolved in their joined activities and intentions this way bonding integrity of the human/reindeer social continuum. The presentation is based on my long-term eth-

nographic research among different communities of Evenki reindeer herders and hunters of East Siberia and Russian Far East (Russian Federation).

5 RECREATIONAL HUNTING IN PREHISTORY

Scutt, Win (English Heritage)

We know from ethnological studies that the hunting of animals is not only a subsistence practice but also sometimes a recreational activity. It can be used in rites of passage or as entertainment that brings societies together to share a common experience. The opportunities for competition and excitement are an important incentive for groups from far and wide to gather at certain times of the year. There is good documentary evidence from the Greek Iron Age in the form of the Panathenaic and Olympic Games for festivals that combined sport with religious observance; and evidence for sport in the archaeological record, for example, bull leaping in Minoan Crete and ball games in Mesopotamia. But sporting activities rarely impact on the archaeological record.

This paper will explore the possibility that *Cursus* monuments of the British Neolithic were used as performance areas for sporting activities. When the first *Cursus* was identified by Stukeley in 1723, he decided it was a Roman chariot racecourse. Since then, some 100 *cursus* monuments have been identified in Britain and are dated to c.3600-2900 BCE, in the Early and Middle Neolithic.

What sort of sporting activities and social interaction would such arenas afford? We shall explore whether these activities might have involved animals as sporting performance; which species of animals might have best suited these spaces; how participants and spectators interacted with the activity; and how these performances may have played out. In conclusion, the most likely scenario afforded by the dimensions, topography and resources of *Cursus* monuments is that they were used for deer coursing as a social activity.

6 THE RELEVANCE OF "BEING WILD"? THE 3RD MILLENNIUM BCE IN CENTRAL AND SOUTHERN PORTUGAL

Almeida, Nelson (CHAIA, Universidade de Évora, PT; UNIARQ, Universidade de Lisboa, PT) - Guinot, Catarina (Universidade de Évora, PT) - Ribeiro, Inês (CHAIA, Universidade de Évora, PT) - Basílio, Ana (ICArEHB, Universidade do Algarve, PT)

The southwestern Iberian Peninsula is an area with an important amount of research concerning the 3rd millennium BCE archaeological records, corresponding roughly to the Chalcolithic and transition of the Early Bronze Age. Several major sites are known in this region, some of them with historically recognisable relevance to the extra-regional discussion of this Late Prehistory period.

Different types of sites are known, comprising funerary megalithic and non-megalithic structures and ditched and walled enclosures. Among the most frequently recovered materials, especially at the latter sites, are the zooarchaeological remains. These show the relevance that domesticated animals had to these groups' economic and non-economic spheres. Almost inexistent in some of the zooarchaeological records, while present and even common in others, wild species have also been of importance to economic and other-than-economic behaviours. Isolated or in anatomical connection, animals and animal body parts have been recovered in significant archaeological contexts, such as structured depositions or commensality events. At the same time, they are known in rock art depictions, and their figures or parts are recognised in material culture, as is the case with pottery, loom weights, or figurines.

We present a state-of-the-art zooarchaeological record of the Central and Southern Portuguese territory during the 3rd millennium BCE. This is considered, together with the use of animals, animal body parts, or their representation, to discuss the changing papers that different species add to the scope of human-animal relations.

7 THE LAST HUNTERS FROM THE GUMELNIȚA CULTURE (4500-3900 CAL BC, ROMANIA)

Balasescu, Adrian (Institute of Archaeology, Romanian Academy)

The archaeological investigations conducted over the past three decades within the Gumelnița sites (4500-3900 cal BC), located in the southeastern region of Romania, have shown that hunting activity in the area rises to unprecedented levels for the Neo-Eneolithic. Thus, of the 21 Gumelnița sites studied from an archaeozoological point of view, it can be observed that in at least seven of them, the remains of wild mammals exceed 50%, and in more than half of them the weight of game exceeds 30%.

The remarkable diversity of wild mammals encountered within the Gumelnița environment (21 taxa), allows us to observe that these hunters exploited different environments found near the settlements, which proves the existence of forested massifs, but also open spaces.

In most of the Gumelnița sites, the red deer (*Cervus elaphus*) ranks first in terms of the number of remains, followed by the wild boar (*Sus scrofa*) in only six samples and the aurochs (*Bos primigenius*) with three lots. We note the pres-

ence of the wild horse (*Equus ferus*) with a percentage exceeding 5%. As can be seen, large and very large animals were hunted with preference.

The abundance of meat, but also other products provided by game, suggests, at this stage of the study, a possible specialisation in this activity by some individuals within the Gumelnița communities in different locations, where hunting plays a primary role.

The purpose of this presentation is to capture the evolution of this hunting activity across different tell-type sites, thereby facilitating an observation of societal transformations influenced by various environmental and climatic factors.

8 OF PIGS, FORAGERS AND HERDERS OF THE IRANIAN HIGHLAND

Thomalsky, Judith (German Archaeological Institute)

The Iranian highland counts to one of the origin centers of domestication. Not only the first steps towards husbandry practices but also plant management can be observed in the intermountain valleys of the Zagros range. This process was an indigenous one, and proceeded by local hunter-gatherer communities, including a “transitional phase” that started from around 10.000 BC. In almost all related sites the number of hunted (wild) animals remained relatively high, at least until Neolithic lifestyle was adopted throughout the Iranian plateau around 6000 BC. While it is clear that in particular the goat was the focus of early animal management along the Zagros fringes, domestic sheep appeared considerably later and most probably during a second wave of domestication in W-Asia. Another important group of early domesticates are pigs. Possible transitional and also hybrid forms were recently reported from Jarmo, a highland Zagros site of sedentary groups dated into the late 8th mill. BC. Possible domesticated pigs appeared considerably later in isolated, but “fully neolithized” village communities in NW-Iran. Interestingly, the appearance of pigs in NW-Iran can be equally associated with growing forestation in the respective region. Moreover, relevant settlements were located to swamp and watered areas. The evidence raises the question, whether swine husbandry has taken place in concordance of changing ecosystems, or was brought by migrating groups inclusive pig flocks beyond other domestic species. It lets us also consider another scenario: animal management as a highly adaptive technology of groups that combined hunting and herding in the rising forests of the Iranian highland.

1029 CHANGING PERCEPTIONS ON TILE, BRICK, AND ARCHITECTURAL TERRACOTTA ? NEW RESULTS AND DIRECTIONS IN RESEARCH

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Hamari, Pirjo (University of Helsinki; Finnish Heritage Agency) - Rheeder, Annalize (German Archaeological Institute) - Wagner, Natalie (German Archaeological Institute)

Session format: Regular session

Made from fired clay, brick, tile and decorated architectural terracottas are among the most abundant material remains from Antiquity. In recent years, there has been a renewed interest in this material, recognised as an underutilised source of information in archaeological research. New results demonstrate that there are now better possibilities than before for using ceramic building materials as evidence and drawing further conclusions. For example, more detailed scientific analyses, a better understanding of the production and use processes, and emerging, more detailed knowledge of forms and types are producing interesting results and new data. New research also reveals gaps in our knowledge and highlights many possible approaches to this material.

This session invites researchers interested in this material to join the discussion and share their latest findings and discuss new research avenues and growing collaboration. We are inviting contributions from the entire Mediterranean region, spanning from the Classical to Medieval period. The session is particularly interested in contributions that focus on, e.g.:

1. New methodologies in tile, brick and ceramic building material research.
2. Individual finds of different kinds, contributing to a better understanding of emerging typologies (local, regional, trans-regional).
3. A closer examination of production methods, individual workshops, or the identification of elements related to serial production.
4. Questions related to production, construction, and maintenance processes.
5. How objects change and are reused, including their secondary life-cycles.
6. Chaîne opératoire and technical variability.
7. Scientific analysis, including elements, petrography, colours, applicability, and new results.
8. Technical characteristics of the material.

9. New methods for documenting and analysing data.

10. Other tile and brick-related topics.

ABSTRACTS

1 CERAMIC BUILDING MATERIALS IN THE BATHHOUSES OF THE SOUTHERN LEVANT

Kowalewska, Arleta (The Zinman Institute of Archaeology, University of Haifa)

This presentation brings together and discusses various types of CBM (ceramic building materials) that occur in construction of hypocausta of Roman-style bathhouses in the Southern Levant. Although bathhouses and bathing suites are among the common types of buildings in the Roman and Byzantine Southern Levant, the CBM used for the hypocausta construction is an understudied and underpublished topic, disregarded in excavation reports and general studies of the regional economy.

First, the typology of the CBM (various bricks, tubuli, rooftiles, and cylinders) is presented, based on the material collected in the Database of Roman to Early Islamic Bathhouses of Iudaea/Syria-Palaestina and Provincia Arabia (<https://ochre.lib.uchicago.edu/BATHS/>). Then the CBM types are compared to their counterparts from other regions of the Roman World, concluding on the typical products as well as regional innovations and preferences. Last, remarks are given on the CBM's provenience, production, and distribution in the Southern Levant, emphasizing on the still open research questions and possible research avenues to answer them.

2 CBM IN ITS CONTEXT - A CASE STUDY FROM GERASA/JERASH (JORDAN)

Ebeling, Philip (University of Münster)

Within my contribution to the session, I want to report about the insights gained by comparing different contexts in which CBM was retrieved from one settlement only. Several areas of excavation researched by the Danish-German Jerash Northwest Quarter Project in Gerasa (Jordan) held various types of CBM, mostly roof tiles. The comparison of these collections makes differences in types, amounts and nature of deposition clear. All these different characteristics demand interpretation. Also, the differences in composition and nature makes for insights concerning the different ancient roof-scapes of the city of Gerasa. Thus, CBM has the potential to provide significant evidence for a much larger network of knowledge. However, comparing the results of in-depth object studies (several typologies, production marks, petrography, etc.) gives valuable insights into how ancient people approached CBM. Considering, that all these results are connected to objects, not just in space, but also in time, we can, with growing knowledge, find more chronological markers within CBM and “make it datable” in the future.

3 CERAMIC BUILDING MATERIALS FROM THE PROMONTORY PALACE AT CAESAREA MARITIMA

Gleason, Kathryn (Cornell University) - Wissinger, John (Crozier Fine Art)

The Promontory Palace at Caesarea, built into the Mediterranean just south of the city's harbor, was constructed by Herod the Great between 22-12 BCE (Burrell 2014) and was occupied continuously for the next four hundred years. (Gleason 1998) At various points it featured a tile roof, as well as a wide array of heated rooms, bath suites, and irrigated gardens employing CBMs. Drawing upon the materials found during the University of Pennsylvania/Hebrew University excavations from 1990 to 1996, the authors created a preliminary typology of all CBMs, observing two distinct roofing systems, each comprising a variety of fabrics and brick stamps, but not interchangeable.

Caesarea Maritima was an entrepôt for trade routes around the Roman world, offering the potential to examine the palace's CBMs within the current discourses on tile shipment and regional production (Mills 2013). This paper raises key questions, e.g., the date and source of tiles for roofing, as Herod the Great's other palaces were flat roofed, as well as how the wide range of tile types fits into recent syntheses across the region and, perhaps, the wider Mediterranean (Mills 2013; Hamari 2017).

4 REMARKS ON BRICK AND TILE PRODUCTION AND CONSUMPTION IN BYZANTINE THESSALONICA

Raptis, Konstantinos (Ephorate of Antiquities of Thessaloniki)

The present paper examines the organization and the development of the brick and tile production in Late Antique and Medieval Thessalonica, from the Early Byzantine period until the first century after the Ottoman occupation (4th – 16th centuries CE).

It discusses the spatial distribution, the organization, and the establishments of the brick and/or tile production workshops that were functioning at the outskirts of the fortified city, and examines the brick and tile formats, the raw materials and the moulds used for their production, as well as various types of embossed brickstamps of the Thessalo-

nian state brick-production workshops, used probably as trademarks in order to ascertain the circulation, control the quantities and certify the quality of each workshop's output.

At the same time it considers the consumption pattern of ceramic building materials in a constantly active in terms of building activity Byzantine urban centre, attempting to propose alternative research directions regarding their, ignored so far, study.

5 ROOF TILES IN CAVES; AN ENIGMA

Koskinas, Aristotelis (Independent researcher)

In Oinoe, Marathon, Greece, there are two adjacent caves, designated Oinoe II and Oinoe IV; the former was discovered and briefly excavated in 1958 by Ioannis Papadimitriou. It was identified as the Cave of Pan, which had been described by Pausanias in his Description of Greece. In 2012 the Ephorate of Palaeoanthropology - Speleology began an excavation project to investigate both caves. In the Cave of Pan (Oinoe II), among finds dating from the Neolithic period to the 6th century CE, over 200 fragments of roof tiles and bricks were identified. A large number of roof tile fragments were also found in Oinoe IV. It is interesting that the caves of Marathon are not the only ones where roof tile fragments were deposited, since roof tiles have been found in other caves in Greece. This presentation will describe the general characteristics of the roof tiles found in Marathon, as well as their distribution in the two caves. It will also discuss the issues and questions raised by the presence of roof tiles in a speleological context.

6 ROOF TILES UNDER THE MEDITERRANEAN. THE MARITIME CIRCULATION OF CERAMIC ROOFING MATERIALS IN THE MID-WESTERN MEDITERRANEAN OF ROMAN PERIOD

Tomizza, Caterina (Department of Humanities, Ca' Foscari University of Venice) - Beltrame, Carlo (Department of Humanities, Ca' Foscari University of Venice)

Albeit being among the most important market segments in the Roman world, many questions still remain about the mechanisms that regulated the circulation of the ceramic roofing materials. It seems clear that, during the Roman period, most of these materials circulated by sea and probably through different forms of navigation, however, only a few of the cargoes so far detected in the Mediterranean basin have been studied with a complete approach. Here is proposed an analysis of the shipwrecks that includes an outlining of the stowing techniques and an attempt of reconstruction of the forms of navigation employed for the distribution of this sort of commodity. To reconstruct the stowage methods used for the ceramic roofing materials, there has been carried out an analysis on the sites' documentation to find out if there were some blueprints in the disposition of the roof tiles and cover tiles on board. The stowing patterns observed could be resumed in a general scheme whereby the roof tiles are arranged in parallel rows, positioned in the middle of the hull, with the cover tiles disposed in side stacks and inserted vertically in the gaps. The systematic study of the shipwrecks led to the hypothesis that the diffusion of the ceramic roofing materials took place on various scales and through different sailing modes, in contrast with the outdated theories that considered roof tiles and cover tiles as resalable ballast. It would be advisable a systematic study of this type of materials that starts from morphological and epigraphic analysis and necessarily passes through archaeometrical studies, considering both shipwrecks, production facilities, storage and redistribution sites.

7 A DIGITAL METHODOLOGY FOR THE MENSIOCHRONOLOGICAL ANALYSIS OF THE ROMAN BRICK-FACED MASONRY

Fornaciari, Lorenzo (École française de Rome)

This contribution aims to illustrate the development of a methodology for the mensiochronological analysis of the Roman brick-faced masonry that is developed through rigorous surveying, measurement and statistical data analysis in a GIS environment.

Mensiochronological analysis, even today, mostly uses traditional tools with enormous time and fieldwork costs and is consequently often conducted on restricted contexts only on specific occasions or for special needs.

The lack of quick and common procedures capable of increasing the possibilities of application and returning coherent data that can be truly compared, for a long time constrained these analyses to only attempting to date the individual structures, neglecting the broader meaning of mensiochronology in which data must be included in a global horizon dedicated to the brick-faced masonry that intersects with historical-geographical, socio-economic and technical aspects.

Digital survey techniques, the AI's image recognition and the spatial and statistical analysis GIS functions now offer the possibility of overcoming these limitations. It is a matter of developing a standardised and rigorous procedure that is not only accessible and quick, but that, once the rules have been established, allows data produced following a common procedure to be compared and statistically analysed even if they concern different structures and buildings.

This approach, of which some results will be presented for the Baths of Elagabalus and for the northern substructures of Vigna Barberini on the Palatine Hill, aims to deepen the study of one of the most common materials of Roman building by highlighting the use and reuse of bricks, the technical skills of the workers in preparing and setting up them, the supply of materials and the dynamics of the construction process.

Finally, it will be an opportunity to share with the scientific community the GIS analysis model available as a plug-in for the QGIS platform.

8 BETWEEN LAB AND FIELD: INNOVATIVE METHODOLOGIES FOR ANALYZING ANCIENT ARCHITECTURAL TERRACOTTAS

Wagner, Natalie (German Archaeological Institute, Rome)

The study of ancient Architectural Terracottas stands at the threshold of new scientific insights, driven by innovative methods ranging from archaeometric analyses to 3D reconstructions. This presentation sheds light on these methodological advancements through case studies from Capua and Rome, spanning from the 6th century BCE to the 1st century CE. The focus is not on the results of the archaeometric analyses themselves, but on the applied methods and their potential for archaeological research.

Provenance analyses, providing insights into the origin of the clays used, and pigment analyses, examining the coloration of the architectural terracottas, offer new perspectives on assessing ancient production and trade networks as well as aesthetic conventions. These are complemented by the use of 3D reconstruction techniques, which enable the virtual restoration of the original arrangement and appearance of the roof tiles to explore architectural contexts and construction details.

These methodological approaches revolutionize our understanding of material culture and the technological capabilities of ancient societies. They allow for a detailed and nuanced examination of roof tiles that goes beyond traditional typological classifications, providing insights into the complex production, trade, and application practices of antiquity.

9 ROOF-TILES IN GREEK SICILY FROM THEIR APPEARANCE TO THE ROMAN CONQUEST

Giuliano, Dario (Università degli Studi di Palermo; Université Bordeaux-Montaigne)

This contribution stems from the study conducted within the doctoral project focusing on the study of roof tiles in Sicily from their appearance to the Roman conquest. A class of materials, the one under examination, notoriously undervalued. The study focused on the colonies of Himera and Agrigento, but the results obtained were also found in other contexts on the island. The choice fell on these cities because Himera provides the oldest evidence of a terracotta roof from the island, while Agrigento, thanks to its uninterrupted habitation from its foundation to the present day, would have allowed highlighting any changes in roofing systems or roof-tiles used in them. For this purpose, different contexts were analyzed: residential, sacred, necropolises, in order to understand if there were types used in specific contexts. All fragments were examined and studied, allowing for a complete reconstruction of the different phases of the production chain.

The significant quantity of materials analyzed has allowed a clear definition of the morphological characteristics of the roof-tiles belonging to different systems: Corinthian, hybrid, and Laconian, proposing a better definition of them; furthermore, a chrono-typological seriation of the roof-tiles for the period under examination is proposed.

10 SERIAL PRODUCTION, WORKSHOPS AND THE CREATION OF TYPOLOGIES FOR UNDECORATED ROOF TILES

Rheeder, Annalize (German Archaeological Institute)

The high level of standardization found in undecorated roof tiles is an obstacle to the creation of typologies based on size and profile alone. Recent studies indicate that assemblages can be further differentiated by adding production techniques to the analysis. Ethnographic documentation of traditional tile works show tiles produced in series where the same material, tools and steps are repeated with minimal variation. The specific combination of material and techniques depend on the craftsmen or workshops. Even within regions with a very homogenous production tradition, differences in production techniques can still be observed between workshops. Observations made on tiles from Pergamon, Pompeii, Olympia and the Kerameikos as part of work in the DAI's Digital Roofs project correspond to the ethnographic results. Based on traces left on the objects it is possible to reconstruct not only the production sequence, but also specific techniques used within each production phase. The addition of production to the investigation of objects aid not only in the classification of objects by type, but also have the potential of identifying individual production series within each type. A diachronic view of assemblages furthermore aid in the investigation of regional or period specific tile production through the identification of production traditions.

11 MAPPING THE DIFFERENCES, UNDERSTANDING EVOLUTION: THE GROUNDS FOR SUGGESTING REGIONAL TYPOLOGIES FOR ROMAN-PERIOD ROOF TILES IN THE EAST

Hamari, Pirjo (University of Helsinki)

In 2019, I finalised my PhD dissertation on the Roman-period roof tiles in the Eastern Mediterranean (Hamari 2019). One of its aims was to get an overview of the types of ceramic roof tiles in use in the Roman period in the eastern part of the Mediterranean, as they clearly differed from those in the western provinces. My own primary material comes from Greece and Jordan, providing a starting point for a wide geographical overview.

In my presentation, I will present the source material used in summarised format, consisting of my primary material as well as a relatively extensive search for other published examples, with the aim of continuing discussion on the typology proposed and potentially enlarging the source material providing the foundation for such a typology. Finally, a question is posed on the possibility to build an accessible reference database in support of a developing typology of the eastern roof tiles.

1030 SURVEYING IN ARCHAEOLOGY IN THE DIGITAL ERA: RETHINKING OLD PROCEDURES AND IMAGINING NEW STANDARDS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Cavalazzi, Marco (Università di Bologna; University of Michigan) - Johnson, Tyler (Kelsey Museum of Archaeology - University of Michigan) - Putzolu, Cristiano (Università di Bologna)

Session format: Regular session

Field data-collection has greatly evolved due to ever-advancing Information and Communication Technology (ICT), which has found an increasing place in archaeology. Particularly, archaeologists are faced with the problem to document the three dimensions of archaeological contexts (width, length, and depth), and their evolution in time (the so-called 4D), as well as to document the continuum of archaeological landscape, considering the single archaeological feature (e.g. a site or a stratigraphic unit) as part of a more complex geographical palimpsest.

In this session we would like to present and discuss the impact of digital technologies on the every-day practices of the topographical survey, within the different sectors of in-field archaeology, as well as to highlight the limits and the implicit and explicit theoretical and methodological consequences of these practices.

Recent digital survey workflow are mostly focused on three main approaches: a Processual style analysis (collection and analysis of large datasets), a Phenomenological style analysis (often focused on using reconstructions to study the perception and feeling of ancient environments), and the development of applications for Heritage management and valorisation (such as tourism/educational application or conservation). However, hardly anyone is focused on methodologies for field surveying, even if the characteristics of the digital data themselves - in particular their level of resolution and their informative value/limits - are, almost spontaneously, generating a new momentum in the debate about epistemological processes in archaeology.

We seek papers presenting case-studies and considering aspects of self-criticism and self-awareness of topographical data-collection and management workflows, as well as related to the analysis of the level-of-detail and level-of-information-need of the archaeological data acquired with digital technologies.

ABSTRACTS

1 SURVEY IN 2024, BETWEEN LEGACIES AND FUTURE

Pintucci, Alessandro (Confederazione Italiana Archeologi)

Over the last 20 years, 3D survey techniques have made great strides and have rapidly become available to a growing number of professionals and public and private archaeological organisations. The traditional techniques of archaeological survey and structural analysis of ancient complexes have been supported by innovative and promising representation techniques, which, although not without contradictions, have quickly ended up replacing the old systems, opening up new research perspectives.

While this evolution was taking place, the world of archaeology, from the academy to the Ministry of Culture, up to the professionals engaged in the so-called commercial archaeology, despite largely mastering the new tools, did not have the ability, or the time, to rethink the discipline, taking into account the new possibilities, what was gained and what there was a risk of losing; in this intervention we will try to address some issues raised by the use of these systems: the risks connected to the progressive detachment from archaeological materiality, the rapid technological changes and the obsolescence of the tools, the lack of interoperability and the risk of obsolescence of the formats, the need to

adapt the forms of scientific publications to new media, overcoming the graphic standards born in a purely analogue era of representation.

2 THINKING OUTSIDE THE SQUARE: A CASE STUDY ON THE VALIDITY OF THE ARCHAEOLOGICAL SURVEY

Valsecchi Gillmeister, Margherita (Freie Universität Berlin)

Surface archaeological data are often the most accessible and readily available source of information about past cultural landscapes. In particular, survey is a well-established method for research in Northern Anatolian archaeology, where extensive regional surveys are more common than excavation. Considering this situation, the question about the reliability of modern historiography and archaeological interpretations based on the surface results for this region or other areas with a similar state of research comes to mind.

A possible approach to assess the reliability of surface collections is their cross-checking against the subsurface data. The multiperiod site of Oymaağaç Höyük (Samsun, Türkiye), with its long-term multidisciplinary research, is suitable as a case study for this kind of analysis. The large dataset collected at the site in the last two decades is available in the OpenSource MySQL server-based excavation database, offering a broad range for comparison against geophysical prospections, excavation results and artefacts data.

Starting from the cross-check of the surface pottery assemblages at Oymaağaç Höyük against the available subsurface evidence, this paper aims to discuss the validity of archaeological survey while discussing the methodological challenges arising when comparing records documented in different periods by different specialists, the importance of a coherent approach to data collection through time and space, and the possibilities and shortcomings of processing data collected by a multidisciplinary and international team.

3 AN APPROACH TO PERIOD-BASED ARCHAEOLOGICAL SURVEYS: THE LATE IRON AGE IN OMAN AS A CASE STUDY

Mauro, Fausto (Heidelberg Center for Cultural Heritage)

In the Arabian Peninsula, communities have consistently demonstrated remarkable resilience and adaptability when facing environmental constraints and societal transformations. This project aims to explore the narrative of such resilience among ancient communities in south-eastern Arabia, with a specific focus on the underexplored Jebel Madar area (Sultanate of Oman) during the Late Iron Age (LIA, ca. 300 BCE – 300 CE). Therefore, this research intends to reveal the density of LIA sites around the Jebel Madar and the relations with the surrounding areas.

Starting from geospatial analysis and robust data gathered across the country, Archaeological Predictive Modelling (APM) and remote sensing are going to guide the field survey in the area of interest. However, it is crucial to acknowledge the inherent limitations of these methods, especially when applied to specific centuries. For instance, the nature of LIA architecture makes it challenging to effectively detect sites through remote sensing. Simultaneously, the APM, while a valuable tool, has often remained untested on the ground. Thus, the field survey is intended not only to validate the efficacy of these methods in Arabian contexts but also to highlight further limits and seek to overcome them, particularly when targeting single chronological periods.

The paper presents the results and reflections of the first survey.

4 REFRAMING DIGITAL FIELD SURVEY STRATEGIES: SELF-CRITICAL EVALUATION OF THE DATA COLLECTION WORKFLOW IN THE WEMALP PROJECT (GREECE)

Bottoni, Margherita (Università degli Studi Roma Tre) - Rossi, Matteo (Università degli Studi di Roma "Tor Vergata") - Fasson, Federico (Università degli Studi di Bari Aldo Moro) - Scoz, Jacopo (Sapienza Università di Roma)

The Western Megaris Archaeological Landscape Project (WeMALP) is led by Roma Tre University, the Italian Archaeological School at Athens and the Archaeological Service of Western Attica. The project started in 2019 and aims to investigate the diachronic relations between the city and the countryside, as well as the rural use of the area in the *longue durée*. The *équipe* involves international researchers, undergraduate and graduate students.

In this paper, we aim to reflect on the workflow which allows the project to collect high-resolution and multi-scaled data during the field activity. Our workflow is not static, but it needs to be constantly self-rethought and reframed, taking into account our logistical, economic and training issues, in order to obtain the highest possible quality of the data. The reflection involves the whole *équipe* through a call for multivocality and self-awareness.

This theoretical approach is applied in the whole range of our field activities, that include artifact surface survey, enhanced by mobile GIS applications, architectural features survey with DGNSS devices and UAVs 3D photogrammetry, and sporadic shovel tests. The daily routine of data acquisition and processing allows us to reframe our use of these technologies on the field, depending on the ease of their application and the quality of the data obtained. Widening

the frame, the time gap between the different campaigns allows us to hypothesize major changes to the management of our workflow, in terms of the methodologies and the target of our research.

By describing our self-aware approach to the application of digital technologies and the evaluation of the collected data, this paper aims to develop self-criticism on the WeMalp's workflow, fostering a collective discussion during the Session.

5 USING KOBOTOOLBOX FOR FIELD DOCUMENTATION OF AFRICA'S HERITAGE SITES: EXPERIENCES ON THE DEPLOYMENT OF A MOBILE FIELD RECORDING APPLICATION

van der Merwe, Renier (Origins Centre, University of the Witwatersrand) - Kiala, Serge (Origins Centre, University of the Witwatersrand) - Merlo, Stefania (McDonald Institute for Archaeological Research, University of Cambridge) - Ochungo, Pamela (British Institute in Eastern Africa) - Lander, Faye (Origins Centre, University of the Witwatersrand)

Today, digital ground surveys are characterised by the deployment of a vast array of advanced ICT-based instruments that capture quantitative data at different scales, using heterogeneous methods and storing them in different formats. Notably, the capturing of qualitative information, including that on methodological decisions that characterise the design of the survey itself, has often continued to be carried out in paper format (or digital replications of a notebook). Field-based applications such as Open Data Kit (ODK) and KoboToolbox (koBo), which capture field data using mobile data collection methods, offer an opportunity to optimise the workflow of data collection. These applications are highly popular because of cost-effectiveness, efficiency, and user-friendliness. They can also operate in remote areas with limited or no internet connectivity, ideal for many types of fieldwork missions.

In the Mapping Africa's Endangered Archaeological Sites and Monuments project, KoboToolbox is used for the ground verification and survey of heritage sites identified through legacy records and remote sensing. Several iterations of a customized digital field recording form have been developed and deployed since the project began in four African countries (Kenya, Tanzania, Zimbabwe, and Senegal). The digital form is partly structured on the original paper-based site recording forms used by in-country national heritage authorities and museums. At the same time it serves as a locus for the aggregation of both quantitative and qualitative data on the sites and the capturing of information on survey methods used for the recording. Although chosen for its user-friendliness and efficiency, several challenges have emerged with its application, not least the integration of a new and unfamiliar digital technology with the more familiar traditional field recording methods. Drawing on case studies, we reflect on the challenges and opportunities of mobile field data recording methods in the context of a multi-stakeholder collaborative project.

6 SYSTEMATIC SURVEYS AND CONTEXTUAL ANALYSIS OF EVIDENCE IN THE SIBARITIDE AREA (NORTHERN CALABRIA)

Valentini, Giuseppe (Sapienza University of Rome, Rome, Italy) - Vanzetti, Alessandro (Sapienza University of Rome, Rome, Italy)

The Sibaritide, located in the northwestern part of Calabria, is renowned for its rich archaeological density, which attests to the existence of ancient civilizations and significant settlements, thus emphasizing the historical and cultural significance of the region in antiquity, along with the preciousness of its archaeological heritage.

This study proposes a detailed analysis of settlement dynamics in the Sibaritide through field surveys and contextual analysis of archaeological evidence, supported by geographic information systems and digital tools.

While in the 1980s field research was predominantly manual, today advanced digital technologies enhance efficiency. Traditional sampling strategies remain valid and integrate well with new technologies, proving advantageous even in contexts with limited digital resources. In particular, the use of GIS for digital procedures proves invaluable in geomorphological evaluation, enabling a more thorough and comprehensive analysis of the territory.

The focus was on the area surrounding Cerchiara di Calabria (CS), using a systematic-random sampling methodology of 10%. The main objective was to identify and map archaeological evidence, to compare settlement variations over time and consider the surrounding environment.

For data analysis, the QGIS software was used, while LiDAR data were employed to examine natural morphologies and traces of terracing in the identified areas. Overall, the study identified and mapped 43 areas of archaeological dispersion, spanning from the protohistoric period to the post-classical era. These results are of considerable importance as they provide valuable insights into settlement dynamics and human presence in the studied region.

In conclusion, the study adopts a combination of research methodologies and analytical tools to obtain meaningful information about the population and occupation of the territory in a part of the Sibaritide, thus contributing to the understanding of the history and archaeology of the region.

7 AN INTERDISCIPLINARY AND NON-INVASIVE APPROACH TO INVESTIGATE THE ARCHAEOLOGICAL LANDSCAPE OF BRIATICO (CALABRIA, ITALY) IN THE LONGUE DURÉE

Coleschi, Alessandra (Università di Siena) - Dalle Vedove, Letizia (Università di Siena)

Since 2021, the University of Siena carried out research campaigns to study the territory of Briatico (Calabria, Italy) with the aim of providing a diachronic reconstruction of the historical landscape, particularly the agricultural one. The project focused on the analysis of scattered settlements, especially to identify the ancient dwellings and farmhouses, which are linked to the exploitation of the rural territory. The research was developed through a multidisciplinary approach, considering both remotely and on-site surveys. The interpolation of data and the support of GIS based technologies, revealed a continuity of land-use attested from the Middle Ages onwards. The GIS platform was useful to create geoprocesses and to study the sites and their correlation with the surrounding territory, encompassing morphological, agricultural and settlement aspects. Other tools, including centimetric GPS, the Qfield android app and a multi-rotor drone, have been used to carry out an accurate documentation and a photogrammetric survey of the ancient center of San Leo Vecchio, which was abandoned after the earthquake of 1783. Accordingly, the site has a great archaeological potential and represents the ideal context to study settlement dynamics and the relationship with the surrounding landscape.

The three-dimensional model has facilitated a more effective study of the site in its current state, thereby preserving its memory and promoting local policies conservation efforts to avoid its total destruction, prioritizing preservation and enhancement is highlighted.

The research conducted only through the digital survey has returned a partial view of the archaeological content and the limits have been emerged already in the first phase of exploration and knowledge of the territory, for which it became necessary a field verification for each site identified, for a greater and closer analysis of the data already acquired, including systematic surveys and collection of oral sources.

8 THE UNINETTUNO ARCHAEOLOGICAL PROJECT AT ROSSOMANNO (SICILY): METHODS, APPROACHES AND TOOLS FOR SURVEY AND DATA COLLECTION

Brienza, Emanuele (Università Telematica Internazionale Uninettuno) - Girella, Luca (Università Telematica Internazionale Uninettuno) - Draìà, Eleonora (Università Telematica Internazionale Uninettuno) - Anzalone, Marco (Università Telematica Internazionale Uninettuno)

TRossomanno is an archaeological site in inner Sicily, occupied since the Bronze Age and almost uninterruptedly to the Medieval time. Emergency excavations have been carried out in the past, although poorly edited. A new project between the Soprintendenza ai Beni Culturali ed Ambientali di Enna and the Uninettuno University started in 2022 to investigate the urban and archaeological vicissitudes of the site, identifying the characters of coexistence, integration, and development of ancient different "cultural" communities, framed in the historical events of the largest territory of Sicily. The survey has been carried out following non-systematic, systematic, and intensive archaeological survey. Specific formats for archaeological written data recording have been used: file-cards for Topographic-Unit (UT), for Structural Context Unit (USM) but also for the Squares (SQ) into which the systematically surveyed areas have been divided. The graphic and topographic documentation has been implemented by using new smart GNSS centimetric positioning tools (Trimble DA2 Catalyst) and digital SFM photogrammetry, close range and aerial (by UAV-UAS): horizontal and vertical orthophoto-maps have been elaborated for archaeological evidence, together with DSMs and DEMs and vectorial drawings have been done using them as a basis. All data are managed by GIS software inside a wider geodatabase dedicated to all the archaeological sites of the Erei.

In our intention scientific results should become the source for an evaluation of site enhancement and relative impact on the current economic and social context: our activity is focused on the impact on the territory, proposing a development model based on propitious relationship between inhabitants, landscape, and cultural assets. From this perspective diffusion and participation are the main target: workshops, public meetings and open days on the site have been organized to refer to the ongoing activity and to discuss with all the stakeholders about future development perspectives.

9 DOCUMENTING THE ARCHAEOLOGICAL RECORD: REFLECTIONS ON THE RELATIONSHIP BETWEEN DIGITAL ARCHAEOLOGY AND THE CONCEPT OF STRATIGRAPHIC UNIT

Putzolu, Cristiano (Dipartimento di Storia Culture Civiltà, Università di Bologna) - Cavalazzi, Marco (Dipartimento di Storia Culture Civiltà, Università di Bologna; Department of Classical Studies, University of Michigan)

The digital revolution in archaeology has profoundly transformed data collection procedures and the nature of archaeological information itself. On one hand, the positive consequences of this revolution are evident: field workflows are quicker, surveys are more accurate, data are more easily reusable and shareable, and new digital approaches frequently revitalise the theoretical debate in the discipline.

However, on the other hand, digital workflows have also had negative impacts on research. For example, they are often applied uncritically, they create a digital barrier between the archaeologist and the archaeological evidence, and lead to the production of vast archives of digital outputs that are difficult to manage.

However, far from being an over-exploitation of new technologies, digital archaeology can update the paradigms of archaeological research, as has already occurred since the introduction of radiocarbon dating.

Building upon these considerations, this paper aims to examine how archaeologists are currently dealing with the challenge of defining archaeological information; specifically, it will examine how archaeologists express their data through digital outputs, whether written or illustrated, and how they archive fieldwork information. The focus of the discussion will be on a key concept: the stratigraphic unit, the smallest unit of archaeological deposit documentation. We will analyse how this feature is defined and documented in different research traditions, exploring how digital advancements are reshaping this type of data and our understanding of them.

To accomplish these objectives, we will delve into various case studies, such as the excavations of Gabii in Rome, Cervia in Ravenna, and Colombare di Negrar near Verona, among others, discussing the ongoing research conducted by the authors.

We believe a deeper exploration of the implications of digital approaches in archaeology can catalyse advancements in the theoretical debates within archaeology, facilitating novel approaches to the relationship between epistemology and ontology in this research domain.

10 STRATEGIES AND METHODS IN DOCUMENTING AND NARRATING TANGIBLE CULTURAL HERITAGE. THE CASE OF S. LORENZO IN MIRANDA (ROME)

De Stefano, Francesco (Sapienza Università di Roma) - Cecconi, Niccolò (Sapienza Università di Roma) - Griffo, Marika (Sapienza Università di Roma) - Porfiri, Francesca (Sapienza Università di Roma) - Ippoliti, Mattia (Sapienza Università di Roma) - Pavia, Davide (Sapienza Università di Roma) - Moricca, Claudia (Sapienza Università di Roma) - Perrone, Francesca (Sapienza Università di Roma)

Many cultural heritage assets and contexts are still not adequately documented and known. This increases the risk that this potential wealth of knowledge will be lost forever due to the threats of urban sprawl and the natural and anthropogenic erosion to which it is exposed. Furthermore, it prevents adequate cultural communication. These heritage contexts must therefore be transformed into documents and systems of knowledge through epistemological and hermeneutic procedures, so that they can be turned into images and narratives that illustrate the flow of large and small stories. These premises are the basis of the PNRR Project CHANGES - Spoke 8. The main objectives of the Project are the integration of technologies and sciences for Tangible Cultural Heritage (TCH); the creation and development of digital infrastructures for TCH inventories/catalogues capable of supporting different knowledge pathways and maximising accessibility. Within this framework, a relevant topic concerns strategies and methods for documenting and analyzing built spaces and reconstructing parts of ancient landscapes. One of the main challenges of the Project is to verify how different data sources can coexist in the same 3D digital environment. Due to this, Heritage Building Information Modelling (HBIM) provides a wide range of tools in terms of data representation and information extraction. The possibility of relating data sources to visible structure and reconstruction hypothesis will be illustrated through a specific case study: the church of S. Lorenzo in Miranda along the Via Sacra route, near the Roman Forum. Originating as a temple dedicated to the emperors Antoninus and Faustina, and later becoming a church, this context is particularly significant for the overlapping and diachronic relationship between open spaces and built contexts within a place of special historical and architectural significance.

11 SURVEY AND ELABORATION OF DIGITAL DATA FOR A STRATIGRAPHIC ANALYSIS OF PLURISTRATIFIED CONTEXTS: THE S.C. DOMUS DEGLI AMERICANI (PALATINE, ROME)

Bossi, Sara (Sapienza University) - Squartini, Nicolò (Sapienza University) - Mele, Samira (Sapienza University)

With this contribution, we would propose and discuss the digital technologies methods, strategies and procedures about acquiring and elaborating data, focusing on the case-study of the s.c. Domus degli Americani (Palatine, Rome).

The monument is a late-antique domus along the eastern slope of the Palatine Hill. Today, it lies within the limits of the Parco Archeologico del Colosseo in the area investigated by Sapienza University (Prof. M.T. D'Alessio). It dates from the third to the fourth century AD, constructed in place of earlier structures, varying in functions and erected since the fourth century BC. The building was excavated between 1989 and 1993 using a stratigraphic method by an international team led by Hostetter and Howe (AAR). Latest documentation has been produced by Parco Archeologico del Colosseo.

The context is of primary topographical, historical, and architectural significance, requiring a thorough analysis of the published, sometimes incomplete, documentation and visible stratigraphy. It is of the utmost importance to gain a

deeper understanding of a monument which to-date has been only partially read from a diachronic perspective and in its proper context.

Field and laboratory analyses are still ongoing. The aim is manifold: acquiring new data, verifying, and integrating information already published by AAR and in historical cartography. Our work is divided into an initial survey phase, in plan and elevation, of each evidence, utilizing GNSS antennas (Leica GS15), total stations (Leica TS15), laser scanners (Leica RTC360), photogrammetry. The new graphic documentation makes up the base for an autoptic stratigraphic analysis of the visible evidence. This approach allows diachronic interpretation of the monument and its narrative over time.

All data is acquired and processed digitally. Our goal is to apply a methodology that is as precise and effective as possible, crucial for the required level of detail, involving interoperability between tools and operators.

12 REASSESSING THE LEGACY SURVEY DATA FROM KARANIS (EGYPT) IN THREE DIMENSIONS

Johnson, Tyler (University of Michigan)

The site of Karanis, a Greco-Roman farming village in the Fayum (Egypt), was extensively excavated by the University of Michigan between 1924 and 1935. Although a far cry from modern standards, the Michigan excavators utilized advanced survey techniques for their time. Documenting the evolution of the site through a system of "levels" running from the early Imperial Period to Late Antiquity, the team left behind a dense archival record now housed at the Kelsey Museum of Archaeology (Ann Arbor, Michigan), including detailed section drawings, plans, and dozens of notebooks recording the survey readings used to produce these graphic representations. The majority of these records have yet to be systematically analyzed and published.

This paper presents the preliminary results of a project aimed at utilizing the Karanis survey records to confront ongoing uncertainties about the site's overall phasing. To address this, a methodology was devised for developing schematic 3D representations of buildings at Karanis on the basis of the legacy survey records. Then, an interface developed using the game engine Unity is allowing these models to serve as a framework for a broader contextual reappraisal of the graphic, photographic, and written documentation for the site. Ultimately, this approach supports the division of Karanis contexts into "stratigraphic containers" (groups of deposits), enabling a quasi-stratigraphic reassessment at the most granular level of detail possible given the nature of the original recording techniques. This work raises essential epistemological issues about the relationship between the level of detail in surveying records and the possibilities for subsequent inquiry. While Karanis is thus a case study in addressing legacy data using modern methods, it is also a useful thought experiment for considering the limitations and gaps imposed by current survey methods in constructing the archaeological record.

13 THE ROLE OF DIGITAL TECHNOLOGY IN THE DOCUMENTATION OF EGYPTIAN ROCK ART. EXPERIENCES FROM YALE EGYPTOLOGY EXPEDITIONS

Urcia, Alberto (Yale University)

The use of digital technologies in archaeology has reached, over the past few years, a predominant role within the discipline. Recording techniques such Structure from Motion and laser scanning, largely enhanced the amount of surveying data that archaeologists must manage to produce results and achieve their research goals. Software and devices for 3D imaging and measurements have been significantly improved, increasing the chances to gather good, or at least acceptable data, also by non-experts in technology. This is certainly positive but is it bringing only benefits? The data is indeed increased but how much do we know about its quality and how much can we rely on it? Digitizing material culture produces virtual copies of real objects on which we can work at any time. This may help their preservation, speed up field work procedures and reduce the distortion of our subjectivity while recording. But are all these just advantages? Do we know how to properly handle the relationship and interaction between virtual and reality? Is it clear how much this new technological influence is contributing to produce new archaeological knowledge?

Egypt has many rock art and inscriptions sites, mostly carved and spread all over the country, differentiating in typology, chronology, size, importance and preservation status (often precarious). Working with all the above questions in mind since over a decade, Yale Egyptology, together with other affiliated projects, was able to build a reliable Digital Epigraphic methodology based on the interaction between 3D imaging, topography, archaeology and philology. The recording workflow was designed to fulfill two main requirements: keeping the petroglyphs connected to their geo-environment and producing data on time to be collated in front of the original artifacts. These conditions imposed to adopt a multi-resolution and multi-scale approach, functional enough to generate faithful graphic materials and reliable research tools.

UNVEILING PRECISION: THE CASE FOR SMALL ARCHAEOLOGICAL FINDS IN 3D PHOTOGRAMMETRY

Lauro, Vittorio (Università di Torino) - Lombardo, Vincenzo (Università di Torino)

Photogrammetry has emerged as a pivotal tool in archaeological research, yet its application encounters unique challenges when dealing with small-scale objects.

Shadows, occlusions, variable lighting conditions, and the scarcity of distinctive feature points are hard obstacles. Moreover, objects with intricate geometries, challenging textures, and materials that feature complex optical properties increase these difficulties.

Researchers have innovated tailored solutions for photogrammetric scanning challenges on small objects. It can be deduced that to share these experiences and develop some common knowledge about the task of scanning small objects, it is paramount to share and compare the experiences. This can be done through some acknowledged metadata-tion. In the literature, there have been some attempts at interoperability, that address the critical need for traceability and comprehensiveness of metadata recording in photogrammetric processes. To foster the exchange of experiences and cultivate collective knowledge on scanning small objects, sharing and comparing experiences through established metadata protocols is imperative. Several endeavors in the literature aim to enhance interoperability, addressing the crucial need for traceability and comprehensive metadata recording in photogrammetric processes.

Our research focuses on standardizing metadata introduction for acquisition methods, considering various factors such as object shape, characteristics of the acquisition set, material properties, and adjustments made in response to light properties. It also accounts for the number of photographs taken, reconstructive algorithms based on prior acquisition methodology choices, and the scanning process across acquisition phases: Acquisition, Processing, Modeling, Export, and Indexing. Ensuring coherence between the structure of RAW data archives and collected metadata is crucial. This standardization effort aligns with CIDOC-CRM, achieved by integrating processes with standard classes and properties, facilitating interoperability and data consistency. We are currently testing the protocol to produce a preliminary evaluation of the method used for the analysis of glass beads from the archaeological site Tobitsuka Kofun in Okayama, Japan.

1033 CHOOSING THE RIGHT CUP FOR THE JOB: FUNCTIONAL AND NON-FUNCTIONAL CONSUMPTION HABITS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Meens, Anna (University of Amsterdam) - Crudo, Maurizio (Independent Researcher) - Stissi, Vladimir (University of Amsterdam) - Witcher, Robert (Durham University)

Session format: Regular session

Think about it: your kitchen cupboards are likely full of vessels of different shapes, sizes, and materials. What are the functional, cultural, and technological reasons for this? Why do we drink wine from one type of glass and water from another? Why are tea and coffee cups different? Why do we prefer ceramic and glass to metal and plastic? How does a soup bowl really differ from a breakfast bowl? Why do we buy another mug with a funny slogan that we'll never use? And do we sometimes use the 'wrong' vessel when no-one's watching?

Parts of the ancient Mediterranean world also demonstrate large and varied vessel repertoires. In some sixth/fifth-century BCE Athenian contexts we find a vast range of vessels related just to wine drinking; in other contemporaneous contexts, however, a few basic types of vessel were sufficient. Archaeologists have traditionally considered the variety of material cultural forms from a practical perspective (e.g. the suitability of shape and material for specific tasks), as well as cost, aesthetics, status and durability. More recently, concepts such as tradition and innovation, the agency of craftspeople and consumers, fashion, and identity formation have also been considered. Whilst there has been research on standardization, however, the proliferation of vessel forms has received less attention. Why are some periods, places, and social groups characterized by a desire for many vessel types, while others have fewer and perhaps more traditional forms?

We invite contributions that reflect on both the uses and meanings of vessels from archaeological contexts, looking beyond the practical and specific explanations, and focusing on consumers' choices and their cultural contexts. Our aim is to compare case studies from different periods and regions, and to explore future directions in research on some of the most common objects of the ancient – and modern – material record.

ABSTRACTS

1 CUPS, SKYPHOI, KANTHAROI, KYLIKES, KOTYLAI, POTIRIA AND THE REST: THE DIVERSITY OF GREEK DRINKING VESSELS (6TH-4TH CENTURY BCE)

Stissi, Vladimir (University of Amsterdam)

As is well known, the diversity of drinking vessels in 6th-4th century BCE Greece is staggering. Even if exact definitions may be problematic, at least a dozen clearly recognizable types can be distinguished, often coming in many variants and in various fabrics and finishes, creating very different looks. Some of the types remained fairly uniform during long periods and over large areas, but others were quite short-lived, or remained confined to limited regions, or particular functional contexts. Yet, while some vessel types may have had more diverse uses, and others very specific roles, the general functional association of (almost) all the types seems to have been wine drinking.

However, even though wine drinking had a very prominent place in Greek society, and may explain the large numbers of drinking vessels (which often form more than half of assemblages) this does not explain their diversity. Perhaps we have to look for more symbolic or contextual explanations. On the other hand, the inconsistent ancient Greek use of terminology using the same word for different types of vessels, but also labelling single types with different names, may indicate indifference and interchangeability. Where can we find solutions?

Scholars have tried to explain diversity in Greek pottery assemblages in various ways, looking both at function and at meaning, but I think a fresh look can be useful, and hope to be able to offer some new more systematic and general reflections, by combining case studies and more overall views. I also want to explore to what extent modern typology and classification may or may not overlap with ancient perceptions, to see whether perhaps some of the issues we look at reflect present rather than past concerns. Finally, I hope to find some inspiration through links with other papers in the session.

2 CULT, CRAFT OR CULTURAL? ON SHAPE VARIETY IN AN ARCHAIC-CLASSICAL SANCTUARY AT PHENEOS, ARCADIA

Klöckl-Zoric, Regina (University of Graz) - Testolini, Veronica (University of Graz)

Living in Pheneos meant being remote from the urban centres of ancient Greece, but not isolated. Surveys have proven Pheneos' position along a road network through the mountains, and external relationships are apparent in the range of finds excavated on the settlement hill of Pheneos. In addition to many locally produced items, there are ceramic vessels and other objects imported from various places in the Peloponnese, Attica and the wider Mediterranean.

In this context, the gift assemblage from a sanctuary on the hill dating from the sixth and fifth centuries reflects consumers' choices. Many visitors decided to bring pottery, and particularly favoured Athenian style drinking vessels. Similar choices were made in other parts of the Greek world in this period and the demand for black-gloss tableware stands out, not only in cultic contexts. Drinking from a black-slipped cup was fashionable, as demonstrated by the incredible diffusion of this technological innovation. Combining stylistic studies and archaeological science, we examine the reasons for this. Why was the Athenian-style black slip so popular among craftspeople and consumers at Pheneos? Was it just practical or is this a case of cultural assimilation?

Other visitors to the sanctuary decided to bring Corinthian pyxides, another large group of offerings. While wine consumption is traditionally associated with the male sphere, the pyxis is regarded a typically female item. We are interested in this apparent contrast, too: is it due to a standardisation of activities in the sanctuary or does it express the identity of the donors?

Our case study investigates aspects of production technology and shape variety to reflect on the agency of craftspeople and consumers, the cultural context and concepts of gender division, and demonstrates how interdisciplinary research can address these questions efficiently.

3 SAME SHAPE DIFFERENT CLASSES. PUBLIC AND PRIVATE CONSUMPTION IN A COMMON REPERTOIRE

Crudo, Maurizio (independent researcher)

In today's globalized society, the same tablewares can be found around the world making it difficult to identify the distinct cultural and social characteristics that were, until the last century, so evident. The archaeological record provides evidence for the choices made by people in the past about the different forms of ceramic and glass vessels needed for specific practices. But can these typologies also lead us astray? Does the presence of the same shape always indicate the same method of use? Conversely, were the diverse vessel shapes produced by different traditions intended for use in common rituals – most obviously, wine drinking? This paper will explore these questions by examining patterns in individual and group choices about vessel types, using the Sibaritide region and the Timpone della Motta excavations

in southern Italy as case studies. I will argue that each vessel embodies the social, cultural, economic, and craft context in which it was produced and used.

4 LARGER THAN LIFE: USE AND FUNCTION OF SUPER-SIZED KANTHAROI IN BOEOTIA

Meens, Anna (University of Amsterdam)

In ancient times in Greece the kantharos was a drinking vessel which was used in symposia, as depictions show us, however kantharoi were also common in everyday life, as their frequent occurrence in household contexts demonstrates. The two-handled cups, usually black glazed, also occur in sacred and funerary environments. As the shape leaves the profane realm sometimes it undergoes a profound change in size: it becomes much taller and larger. One starts to wonder if such vessels were still intended to be used or if they have become symbolic attributes.

Kantharoi were especially popular drinking vessels in the region of Boeotia (Central Greece). This paper will focus on the functions of kantharoi in various (use?) contexts in Boeotia, and explore if the shape changes according to context and reflect on possible meanings. Who were using kantharoi as drinking vessels and for what reasons? Were some kantharoi even intended as drinking vessels?

5 ANALYZING ATTIC BLACK-GLAZED POTTERY FROM OLBIA PONTICA: A COMPARATIVE CHARACTERIZATION BASED ON DIFFERENT CITY AREAS

Chechulina, Iryna (The Institute of Archaeology National Academy of Science of Ukraine; Taras Shevchenko National University of Kyiv)

Pottery was an essential commodity in the ancient Mediterranean world, serving both practical and symbolic purposes, and traded over long distances. Attic black-glazed pottery, one of the most common materials in Olbia Pontica, was a highly standardized Greek ceramic product and undoubtedly one of the most important groups of pottery transported to the region. Its black gloss coating, a complex system of stamp ornamentation, and morphological features allow us to distinguish the type and subtype of vessels and to determine the dating, which in some cases may be narrowed down to a timespan of 10–25 years.

Based on mass archaeological findings and previous studies of Attic black-glazed pottery in Olbia, a comparative characterization can be drawn depending on different areas of the city. First and foremost, the following areas have been studied: the central residential quarters of the city, the northern sector in the Lower City, the eastern and western temenoi, and the Classical and Late Archaic necropolis of Olbia.

The entire spectrum of the pottery has been analyzed in terms of the popularity of different vessels, both open and closed shapes, and the type inside each group. This paper will focus on the distribution of the various drinking shapes. The (drinking) pottery distribution may be associated with various factors, such as socioeconomic conditions, cultural preferences, or functional requirements in different parts of the city. This comparative analysis provides insights into the patterns of usage, popularity, and distribution of Attic drinking vessels within the urban landscape of Olbia.

6 INNOVATION AND TRADITION IN THE CERAMIC SET OF THE ROMAN VILLA OF PATTI

Morganti, Mariano (Università degli Studi di Messina) - Giglio, Donata (Università degli Studi di Messina)

The selection of ceramic vases in antiquity often transcends mere functionality, embedding itself within a complex matrix of elements that encompasses tradition, aesthetic preference, and social dynamics. This study delves into the impact of social openness and market interactions on the diversity and spread of ceramic types within a society, underscoring the importance of introducing new ceramic forms alongside the persistence of traditional ones. Through the examination of evidence from the context of the Roman Villa of Patti, located on the north-eastern coast of Sicily, this work seeks to delineate the interplay between innovation and tradition in shaping the ceramic repertoire of a late antique domestic setting. The case study provides an exceptional view into the practices of adopting new ceramic types while concurrently maintaining traditional aspects, thereby offering profound insights into the dynamics of cultural transmission and the character of daily activities in light of the socio-economic and cultural backdrop of the period.

1040 TRACKING THE URBAN DNA. UNRAVELLING THE RISE AND FALL OF TOWNS AND CITIES

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Bouwmeester, Jeroen (Cultural Heritage Agency of the Netherlands) - Seppänen, Liisa (University of Turku) - Haase, Kirstine (Museum Odense) - Belford, Paul (Heritage Innovation) - Rieger, Dirk (Hansestadt Lübeck)

Session format: Regular session

Urban places are dynamic. They are hubs of networks, influences, economies, cultures and religions. Rome is an appealing example of positive urban dynamism: it originated as a small settlement and steadily grew into a world power, overshadowing other cities, territories, countries and even continents. Of course, not all cities went through such a development. Some declined quickly because of environmental, political or economic changes (or a combination of all of those). Each urban place developed and evolved in its own way, determined by an interplay of factors: the natural landscape, connectivity between the settlement and its region and beyond, political and economic support for the settlement, the right people in the right place who could allow urbanism to develop further, and the economic base of the settlement itself. Traces of this can be found in the city's DNA.

In this formal session of the EAA Urban Archaeology Community, we want to challenge contributors to track down this urban DNA.

- How did the different elements express themselves that are so decisive for the development of the settlement?
- What can we still find here, above ground and below ground?
- How did this determine the city's spatial structure over time and is it still recognisable?
- Can we recognise external elements that at some point started to leave their mark on the city?
- What are the challenges of recognising and exploring this DNA and what are the challenges of preserving these remains for the future?
- What happens to the DNA of failed settlements?

We welcome contributions from Europe and beyond that illuminate this theme, independent of specific periods and cultures, to highlight the topic from as many different perspectives as possible.

ABSTRACTS

1 SOBA - MEDIEVAL METROPOLIS AND A MEETING PLACE OF AFRICAN URBAN TRADITIONS

Drzewiecki, Mariusz (University of Warsaw)

Soba was the capital of one of the medieval kingdoms of Sahelian Africa. The remains are located on the right bank of the Blue Nile, approximately 20 km from the centre of Khartoum. It was the metropolis for Nubian rulers of the Kingdom of Alwa (approx. 6th–16th century CE). The ruins of Soba are currently considered one of the largest archaeological sites in Sudan.

Results of research conducted in 2019–2022 suggest that the spatial organisation of the medieval city has been changing throughout the millennium of its existence. In the first centuries, Soba might have been a polycentric city. Its urban development seems dispersed, with no single, clearly accentuated centre. There were, however, several localities with permanent settlement. Such urban organisation in western and southern Africa is interpreted as a result of development of communities where power was not in the hands of an authoritarian leader or lineage but was exercised by a larger group of individuals or families.

At the beginning of the 9th century CE, the city's structure started to change. New ecclesiastical and royal complexes were built reflecting patterns of centrally organised cities existing at that time in northern Africa. Communities inhabiting Soba might have undergone a significant transformation. At the same time, written sources suggest that around the 10th century, the kingdom of Alwa had close political ties with its northern neighbour, Makuria.

2 REGULAR URBAN LAYOUTS IN THE MIDDLE AGES: BETWEEN IDEAL CONCEPT OF FOUNDER AND ECONOMICAL REALITY OF URBANLIFE

Legut-Pintal, Maria (University of Wrocław) - Kubicka-Sowińska, Anna (Wrocław University of Technology) - Ćmielewski, Bartłomiej (Wrocław University of Technology)

The layout of a town is a puzzle that allows us to read its origins, development, and transformations. It is one of the core components of the city's DNA. In the Middle Ages, regular urban plans were typical for newly founded cities. The original planned scheme has undergone significant transformations and only partially has survived to the present.

In our project, we analysed spatial layouts of selected regular medieval towns in Central Europe, Tuscany and Occitania. The aim of the research was to reconstruct the original plan and answer the questions: To what extent does a city plan influence its development potential? Are social inequalities reflected in the city plan, land divisions, and size of plots? We used the cosine quantogram method, which allows identification of a basic module in a set of measurements. The method was used to analyse the width of plots, streets, and building blocks. Measurements were taken based on cadastral plans of cities and archival maps. Additionally, field survey were carried out using a mobile lidar system, which allowed us to obtain an accurate model of architectural objects. Where possible, we tried to combine the results with archaeological data.

The results form the basis for discussion on the transformations of the spatial structure of cities with a regular plan. They show that urban layouts were not only an expression of the ideological assumptions of the founders of cities, but also a reflection of the practical needs of the inhabitants. The changes that regular urban centres underwent were a consequence of adaptation to changing economic, political, and environmental conditions. The differentiation of urban space was a product of socio-cultural transformations.

3 URBAN LANDSCAPING – UNDERSTANDING STRATIGRAPHY AS MORE THAN WASTE MANAGEMENT

Haase, Kirstine (Museum Odense)

This paper will argue that the landscape is a fundamental part of the urban DNA. It is not just the natural environment and the settings shaped by ice and water, but the landscape modelled and altered by the people living in the city. Many European medieval cities have been shaped by removing and adding soil over centuries, resulting in what we now recognize as archaeological stratigraphy. This stratigraphy is often looked upon as the result of bad waste management and a more or less random accumulation of production waste, debris from demolished buildings or similar activities. This presentation suggests looking at the build-up as a conscious action caused by either the necessity to include formerly uninhabitable areas in the city as the population grew or to adapt the landscape to suit the citizens' or its lords' ever-changing demands and needs.

To further understand the process of urban landscaping, the paper will present a case from Odense in Denmark, where the urban landscape has been reconstructed at different points in time. This has enabled us to understand the reasons and motivations for the changes being made in the city's landscape and the physical development as more than changes in attitudes towards waste management.

4 TOWNS WHICH NEVER MADE IT: SOME EXAMPLES FROM WALES

Belford, Paul (Heritage Innovation)

The creation of new urban places was one of the defining aspects of the Anglo-Norman conquest of medieval Wales in the eleventh and twelfth centuries CE. Some Welsh historians have characterised towns as purely 'colonial' entities; however towns were also established by Welsh princes on the same model as their English counterparts. They had the same intentions: to create nodes for trade and economic growth, and to provide functions to support the administration of wider territories. Some of these towns were successful very quickly – but not all of these were resilient enough to survive the challenges of war, famine and climate change in the fourteenth and fifteenth centuries. Other towns grew slowly until the post-medieval period, and some never flourished at all.

Using data from thirty years of developer-funded excavations in towns across Wales, this paper will explore the 'urban DNA' of places that are on the margins of the urban experience. A town may have a legal charter – and a castle, market, mill and church – but how urban is it really when there are only a handful of permanent residents? What was the impact of these new urban places on the surrounding landscape? What was the balance between their symbolic role and their pragmatic role as centres of trade and social interaction? The paper will consider whether we need to re-think how we define 'urban' in order to answer these and other questions – not just in Wales, but in marginal landscapes across Europe.

5 BEYOND THE WALLS. EXPLORING THE URBAN LANDSCAPE AROUND THE CITY

Bouwmeester, Jeroen (Cultural Heritage Agency of the Netherlands)

The city and the countryside seem like two opposites. However, they are not. The urban landscape does not end at the walls of the city, but extends much further. Many functions in the surrounding countryside are inextricably linked to the city.

Agricultural functions also have a direct relationship with the urban settlement. Think of providing raw materials for various crafts and, of course, producing food. But there is much more happening, for example gallows, monasteries and mills stood there.

It is interesting to see what kind of functions these actually are. And can patterns be discovered in this and is there an explanation for the specific location? In recent years, based on 16th century maps by Jacob van Deventer of nine cities, an inventory has been made of which complexes can be expected around cities and where they are located. Subsequently, the research will investigate whether a useful model can be made from these.

The results will be presented in this lecture and it will be explained how they can also play a role within the archaeological heritage management of cities.

1043 OUT OF NEGLECT, INTO THE SPOTLIGHT. STRATEGIES AND GOOD PRACTICES FOR REDISCOVERING SITES WITH TROUBLED HISTORIES

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Pizzuti, Elisa (Sapienza-University of Rome) - Palazzini, Flavia (Sapienza-University of Rome; Royal Netherlands Institute in Rome - KNIR) - Bossolino, Isabella (CReA-Patrimoine, Université Libre de Bruxelles) - Monti, Dario (Université catholique de Louvain) - Casarotto, Anita (University of Groningen; Royal Netherlands Institute in Rome - KNIR)

Session format: Regular session

Countless archaeological sites worldwide suffer from neglect or a lack of study, yet the reasons behind this oversight are rarely related to their significance or informative potential. The urgency to rediscover these contexts is heightened by the possibility that they may have already experienced, or are at risk of:

- damage (e.g. complete or partial obliteration caused by factors such as increasing urbanization and construction projects; limited access and possible loss of integrity due to conflicts and political instability);
- data loss (e.g. absence of thorough research owing to academic biases or a lack of stakeholder commitment; artifacts and documentation dispersal in the post-investigation phases).

Frequently, the chance of conducting new fieldwork in these contexts is hindered by a shortage of funds or inaccessibility, and the opportunity to get fresh information lies solely in the analysis of data from past research. However, scholars engaged in this recovery may face several challenges. Issues like the scarcity of up-to-date or complete documentation and the difficulty of working with data frequently not collected by modern standards add a layer of complexity to the work. Nevertheless, the result is worth the effort. The retrieval aids in gaining a better insight into the sites and often starts a virtuous cycle, fostering awareness, creating a shared narrative for community identity, and leading to collaboration among institutions and local entities to ensure preservation. For instance, digital online portals for data sharing and citizen science could be a powerful tool in changing the current situation, improving territorial monitoring and safeguarding of cultural resources.

We welcome papers that share first-hand experiences in addressing "neglected sites" with troubled histories, without specific geographic or chronological constraints. The session aims to discuss best practices for managing recovery challenges and preserving these sites for the benefit of future society.

ABSTRACTS

1 NEW DATES FOR OLD: RE-DATING THE PICTISH BURIAL MONUMENTS OF SCOTLAND

Mitchell, Juliette (University of St Andrews) - Noble, Gordon (University of Aberdeen) - Hamilton, Derek (University of Glasgow)

Past excavations and analysis have been key to building a picture of early medieval burial monuments in Scotland, that suggested the practice took place over an extended period. However the material culture and radiocarbon dates that underpin this picture may have been faulty or erroneous, and these results make their way into the archives, the archaeological record, and form the basis for subsequent interpretations.

A targeted project obtained a suite of new radiocarbon dates on old material from the archives, reviewed the reliability of other dating methods, and traced the development of interpretations. Going back to first principles and using the archive data to generate new scientific data with new scientific analyses, including Bayesian analysis, allows us to challenge the interpretations and assumptions that figure so prominently in how we have understood early medieval burial monuments in the past. Combining archives with new scientific techniques allows a fresh look at the data and new interpretations to be made.

2 BIOMOLECULAR ARCHAEOLOGY AS A TOOL FOR REDISCOVERING THE CHIOMONTE-LA MADDALENA NEOLITHIC SITE (ITALY, WESTERN ALPS)

Monticone, Alessia (University of Turin) - Mazzola, Marlisa (University of Bologna) - Curci, Antonio (University of Bologna) - Panero, Elisa (Musei Reali Torino) - Spiteri, Cynthianne (University of Turin) - Cilli, Elisabetta (University of Bologna) - Luiselli, Donata (University of Bologna) - Demarchi, Beatrice (University of Turin)

An ongoing multidisciplinary project has the objective of rediscovering and rediscussing the finds from the Chiomonte-La Maddalena, a multi-period site in the Western Alps, near Turin (Italy). The archaeological materials were totally removed at the end of the excavations and are now part of a museum collection. The site was excavated in the 1980s as a rescue excavation and the abundant anthropological, faunal and ceramic material has never been fully studied. Chiomonte-La Maddalena is the only Neolithic site which has been found in the Piedmontese Alps to date, and therefore represents a unique opportunity to investigate human-environment relationships in a marginal upland area as well as the cultural exchanges that may have occurred.

An effort was done to rescue the scant and scattered excavation documentation, and to reconstruct the complex stratigraphy. In the 2000s, a pilot morphological study was carried out on the more diagnostic macrofauna, lithics and ceramics. We are complementing this with Zooarchaeology by Mass Spectrometry on the more fragmented faunal remains in the assemblage to identify resources utilised for subsistence. Results indicate that both wild and domesticated herbivores were being consumed and that fragmentary human remains were also present in the sample. The latter have been selected for radiocarbon dating. Targeted aDNA analyses has been carried out to clarify the phylogeny of some animal taxa. In parallel, lipid residues from Neolithic ceramic vessels have been extracted and characterised to identify subsistence patterns. Overall this study showcases the potential of biomolecular archaeology for reconstructing the biography of complex sites on the basis of data-poor legacy collections, but also testifies to the positive feedback loop which started with a major engagement of local partners and the Musei Reali of Torino.

3 DEALING WITH THE ARCHIVES ON ANTHROPOMORPHIC STELAE SITES IN SOUTHERN ETHIOPIA: A TURNING POINT IN SITES' CONSERVATION

Anne-Lise, Goujon (CFEE, Addis abeba; TEMPS, Paris Nanterre) - Vincent, Ard (CNRS, TRACES, Toulouse) - Antoine, Laurent (Toulouse University) - Aurélien, Pierre (Musée Fenaille, Rodez) - Sophie, Corson (Historial de Vendée, Lucs-sur-Boulogne) - Philippe, Gouézin (CReAAH, Rennes University) - Anne-Charlotte, Philippe-Lelong (Meganéo Association) - Sophie-Jeanne, Vidal (Atelier du Rouge-Gorge, Naucelle) - Ermias, Yeshitla (Woloytta Soddo University)

Ethiopia has one of the richest megalithic heritages in East Africa. Its origin and chronology have challenged researchers for almost a century. This presentation proposes to discuss the evolution of these sites through the rare archives available dating from the 1930' and 2000'. Methodological questions will be addressed, as well as ethical ones: is archaeology at the root of the dismantling of these sacred sites?

The site of Tuto Fela is today emblematic of the anthropomorphic stelae sites dating from the medieval period, located in the eastern foothills of the Rift Valley, and at the heart of what is the largest complex of phallic stelae sites. These megaliths were first described to the academic public in 1931, when F. Azais and R. Chambard published a book on their three exploration missions to southern Ethiopia between 1926 and 1929. Pursuing the work of these pioneers, a team led by A.D. Jensen documented the Tuto Fela stelae for the first time in 1934, providing a partial state of the site with 245 photographs, 38 drawings, and a report mentioning other sites.

In 2023, the implementation of a spatialized database of these stelae sites is undertaken by the Abaya archaeological mission. It is based on the inventories drawn up during the excavation campaigns led by R. Joussaume at Tuto Fela in the 2000s, while seeking to integrate ancient archives.

In addition to the difficulties involved in processing this archival corpus, with its gaps in data and its overlapping inventory of sites and stelae at Tuto Fela, we'll be looking at what extent GIS can be used to recreate the ancient distribution of stelae sites. In this way, we will attempt to write the history and measure the extensive dismantling that the region's archaeological heritage has undergone, at the same time as its enhancement.

4 IN FAVOUR OF AN ARCHAEO-HISTORICAL APPROACH TO STUDY OLD COLLECTIONS: THE EXAMPLE OF RAOUL DANIEL'S WORK ON THE TOURTOIRAC ROCKSHELTER

Vignoles, Anaïs (University of Liege) - Doyon, Luc (Université de Bordeaux)

Since the development of computational approaches and digital open data in archaeology, it became possible to gather huge amounts of data and analyse them via large scale statistical approaches. However, a critical posture must be adopted towards the quality of data that are being re-used, since they are produced in a specific historical and scientific context. A historiographic approach to archaeological data is therefore crucial to specify the terms of its reusability in our current paradigms. Here, we present an archaeological and historiographic study of Raoul Daniel

(1891-1978)'s finds at the Tourtoirac rockshelter, that he explored together with his father Jean in the early 1910s. The material comprises ca. 80 lithic and a dozen osseous artefacts, their associated markings and curation boxes, Raoul Daniel's archival fund (2 boxes) and his article published in 1932. Our analysis shows that pragmatically cross-examining these different sources is crucial to qualify and interpret the archaeological information for this collection, as they complement each other to contextualize the artefacts spatially and chrono-culturally.

5 THE POTENTIAL OF THE GRAZIOSI ARCHIVE FOR THE STUDY OF THE LATER STONE AGE OF THE HORN OF AFRICA

Mutri, Giuseppina (Unità di Archeologia preistorica, Dipartimento SAGAS, Università di Firenze, Firenze (Italy); University of Connecticut, Department of Anthropology; ISMEO) - Lo Vetro, Domenico (Unità di Archeologia preistorica, Dipartimento SAGAS, Università di Firenze, Firenze (Italy); Museo e Istituto Fiorentino di Preistoria, Firenze (Italy)) - Martin, Lavinia (Museo e Istituto Fiorentino di Preistoria, Firenze (Italy))

During the 1950s, the Italian archaeologist Paolo Graziosi conducted extensive research in Africa, with a particular focus on East Africa and the Libyan Sahara. Ethiopia, Eritrea and Somalia were the subject of surveys and excavations, which led to the identification of a rich sequence of prehistoric settlements dating from the Middle Stone Age to the Pastoral Neolithic. An important part of Graziosi's research in the Horn of Africa was dedicated to the Later Stone Age, period for which several surface stations and stratified sites have been identified, mainly rock-shelters. The excavations returned a large amount of lithic artifacts, animal and human remains and are preserved in the Museo e Istituto Fiorentino di Preistoria (MIFIP). They have been the subject, over the years, of investigations by several specialists and recently the Marie Curie Global Fellowship project, led by G. Mutri at the University of Florence and University of Connecticut, included archive materials in a study that is reconstructing environmental adaptation and livelihood strategies of LSA hunter-gatherers in the Horn of Africa.

The extensive documentation stored in the Graziosi Archive at the MIFIP, including excavation and survey reports, maps, pictures and geological descriptions represents the base-ground for this research, by offering the necessary details to understand the context in which the artefacts were found.

Going through the data of some stratified Somali sites (Bur Eibi, Eil, Darrod, Kuf-Kuf, Iadadale, Monai and Moga-discio), our aim is to provide an updated interpretation of the precious information collected by Graziosi.

6 BETWEEN NEGLECT AND COLONIALISM. DIGGING INTO THE ARCHIVES TO RECONSTRUCT THE HISTORY OF KAMIROS (RHODES)

Bossolino, Isabella (Université Libre de Bruxelles)

From 1912, the island of Rhodes was the focus of archaeological activities first by the Kingdom of Italy and then by Fascist Italy, when Italian troops took advantage of the distraction of the Ottoman army, busy on the Libyan front, and militarily occupied the Dodecanese islands within a few days. The site of Kamiros – located on the NW coast of Rhodes and rich in ancient monuments – immediately became a favourite among Italian archaeologists.

However, this was not the first time the area had been investigated: Several more or less institutional archaeological missions had already taken turns at the site in the second half of the 19th century, mainly excavating the cemeteries. However, the lack of serious documentation of the excavations and the disinterest of the excavators in those who had preceded them on site led to an accumulation of various interventions scattered over the area and uncoordinated: a fact that naturally hampered the global study of the research on the site from a modern and scientifically valid perspective.

This paper aims to illustrate, through a case study, some of the methods and tools used to try to shed light on the troubled history of one of the most interesting sites in the Aegean, which is greatly misunderstood by both scholars and the public, partly due to its complicated research history. The available materials and some of the strategies used to try to bring the site of Kamiros back into the scholarly discussion will be presented.

7 DUSTING OFF THE ARCHIVES: RECONSTRUCTING THE LEGACY OF THE LATE BRONZE AGE CREMATION CEMETERY OF TIMMARI (MATERA, ITALY)

Pizzuti, Elisa (Sapienza University of Rome)

In the early 1900s, D. Ridola and Q. Quagliati uncovered an urnfield on the slopes of Mount Timbro near Matera (MT, Basilicata). This discovery highlighted what was, at the time, and still is, one of the largest urnfields in Southern Italy. The excavation revealed 248 graves, now housed and displayed in the Ridola National Archaeological Museum in Matera and in the Superintendence Office in Taranto.

Numerous scholars have studied this site throughout the years, with further excavations in the 2000s uncovering another 32 burials. However, a comprehensive analysis of this context has never been conducted, and the necropolis has remained mostly unknown despite its importance in Southern Italy's Late Bronze Age evidence.

By revisiting past documentation, we have managed to reconstruct the research history of Timmari and restore access to information that was once lost. Indeed, the transition from a physical to a digital archive was a significant aim in information retrieval, primarily to reduce the risk of additional damage and loss. In fact, the recovery process revealed that the most significant loss of information did not occur during the excavation or documentation phases but rather during the conservation stage.

This paper aims to illustrate the methodological solutions we have applied to tackle problems associated with artefacts and documentation manipulation during the post-excavation phase (e.g. errors in the artefact inventory or unreadable labels) and also demonstrate how the information collected through the recovery of legacy data has enabled a detailed picture of the occupation history of the Timmari cemetery, thereby extending our knowledge in the funerary customs of Late Bronze Age societies.

8 REDISCOVERING THE PROTO-URBAN SITE OF COMO SPINA-VERDE (N. ITALY): CHALLENGES AND POTENTIAL IN ARCHAEOLOGICAL RESEARCH

Di Maria, Francesca (Sapienza - Università di Roma)

Many are the challenges faced by researchers to be able to rediscover a neglected site. This contribution will focus on the case study of the protohistoric site of Como-Spina Verde (Lombardy, Northern Italy): it is one of the large-scale settlements of the Early Iron Age Golasecca Culture (150 ha -proto-urban size- in the 5th cent. BC). Despite its importance, the site has faced numerous challenges, including neglect and unregulated urban expansion. From its initial discovery in 1875 to recent preventive archaeology efforts, the Como Spina-Verde site has been recognized for its enormous potential, underlined by the complexity of the infrastructural elements, and for the possibility of studying the relationship between the settlement and its cemeteries. Indeed, scholars have mainly focused on the study of the necropolis, leaving the settlement only sketchily studied. This lack of studies, aggravated by the urban expansion that damaged the site, hindered a comprehensive analysis and understanding of the proto-urban centre, somehow subject to a generic historical approach. To fully understand the dynamics, challenges and potential of the Como-Spina Verde site, it is essential to apply a well-defined archaeological methodological approach through a multi-scalar approach. This requires the examination of modern administrative changes and the review of 150 years of studies, which have produced an extremely heterogeneous documentation of settlement archaeological evidence, both quantitatively and qualitatively. The Author is tackling the evidence from the Como Spina-Verde settlement through an integration of specifically targeted OA databases, with the primary objective of standardizing data, as a crucial point for comprehensive analysis of a mass of bibliographic, excavation and remote-sensing data, generally lacking precise chronological attribution. Only interoperable and interconnected data can allow the management and reconstruction of the settlement evidence from such different sources, carefully averting possible loss of information.

9 THE ARCHAEOLOGY OF PRE-CLASSICAL ATTICA: METHODOLOGICAL OVERVIEW FOR THE CASE OF SOUNION AND LAURION

Silva Porto, Mariana (Humboldt Universität zu Berlin; Paris 1 Panthéon-Sorbonne)

For this paper I propose to outline the methodology of my project using as an example the preliminary results of the first of four regional case studies covered by my PhD. My project focuses on a re-examination of the known archaeological data for four peripheral territories of Attic peninsula in the period between the fall of the Mycenaean Palaces and the Cleisthenic reforms (1200 to 500 BC). It uses a 1:1 scale GIS and connected database to facilitate an archaeological, landscape-based reading of the territory at different scales (individual structures, sites, areas, and Attica as a whole). Through these, it seeks to place the archaeological material from all known published sources in as precise a topographical and stratigraphic context as possible. For this presentation I would therefore like to focus on the challenges and opportunities of using this type of data which varies from 19th century excavation reports, to recent reports from rescue archaeology and includes both incomplete data and data that has already been subject to more recent revisions. More specifically, I would like to focus on the area of Laurion, which contains two major Attic sites, the sanctuaries on cape Sounion and the long-lived habitation site at Thorikos. Although much has been written about these two important sites, studies of the wider landscape beyond them have tended to focus on the changes the area underwent from the late archaic period onwards. By assembling data from different periods for the wider Laurion area, I propose to consider its development in the preceding centuries, including its role in the growth and repopulation of the peninsula and its position within the growing Athenian sphere of influence.

10 THE THEATER AT AMITERNUM REDISCOVERED. NEW DATA AND FUTURE PERSPECTIVES

Trafficante, Ilaria (Scuola Superiore Meridionale)

The archaeological remains of the city of Amiternum (S. Vittorino, AQ) comprise two monumental poles, separated by the Aterno river. In both areas, the building typologies are for entertainment: the theater, on the left bank of the river, and the amphitheater on the right. The structures of the theatre, the subject of this paper, although brought to light at the end of the 19th century, were never studied nor was its architectural and sculptural decoration, today dispersed in various museums in Italy and the U.S.

Other problems made the study of this context particularly complex. First, we have completely lost stratigraphical data: the excavations of the 19th century were not carried out according to modern methodologies. Secondly, only general documentation of the architectural features and the materials brought to light is dispersed in several Italian archives. Furthermore, two "heavy" restoration interventions were carried out in the 1960s and the 1980s, without compiling further documentation.

For these reasons, I recovered all the graphic and photographic documentation that testifies to the state of the structure before the 19th-century excavation and previous to the renovations of the 20th century. Thanks to these documents, I first examined the architectural features of the building, chose some significant samples of its masonry, and followed this with the study of the architectural and sculptural decoration. A general plan of the building, based on new drone photomosaics, was finally vectorized. In conclusion, the building phases have been identified and dated according to the documentation recovered, and some hypotheses for the reconstruction of the decorative characteristics were proposed.

The lack of stakeholders and a complex institutional framework present us with a new challenge: how is it possible to publish the new data gathered and promote a new plan for conservation, valorization, and sustainable development?

11 THE INSCRIBED BLOCKS OF THE OLD TOWN OF ALULA : A MEANS OF STUDYING URBAN DEVELOPMENT

Louman, Laura (Archaios; PLACES; MSHST-CREAP) - Jacquemet, Jules (CIHAM; Université Lyon 2) - Vernet, Apolline (Archaios; Laboratoire Orient & Méditerranée - UMR 8167)

AlUla Valley, or wadi al-Qurra, lies in the northwest of Saudi Arabia and has been the cradle of early civilisations and famous kingdoms, such as the Lihyanite, Dadanitic, Minean and Nabateans. The most recent heritage asset of the valley is the Old Town, which has been under investigation by a multidisciplinary project, MuDUD, since 2021. Abandoned in the 1980s, the vast majority of the buildings composing this town are still standing. Their earth-and-stone masonries, dated back up to the 13th c., are partly composed of reused blocks, and most notably inscribed ones from the pre-Islamic and Islamic periods.

Almost 40 of these inscribed stones had already been recorded by explorers, sparsely allowed to enter the town during the late 19th-early 20th. They brought back an exclusive documentary fund made of squeezes, location maps, drawings, pictures and transcriptions. The systematic investigation of the Old Town by the MuDUD project allows the addition of more than 200 inscribed blocks to this epigraphic corpus, carefully recorded by means of photogrammetry, descriptions and transcriptions.

The recurring presence of these blocks and their spatial distribution within the urban fabric raises questions regarding stone economy, while their location in and outside the houses forces us to examine their uses as aesthetical elements. Finally, the variety of languages identified leads us to enquire about their provenance in and around the valley.

Through an in-depth epigraphic study and GIS analysis, these inscribed blocks unveil new evidence of urban transformation. This paper will present how merging archives documentation and current 3D modelling allows one to better apprehend the urban history of AlUla Old Town, and how, thanks to the implementation of a digital ecosystem, one is able to analyze the documentary resources linked to the project's latest acquisitions.

12 THE ARCHIVES OF ARCHAEOLOGISTS OF YESTERDAY. A HISTORY TO PASS ON! A SCIENTIFIC HERITAGE CHALLENGE FOR FUTURE GENERATIONS.

Faupin, Géraldine (Service régional de l'archéologie, DRAC Hauts-de-France, Ministère de la Culture; UMR HAL-MA 8164)

The history of French archaeology is a rich one, marked as much by different generations of archaeologists, as well as by important legislative developments. The archives associated with all the archaeological operations carried out on French territory (surveys, excavations...) are numerous, varied and stored in multiple places and with different statuses. Regional archaeology departments (DRAC, French Ministry of Culture) are responsible for collecting and managing these archives (paper and electronic).

Given the age pyramid, we are currently experiencing a key moment in terms of generational transition and the transmission of knowledge and know-how as several generations of archaeologists (“amateur” archaeologists and the first generation of professional archaeologists) are either in the process of retiring, sadly deceased, or the structures in which they worked are closing down (associations, municipal archaeological services, etc.). There is an urgent need to collect their archives before they are lost. The preservation of the scientific data they represent is crucial for the future, since archaeology destroys the object of its study and because archaeological research is built on the accumulation of data. Before even considering making these ancient archives available and their subsequent reuse, we must first ensure that they are collected, processed and curated for the long term. Today, more than ever, we are faced with these crucial scientific and heritage issues.

In order to achieve this objective, the Hauts-de-France Regional Archaeology Service has been leading an active work since 2020. This presentation will draw on experience of this mission, with concrete examples to back it up (collection of historical archives from various stakeholders, oral archives campaign, implementation of a backlog reduction plan, classification, research tools, curation, availability and promotion of collections).

13 **INTEGRATING AND SHARING OLD AND NEW: HATCH: HOUSE AT ÇATALHÖYÜK – A NEW DIGITAL REPOSITORY FOR THE WORLD HERITAGE SITE**

Filipowicz, Patrycja (Faculty of Archaeology, Adam Mickiewicz University)

Çatalhöyük is a World Heritage site in Türkiye that has been intensively excavated for more than a quarter of a century: first in the 1960s, and then after a 30-year gap in the framework of the large international Çatalhöyük Research Project until 2017. The excavation is ongoing, although on a smaller scale, and the field data is accumulating. Over the years, the project produced a wide variety of data of different characters. This poses many challenges for storing, maintaining, and sharing the data.

The members of the project team and IT specialists from Adam Mickiewicz University in Poznań have designed an open-access repository devoted to presenting major findings from this world-renowned site: HATCH – House at Çatalhöyük. It has the form of MIODEC—Multidimensional Interactive Open Digital Educational Collection, which is innovative software for creating and maintaining digital assets. HATCH presents systematically all buildings excavated to date (both Neolithic and post-Neolithic), along with burials and different finds found at them. It was designed as a didactic tool for the professional and lay public, presenting information in a systematic manner, both from old and recent research. In my paper, I intend to provide an overview of HATCH, in particular in relation to the use of archival information, presenting it to academics and laypeople, and integrating it with the ongoing scientific work at the site.

14 **DUTCH PIONEERING FIELD SURVEY IN ITALY: CAREL VAN ESSEN AND HIS “PASSEGGIATE ARCHEOLOGICHE” IN ROMAN LANDSCAPES (1947 - 1963)**

Casarotto, Anita (University of Groningen / Royal Netherlands Institute in Rome - KNIR) - Mente, Janet (Royal Netherlands Institute in Rome - KNIR) - Giofrè, Diana (Royal Netherlands Institute in Rome - KNIR)

The Van Essen Archive at the Royal Netherlands Institute in Rome (KNIR) forms a precious source of information to retrace the steps of Dutch field survey in Italy. Carel Claudius van Essen, vice-director and archaeologist of the Dutch Institute in Rome from 1947 until 1963, adopted the pioneering topographic survey method developed by the archaeologist-topographer Thomas Ashby (British School at Rome) to record important archaeological data in several Roman landscapes of Italy, which were soon after drastically transformed by modern urbanization, intensive agriculture or land use changes. These legacy survey data are important for two main reasons: because they allow for the reconstruction of the origins and historical influences of Dutch field survey methodology in Italy, and because they represent a unique cultural heritage to reconstruct archaeological sites and rural places that existed in the 1950s and 1960s, but then were damaged or completely destroyed by land transformations. In this paper a proposal for a future project in digital humanities based on geospatial mapping, territorial monitoring and modelling is presented that will rediscover archaeological contexts of the Roman and Italian countryside through the retrieval and promotion of the van Essen’s legacy archive (documents, book notes, postcards, negatives and photographs of his field surveys), thus breathing new life into “old” data. The aims will be to 1. study the origins, history and evolution of Dutch field survey methodology in Italy, 2. provide an heritage management instrument useful for landscape archaeology, local spatial planning and architecture, and 3. preserve the memory of forgotten rural places, traditional ecological knowledge and past agropastoral practices, thus reinforcing shared narratives for community identity of present and future society.

15 **“REDISCOVERING MUGILLAE ARCHAEOLOGICAL SITE”: A COMPREHENSIVE APPROACH TO URBAN PLANNING AND COMMUNITY IDENTITY**

Lollino, Walter (Università degli studi di Bari) - Fiano, Francesca Romana (Università degli studi di Ferrara)

Nestled into the Archaeological Park of the Appian Way, the settlement of Santa Maria delle Mole is a ‘dormitory town’ on the south outskirts of Rome. The urban fabric has developed under an uncontrolled speculation, ignoring its relationship with the surrounding landscape, one of the main cultural palimpsests of Rome. Its environmental and archaeological qualities have been the driving force in curbing overbuilding since the 1970s. Only in 2020 the annexation of the area to the Park territories put a halt to cementification, opening a new perspective for archaeological enhancement. Here the local community’s struggles in contrasting overbuilding claimed for the protection of archaeological heritage as the opportunity to gain more public spaces, while a sense of community, feeling of belonging and collective identity increased, linked to the hypothesis that the ancient city of Mugillae once existed here, developing during such conflictual years an imaginary historical identity. Where over two centuries ago was hypothetically located Mugillae, is now an urban void spared by overbuilding on which insist a roman cisterna, in between urban space and the archaeological and agricultural landscape. No archaeological traces of the ancient city are recorded here but a mapping of the several non-monumental evidences found in the area before and during the building expansion have played a decisive role in bringing “out of neglect” the archaeological heritage of the area. Exploring their typology, chronology and functional qualities, it defined a reference and the starting point for a design proposal. The paper aim to discuss the methodological approach that integrates archaeological analysis with landscape and urban quality assessment, while dealing with the imaginary Mugillae’s historical identity, and how the process led to design strategies and narratives for the site’s enhancement and a program to reinvigorate and foster community engagement through an holistic and sustainable approach.

16 **PIANO AND POGGIO DELLE GRANATE (POPULONIA, LI - ITALY): THINKING A VALORIZATION PROJECT FOR A RISK AREA**

De Pieri, Francesca (Sapienza University of Rome)

Populonia was a reference center for the territory of northern Etruria. The site presented a complex structure: the Acropolis on two hills, and a lower city in the Gulf of Baratti, including the production districts, the ports, and necropolises.

Following the numerous archaeological investigations, in 1998 the Archaeological Park of Baratti and Populonia was inaugurated, which currently includes the necropolar area of Podere San Cerbone and Casone, in the Gulf of Baratti, and the Acropolis area.

From this virtuous example of valorization, the nearby archaeological area of Piano and Poggio delle Granate remains completely excluded. It is an extensive necropolis in use from the early Iron Age until the beginning of the 3rd century BC. However, its existence has been put at risk since its rediscovery: in 1927 an invasive building renovation project was proposed in the area, and at present it is in a total state of decay and abandonment, which endangers the existence and conservation of the few archaeological remains still in situ, inconceivable if you consider that the reality of the Archaeological Park is just a few steps away.

Now more than ever it seems necessary to think of a valorization project that also includes this area, both to be able to safeguard it, and to be able to return this piece of history to the local community. After some preliminary survey to verify the state of the site, the first protection actions made use of modern technologies, in particular GIS, to carry out a census of the ancient evidences and that which are still present. The analysis of previous participatory archeology projects has instead made it possible to ascertain the needs and desires of the local community to arrive at a preliminary proposal for some possible interventions to enhance the site.

17 **DIGITAL HERITAGE AT THE DISAPPEARING ISLAND: A HOLISTIC APPROACH TO ENDANGERED COASTAL HERITAGE**

Harrison, Laura (University of South Florida) - Hansen, Kimberly (University of South Florida) - Fernandez, Steven (University of South Florida)

In 2019, the Florida Trust for Historic Preservation listed Egmont Key as one of the state’s 11 most endangered heritage sites. The 2 km² barrier island has lost nearly half of its landmass in the last 150 years, submerging several heritage sites, and endangering numerous others. Few of the island’s 200,000 visitors per year are aware of the island’s rich history or the threats it faces, due to inadequate tourist interpretation and visitor infrastructure. This presentation discusses the process behind creating high-resolution simulations of the projected impacts of rising sea levels on coastal heritage, with a novel combination of terrestrial lidar, aerial lidar, and GIS. These analyses help advance communication between academic researchers and local land managers, who must decide if, when, and how to address the problem of beach erosion and historic preservation, despite limited resources. These simulations inform recom-

mentations about the implementation of living shorelines, green infrastructure, and targeted beach renourishment. The goal is to promote sustainable tourism and protect the island's natural and cultural heritage in accordance with the UN Sustainable Development Goals (Targets 8.9 and 11.4).

Digital tools such as augmented and virtual reality enhance community engagement with these goals. Outreach programs include: (1) a virtual reality experience that reveals how overlapping natural and anthropogenic factors threaten to wash away history; (2) a Heritage Monitoring Scouts citizen science program; (3) a Guardians of the Gulf augmented reality app for children that uses animated trackers to gamify cultural heritage preservation, and (3) a Step into History place-based augmented reality app that brings the island's "ghost town" to life with digital reconstructions and first-person historical narratives. Together, these public heritage tools weave together geoinformatics with broader digital storytelling projects that will live on, even if the island itself disappears.

18 "DISAPPEARING INTO THE FOREST" - ATTITUDES TOWARDS WW II PLACES USED BY FINNISH MILITARY DESERTERS

Kauhanen, Riku (University of Turku, Finland)

During Finnish Continuation War (1941–1944) thousands of Finnish men refused to go to fight in frontlines, and many fled to wilderness where they stayed hidden from officials in improvised campsites. After the war most of the sites that survived the war without being located and destroyed by officials were mostly forgotten in public memory, but some gained later interest of locals because of their dramatic history which included firefights, accusations of atrocities and strong, continuing political differences. Even though these sites could be considered as "difficult heritage" some sites were and are used to discuss the actions and treatment of members of Finnish resistance movements during Second World War.

Many sites have already disappeared through forestry or natural decay, without any realistic possibility to locate and study them any longer. Their "young age" also means that they are not automatically protected by laws, so raising interest and sharing knowledge is key to try to further study and preserve them. Interest towards these sites is not always a blessing or guarantee that they are protected in sustainable way or in a way that stores the "spirit" of the place. When some site gains more interest through publications or media, there is possibility that locals and officials start seeing the place as tourist attraction and alter the site to meet the expected needs of travellers.

In this paper I will highlight two places that gained strong local interest in 1980s, how that changed the places and what this means for archaeological research. I also discuss the research possibilities of these campsites, when the places are "forgotten", known only to surviving family members of deserters and local historians.

19 THE ERASURE OF THE SLAVIC MATERIAL PAST OF GREEK MACEDONIA

Stavridopoulos, Ioannis (Independent researcher)

Greek Macedonia became part of the Greek state in 1912-13 as an outcome of the Balkan Wars. In this period, Muslims, Greeks, Slavic speakers, Jews, Vlachs and Gypsies composed the populational mosaic of the area. During the 20th century, most of the non-Greek populations fled. The Slavic speakers, in the beginning of the 20th century, constituted a great part of the population of the area. After the absorption of the area and for many years, the Greek state regarded the Slavic speakers as a potential enemy, a group of people that they had to be either integrated or expelled. Throughout the 20th century, the Greek government inflicted different measures for their assimilation. Many were tortured, imprisoned, exiled, and expelled from the country. They lived for decades under constant surveillance and suppression by the authorities. A central issue in the state assimilation efforts was their language which was banned. Slavic inscriptions were erased, painted over and destroyed. Most of them were in churches, on icons, murals, religious books, tombstones and bells. In a few cases, even whole churches were demolished condemned as Slavic. The destruction of the Slavic material traces was used in the forced Hellenization of the area.

In my paper, I will focus on this group of monuments still a taboo for Greek academia and the state services. By using different examples of destructions collected through systematic field research, I will attempt to shed light on the erased material memory of the Slavic speakers of Greek Macedonia. I will also try to document the history of the monuments lost and to record the surviving ones. My aim is to make these monuments visible, a first step towards their acceptance, preservation, and protection by the local communities and the state authorities as part of the area's cultural heritage.

20 DOCUMENTING THE REMNANTS OF ITALIAN RULE IN NORTHERN DALMATIA, CROATIA: A HISTORICAL, CULTURAL, AND POLITICAL CHALLENGE

Iglic, Sara (University of Zadar)

Remnants of modern conflicts are frequently found in Croatia, but they have not been extensively researched archaeologically, except for a few exceptions. The purpose of this paper is to explore the difficulties of documenting

the remnants of Italian rule in northern Dalmatia in the first half of the 20th century. These remnants, which include military bunkers, barracks, defence lines and camps, can often be a source of ideological controversy, especially if neglected after recent conflicts and occupations. As a result, documenting these sites requires a careful examination of their historical, cultural, and political importance. Due to urbanization and construction, the traces of Italian rule in the region are being destroyed without proper archaeological documentation. Therefore, historical photographs and documents together with amateur research are relied upon to properly document and research these sites before they are more severely neglected and destroyed. Only a small part of these remnants were documented archaeologically, and the rest is now being irreversibly damaged by increasing human pressures. To ensure that the next generations can learn from history and appreciate the significance of past events, it is crucial that we take necessary measures to document and research sites that hold contested pasts. By documenting and, if possible, preserving these sites, we can gain a deeper understanding and appreciation of our shared history, and ensure that the lessons of the past are not lost to time.

1044 WHAT A WASTE! ? THE EPISTEMOLOGICAL VALUE OF REFUSE AND DISCARDED MATERIALS IN THE CURRENT ARCHAEOLOGICAL RESEARCH

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Cereda, Susanna (University of Innsbruck, Institute of Archaeologies) - Zambaldi, Maurizio (University of Coimbra, Centre of Studies in Geography and Spatial Planning (CEGOT), FLUC, Department of Geography and Tourism) - Jakobitsch, Thorsten (Austrian Archaeological Institute/Austrian Academy of Sciences, Environment and Human Impact in Historical Societies)

Session format: Regular session

Understanding the past through the material remains of human activity has always been a prime pursuit of archaeology. More than architecture, artistic productions, grave goods, caches, or offerings, societies have left behind throughout history a trail of waste: unwanted artefacts and materials that were intentionally (or unintentionally) disposed of. Despite their ontological status of neglected things—or perhaps also because of it—they bear even higher potential as rich repositories of the past.

This session seeks to explore the epistemological value and research insights that waste, in all its forms, can offer to our understanding of human history. Reconstructing the hidden narratives behind refuse, middens, and dumps can redefine our approach to archaeological inquiry and specific aspects, such as: resource consumption, economic practices, social structures, value and identity construction, ecological interactions and more. We encourage papers that promote discussions on theoretical frameworks, case studies and cutting-edge methodologies, which can highlight the significance of the practice of discarding materials and their role in comprehending the complex and meaningful dynamics of human actions. History teaches us that waste generation and accumulation know no bounds, and that its impact on our planet has steadily increased over time. Consequently, we welcome contributions from all geographical regions and periods ranging from early prehistoric societies to ancient and modern urbanizations and the industrial world. The aim is to promote an interdisciplinary discussion among archaeological sciences (e.g., geoarchaeology, zooarchaeology, archaeobotany), ethno- and experimental archaeology, and material culture approaches.

Purpose of this session is to explore the untapped potential concealed within to refuse as we delve into its historical significance and reassess the criteria that determine what qualifies as "valuable" archaeological data.

Do not waste this opportunity!

ABSTRACTS

1 REFUSE/RESIST: REASSESSING THREE MESOLITHIC "MIDDEN" SITES ON THE EAST COAST OF IRELAND

Moucheron, Martin (School of Archaeology, University College Dublin; Irish Research Council Government of Ireland Postgraduate Awardee) - Gilhooly, Bernard (National Museum of Ireland, Irish Antiquities Division) - Onfray, Marylise (Institut National de Recherches Archéologiques Préventives - Bretagne, UMR6554 LETG) - Trafford, Andrew (iCrag - Research Centre in Applied Geosciences, University College Dublin) - Warren, Graeme (School of Archaeology, University College Dublin)

This paper presents the results of a PhD research dedicated to reassessing three Late Mesolithic sites on the east coast of Ireland – Sutton and Dalkey Island, Co. Dublin; Rockmarshall, Co. Louth. These sites, excavated between 1946 and 1970 and often grouped under the shorthand "Mesolithic shell middens", were formative in establishing the contours and identity of the Late Mesolithic in Ireland and are still considered part of the canon for the period (e.g.

Woodman 2015). However, this legacy obfuscates a dearth of reliable data about the sites which betrays the archaeological thinking, standards, and practices of their time.

The research project aimed to establish a state of contemporary knowledge about these three sites, and to explore their remaining archaeological potential. This double objective was carried out by looking at the existing archives, and by implementing a strategy combining multiple, non- or minimally-invasive geophysical and (geo)archaeological methods. The results reveal a contrasted state of preservation across the three sites, and highlight the strengths and limitations of the selected methods applied to a particular context.

More broadly, they underscore the formative effects of language and scale on the perception and construction of the Mesolithic in Ireland in the archaeological discourse - with “midden” a prime example that positions cultural layers in the semantic field of waste. This interpretive framework affects archaeological research practices; ideologically, it chimes with colonial, neoliberal constructions of hunter-gatherer groups, past and present, as non-productive non-agents representing an earlier and less achieved state in human evolution. By refusing “refuse”, we can resist the dominant discourse, propose an alternative narrative, and contribute to shift archaeological perception and practices about these cultural traces left behind by past people.

2 WASTE AND BEHAVIOR: LBK SETTLEMENT IN FOCUS

Pilar, Daniel (AU - Institute of Archaeology of the Academy of Sciences of the Czech Republic; Charles University, Prague) - Kvetina, Petr (AU - Institute of Archaeology of the Academy of Sciences of the Czech Republic) - Denis, Solene (French National Centre for Scientific Research)

The settlements of the Linear Pottery Culture (LBK) have been a major topic of research on the Early Neolithic (5500-4900 BC) in Central Europe for almost a century. However, despite many years of research, we are still unable to fully answer the fundamental questions of how these settlements were formed, which limits any research focused on, for example, chronology or socio-economics. Therefore, the study of taphonomy and waste management is in this context crucial. This paper presents a case study focusing on waste management at the LBK settlement in Hlízov (Czech Republic). The study analysed the fragmentation, refitting, and concentration of artifacts in the pits surrounding house-ground plans. The results indicate that waste management was much more complex than previously thought. It was found that each type of waste (pottery, chipped stone, ground stone) seems to be treated differently by Neolithic people. The case study shows that without waste management and taphonomy research, our understanding of everyday life at the settlements could be misleading and over-optimistic. The examined finds provide authentic testimony of human behavior in relation to waste management in the settlement space that constitutes a prerequisite before dealing with more complex issues like socio-economics, households or identity of the Neolithic communities.

3 WATERLOGGED MIDDENS INVESTIGATED THROUGH ARCHAEOBOTANY AND ARCHAEOENTOMOLOGY - THE CASE STUDY OF THE NEOLITHIC PILE DWELLING MOOSWINKEL IN AUSTRIA

Jakobitsch, Thorsten (Austrian Academy of Sciences)

Stable manure preserves well in waterlogged archaeological sediments. The organic refuse provides a wealth of information about the site's economy, forest resources, and impact on the environment. However, the recognition of middens and manure in sediment layers is not always straightforward. In the case study of the Late Neolithic pile dwelling Mooswinkel at the lake Mondsee in Austria, dung, botanical macro- and microremains, as well as invertebrates identified the sediment as stable manure from goat, sheep and cattle farming. Furthermore, the season of the layer formation could be recognized. Materials investigated included pollen, bryophytes, plant fruits and seeds, leaves, branches and bud scales of woody plants, as well as insect remains. In addition, plant microremains in dung were analysed. The results of this multi-material study show that leaf hay and grass hay were used as fodder during the winter season. The impact of fodder acquisition and pasturing on the forest could be reconstructed, showing the formation of a mosaic landscape of natural and semi-natural habitats.

4 WASTING TIME EXAMINING THE WASTE? THE EARLY BRONZE AGE WASTE FROM THE HOSTY SETTLEMENT (CZECH REPUBLIC)

Hlásek, Daniel (Institute of Archaeology of the Czech Academy of Sciences, Prague) - Kovárník, Jaromír (University of South Bohemia in České Budějovice, Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses) - Ernée, Michal (Institute of Archaeology of the Czech Academy of Sciences, Prague)

The primary focus of settlement archaeology often revolves around the examination of refuse. This comprises qualitatively and quantitatively transformed material remnants of past activities within a given settlement. Hosty settlement represents a typical prehistoric Central European dry site, notable for its exceptional preservation of cultural layers. The prevailing finds predominantly consist of fragmented pottery. A thorough investigation of this significant Early Bronze Age site, which evidences long-distance trade, metallurgy, and warfare, necessitates an exploration of non-typological aspects of the pottery. We have designed a method employing scanning and image analysis within the ImageJ Fiji environment, which efficiently measures various parameters of individual pottery fragments, such as area, maximum length, and shape regularity. Given the substantial volume of finds (approximately 200,000 sherds), operational efficiency is paramount. We contend that these data will facilitate a comprehensive examination of the transformational history of each find assemblage, crucial for elucidating their chronology and depositional context. Simultaneously, these data allow scrutinizing the waste area itself as a distinct archaeological source. Are we acquiring adequate information through this approach?

5 SECONDARY REFUSE OR REUSED OBJECTS? THE PRESENCE OF WASTE-LIKE MATERIALS IN THE FINNISH IRON AGE CAIRNS

Salomaa, Sanni (University of Turku)

Waste-like materials such as pieces of broken pottery, animal bones, stone flakes, burnt clay and slag are an essential part of many Iron Age cairns (c. 500 BCE -1200 CE) in Finland. Traditionally, the cairns have been interpreted first and foremost as grave monuments, and the curious occurrence of these fragmented materials has not yet been fully considered.

These kind of materials in the cairns can be found both with or without human bones or metal artifacts, concentrated in certain places or scattered around, and their presence is not easy to explain. Grave goods, votive gifts, or just plain waste – the interpretations of the materials have either highlighted the cairn as a grave or rejected it as ritual space altogether, in a very dichotomous way.

Through case-studies from Western Finland, this paper discusses the waste-like materials in the cairns on their own right. By examining the finds from previous excavations and their placement in the cairns with the help of geoinformation techniques, results from osteological analyses, and radiocarbon dating, the formation processes and meanings of the materials are reconsidered. The cairns are seen as places of possible multifaceted and long-term use, where presence of a burial does not exclude other kinds of actions. More detailed analysis of fragmented, seemingly valueless materials present in the purposefully laden constructions helps to understand the way Iron Age societies in Finland valued, reused and discarded materials cumulated by everyday life.

6 ROMAN LANDFILLS AS TWOFOLD ECONOMIC INDICATORS: PRESENCE AND ABSENCE OF ARTIFACTS IN AQUILEIA AND POMPEII

Furlan, Guido (UniPd)

Roman dumps are precious proxies of urban activities over potentially long periods. Their full potential, however, cannot be fully exploited without careful consideration of local formation processes, discard strategies, and possible biases.

When all these factors are modelled, waste assemblages can be profitably employed to investigate ancient economic dynamics. In this sense, hermeneutically, they have a twofold value. On the one side, the finds recovered can provide a reliable picture of economic fluctuations, particularly in terms of consumption and imports of ceramic vessels and related products. On the other side, just as significantly, proper consideration of what is missing reveals recycling strategies and circular economies on an urban scale.

These two aspects are investigated through two case studies. The first one is the infill of a suburban canal in Aquileia, employed as a dumping site between the late republican age and the mid/late imperial period. A re-evaluation of formation processes combined with the statistical analysis of the assemblage enabled to date the infrastructure and to investigate consumption and trade patterns through time.

The second case study is a peri-urban dump from Pompeii, which was still in use before the 79 CE eruption. In this case, a comparative approach highlighted the effectiveness of the local system of glass and metal recycling, shedding light on practices of circular economy. Archaeometric analyses have recently confirmed this picture.

7 HOLY WASTE: A MULTI-ANALYTICAL APPROACH TO THE STUDY OF CULTIC DEPOSITS IN THE COPPER MINE OF KROPFSBERG (NORTH TYROL, AUSTRIA)

Cereda, Susanna (Institute of Archaeologies, University of Innsbruck) - Staudt, Markus (Institute of Archaeologies, University of Innsbruck) - Goldenberg, Gert (Institute of Archaeologies, University of Innsbruck) - Tropper, Peter (Institute of Mineralogy and Petrography, University of Innsbruck) - Degenhart, Gerald (Department of Radiology, Medical University Innsbruck)

Kropfsberg, located by Reith im Alpbachtal (North Tyrol, Austria), is a dolomite mound that has been exploited for its copper ores since at least the Early Iron Age. Excavations conducted in 2020 by the University of Innsbruck exposed in detail the stratigraphic sequence of the mine, leading to a surprising discovery: what was thought to be merely a site for mineral extraction revealed a phase of use during the late Roman period with strong ritual connotations. The identified layers are characterised by abundant charcoals, animal bones and hundreds of votive coins, suggesting that the mine may have been used as a Mithraeum for some time.

Through micromorphology, μ XRF and CT analyses of the archaeological sediments, coupled with the precise spatial positioning of the recovered coins, we were able to accurately reconstruct the processes that led to the deposition of these layers and piece together the history of the cultic cave. While some of these remains indicate activities related to ritual burning ceremonies, others suggest the intentional obliteration of the cultic practices by later visitors of the mine. These findings prompt a reflection on how the label “waste” is attributed to materials in various chronological and cultural contexts. What defines waste—what is unwanted, dangerous, or tainted—and for whom?

Moreover, this study highlights the key role of microarchaeological and archaeometric analyses in uncovering variations in significance and value. These methods allow to reconstruct in greater detail the “context”, that is the sedimentary environment in which archaeological artifacts are embedded and ultimately found. Only through the careful analysis of these contextual details can archaeologists seek to comprehend the cultural significance of objects and gain a glimpse into the values of the past.

8 WHERE IS THE WASTE? THE MULTIENVIRONMENTAL STUDY OF THE DISTRIBUTION OF KITCHEN WASTE IN CASTLE ROKŠTEJN, CZECH REPUBLIC

Lisá, Lenka (Institute of Geology, Academy of Sciences of the Czech Republic) - Fišáková Nývltová, Miriam (Masaryk University, Czech Republic) - Kočárová, Romana (Masaryk University, Czech Republic) - Kočár, Petr (West Bohemian University in Pilsen, Czech Republic; Institute of Archaeology, Academy of Sciences of the Czech Republic) - Mazáčková, Jana (Masaryk University, Czech Republic) - Žaža, Petr (Masaryk University, Czech Republic)

The term waste is usually used to unwanted material that is permanently and intentionally thrown away with no further plans for its use. The kitchen waste should consist of the organic and organo-mineral residues from the food preparation and the food consumption. Are we able to track the distribution of the kitchen waste inside the medieval castle? To find an answer for this question a long-term archaeological excavation was done in medieval castle Rokštejn, Czech Republic which lasted between 1289 – 1467 years AD. The excavation area covers the 80 % of the inner castle and includes the space in the surrounding of the castle’s kitchens or bakery. As the castle was constructed in many stages, there was possible to compare two different areas linked to the food production in time and space and compare them with the other types of the waste or occupational surfaces. The methods of osteology, archaeobotany and micromorphology were applied to study archaeological material.

The typical dumping areas were not documented in the inner castle in spite of the fact, that the castle lasted for in minimum 270 years, and we can expect, that in minimum of 15-20 people of the great margravian court lived there permanently. A part of reused kitchen waste was detected in small castle’s garden areas. The bones are always cut, chopped, and crushed into small pieces and usually the hardest parts of the animal body like teeth or horn appear in archaeological record. These sediments are also often rich of charcoal. The micromorphology revealed accumulations of charcoal and eggshells in floor layers. The rest of the kitchen waste was perhaps transported out of the castle, decayed in dump areas together with the animal excrements and later distributed as fertiliser to increase crop yields.

9 TRACING URBAN PRACTICES THROUGH LATRINE WASTE - AN URBAN-ECOLOGICAL PERSPECTIVE ON LIFE IN RENAISSANCE COPENHAGEN

Mayer, Simone (Museum of Copenhagen) - Rosenkvist, Zenon (Museum of Copenhagen) - Dahlström, Hanna (Sydsvensk Arkeologi)

Latrines are common structures found on urban excavations throughout Europe and beyond. Due to lack of economic resources in rescue archaeology, it is rare that their full information potential is met. With our case-study of latrines from Renaissance Copenhagen, Denmark, we wish to draw attention towards the knowledge of past life which may be gained through close contextual and interdisciplinary analyses of latrines and their waste.

Our case stems from a research project focusing on the material manifestations of depositional practices and spatial organization of a backyard in 16th-17th century Copenhagen. With a point of departure in post-humanism and social practice theory defining the city as bundles of practices connected by intentional and unintentional acts; the construction, placement, and filling of latrines reveal narratives of everyday life during the period.

The latrine fills were examined with a combination of archaeological, historical, and scientific analyses looking at animal bones, macrofossils, insects, parasites, and soil micromorphology, allowing the ecology of the local backyard with its plant growth, animal presence and household activities to be traced. The results indicate intention and knowledge behind the deposition of different kinds of waste. Likewise, the emptying of latrines and the recycling of materials was investigated. Waste was not a dead good but had a prolonged and meaningful lifespan being used as landfill, manure or to enhance chemical processes inside the cesspits: The insertion of small amounts of kitchen waste to the latrine fill was intentional and based on knowledge about decomposition processes and sanitation. These examples indicate deliberate strategies adapting to a changing urban environment.

Our studies show that latrines, when investigated in a high-definition manner, hold significant information of urban people’s intentions, strategies, and values in an environment where lack of space and increasing economic interdependence demanded adaptation and resilience on a household level.

10 WASTE MANAGEMENT IN AN EARLY MODERN NORDIC TOWN THROUGH POTTERY RESEARCH

Helamaa, Maija (Muuritutkimus Ltd.; University of Turku)

This paper studies the waste treatment in an early modern (c. 17th–19th C.) urban environment through contextual pottery analysis of a recent large-scale excavation in Turku. When excavating postmedieval urban sites in Finland, pottery sherds can be found almost everywhere. Some ceramics is collected from distinct waste deposits, but majority of the material comes from different types of contexts. Fragments are found in fills and levelling layers, construction, and deconstruction layers, as well as scattered in the courtyards, and so on. Apart from the clear destruction layers and deposits of ritual purpose, for example, urban archaeological pottery is usually discarded although a single sherd may have gone through a complex process to its final resting place.

To understand how all the pottery is found where it is, the waste management of an early modern town needs to be addressed. Waste pits are rare in Finnish postmedieval archaeology and there is both archaeological and written evidence of the waste being transported and soil being moved around. In addition to scarce primary waste deposits, the scattered finds need to be taken account to discover the variety of the material, and to better understand the overall pottery consumption. However, the nature of these different types of discarded ceramics must be considered, for example how representative these secondary or tertiary deposits are, and what levels of information different groups of ceramic waste may provide.

This study is a part of ongoing doctoral research. Pottery in early modern (c. 1650-1830) Turku is studied to understand the everyday life of the people and their relation to the use of ceramics in different occasions and for various purposes. In addition, their attitudes towards broken objects as well as waste in their own area of living is considered.

11 THE CURIOUS CASE OF COLD WAR GARBAGE PITS AT ABANDONED SOVIET TACTICAL NUCLEAR BASES IN POLAND

Kiarszys, Grzegorz (The University of Szczecin)

In February 1967, the construction of three Soviet tactical nuclear bases commenced in North-Western Poland, sanctioned under the clandestine codename Wisła. Construction concluded in December 1969, and facilities were handed over to Soviet troops. Afterwards, the historical record in the Polish archives fell silent for the subsequent 22 years, until October 1990, when withdrawing Soviet troops abandoned the bases.

Throughout the conducted research, diverse non-invasive methods were employed to document remnants of the deserted Soviet nuclear bases. The primary objectives were to create comprehensive plans of the scrutinized facilities and decipher their spatial arrangements. The wealth of collected evidence significantly bridged gaps in archival records, unveiling insights inaccessible through historical documents. However, while the narrative derived from applied remote sensing techniques appeared comprehensive, it was also completely superficial as it lacked an essential

component – the daily lives and experiences of the soldiers and officers inhabiting these secretive compounds, the main ‘actors’ of this ‘drama’.

Throughout subsequent field surveys, numerous small garbage dumps were discovered within all three bases. Their contents posed a puzzle, as some elements seemed incongruous within the broader context. Alongside rugged fragments of Soviet uniforms bearing missile and artillery unit insignias, golden buttons featuring the hammer and sickle, military berets, gas masks, cans, and bottles, peculiar items surfaced: children’s boots, plastic toy remnants, women’s shoes, and other civilian female garments. The origin of these items raised questions – how did they come to be there? Declassified documents from the Wisla files bluntly recommended that all wives and children should reside preferably in larger Soviet garrisons distanced from the nuclear facilities, due to counterintelligence cover and a scarcity of living quarters.

The proposed presentation will discuss how discovering even small and seemingly meaningless artefacts can profoundly alter our interpretation of the entire subject of study.

12 DON'T THROW IT AWAY! MODERN WASTE, DISPOSAL PRACTICES AND A LOT OF PLASTIC

Waldhart, Elisabeth (University of Innsbruck)

There is almost no place where modern rubbish is not part of the upper soil layers. Respectively modern waste is part of many archaeological excavations and investigations, but it is rarely considered a valuable resource for scientific research. On the contrary, it is seen as an environmental problem! Furthermore, the things that are considered rubbish were thrown away for various reasons by the people who owned them at some point and therefore also subject to certain disposal practices. Looking at objects from the last 100 years that are deemed to be garbage raises a problem: Considering these items as “archaeological finds” is limited to the last few decades and mostly to archaeologists of the contemporary era. Accordingly, they are ladled as trash on site and often thrown away a second time instead being taken to the finds-lab.

What all these statements have in common is that the category of waste is imposed on things in social contexts, it is based on rules and practices that relate to the objects. Labelling something as rubbish is a means of establishing and maintaining (social) order. By looking at various case studies from Austria, I would like to sketch out some lines of what waste – as a social category, but also as matter that is entangled with its environment – can tell us about the society that left it behind.

1046 EVOLUTIONARY APPROACHES TO ARCHAEOLOGICAL QUESTIONS: HUMAN BEHAVIORAL ECOLOGY AND CULTURAL TRANSMISSION THEORY

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Yaworsky, Peter (Aarhus University) - Miu, Elena (Aarhus University) - McCool, Weston (University of Utah)

Session format: Regular session

Archaeology is the study of human behavior through its enduring material record. As such, it is important that we develop general understandings of human behavior and how people respond to changes in both the natural and social environments. Advances in archaeological methods and analytical tools have greatly enhanced our ability to describe the archaeological record. However, big data approaches and cutting-edge modeling tools may yield little explanatory power unless coupled with general theory, as atheoretical approaches generally struggle with framing questions, deriving predictions, overcoming issues of equifinality, and making inferences beyond direct analogy. A general theory of human behavior is needed to overcome these persistent issues. Two promising evolutionary approaches to understanding variation in human behavior and the material record are Behavioral Ecology (BE) and Cultural Transmission Theory/Dual Inheritance Theory (CTT/DIT). Both draw on evolutionary concepts to derive and test hypotheses using archaeological data to understand past human behavior, with important implications for the present and future. BE generally explains behavioral variation as adaptive responses to variations in the environment and is agnostic about the mechanisms involved (i.e., genetic, cultural). BE concludes that the behavioral diversity observed in humans is a direct result of the diversity in contemporary socioecological environments. CTT/DIT holds that both genetics, culture, and the natural environment influences human behavior, and that culturally and genetically inherited information are acted upon by evolutionary forces and structure human behavior. BE and CTT/DIT are often juxtaposed, but there is an opportunity to synthesize the two into a pluralistic discipline focused on the evolutionary study of human behavior to overcome the domain specific limitations of both. In this session, we highlight BE and CTT/DIT archaeology research to demonstrate their utility, facilitate discussion, and advance archaeological theory by pursuing their synthezation.

ABSTRACTS

1 EVOLUTIONARY APPROACHES TO ARCHAEOLOGICAL QUESTIONS AND THE IMPORTANCE OF THEORY-DRIVEN RESEARCH

Yaworsky, Peter (Aarhus University; University of Copenhagen) - Miu, Elena (Aarhus University) - McCool, Weston (University of Utah)

While anthropologists study human behavior through direct observation, archaeologists are limited to observations of the material consequences of behaviors, thus creating a disconnect between archaeological data and the goal of archaeological research - understanding variation in human behavior. To overcome this limitation, archaeologists use proxies to estimate the types of circumstances people lived in and correlate these proxies with variation in the archaeological record. Strict correlation studies in archaeology are plagued by two significant issues. With the advancement of analytical methods and refinement of data, archaeology has become a big data scientific pursuit, however, without a general theory of human behavior, archaeologists are ill-equipped for discerning causes from correlation and equifinality. Both of these issues can be mitigated with the use of theories, like Cultural Transmission Theory (CTT) and Behavioral Ecology (BE). However, alone, the domain-specific interests of these theories limit their application to a narrow band of explanation. CTT holds that genetics, culture, and the natural environment influence human behavior, and that both culturally and genetically inherited information is acted upon by evolutionary forces and structures human behavior. BE generally explains behavioral variation as adaptive responses to variation in the environment and is agnostic about the mechanisms involved (i.e., genetic, cultural). BE concludes that the behavioral diversity observed in humans is a direct result of the diversity in contemporary socioecological environments. BE and CTT are often juxtaposed, but there is an opportunity to synthesize the two into a pluralistic discipline focused on the evolutionary study of human behavior. Here, we discuss our vision of the complementarity between CTT and BE to facilitate discussion and advance archaeological theory by pursuing their synthezation.

2 USING EVOLUTIONARY THEORY TO UNDERSTAND DIETARY CHANGES IN THE MIDDLE AND UPPER PALEOLITHIC AT HOHLE FELS (SWABIAN JURA, GERMANY)

Starkovich, Britt (SHEP Tübingen) - Münzel, Susanne (University of Tübingen) - Blanco-Lapaz, Angel (SHEP Tübingen) - Conard, Nicholas (University of Tübingen)

Hohle Fels, in the Swabian Jura of Southern Germany, preserves an unparalleled record of Middle and Upper Paleolithic behavior. In over a century of excavations, archaeologists have uncovered large numbers of faunal and lithic remains, as well as some of the oldest Paleolithic figurines, musical instruments, and personal ornaments that date to the Aurignacian. Detailed excavations have also yielded ample microfaunal remains, which have allowed analysts to reconstruct environmental conditions when the site was occupied by Neanderthal and modern human populations. In this paper, we examine hominin subsistence strategies at Hohle Fels diachronically, from the Middle Paleolithic through Magdalenian, drawing on models from human behavioral ecology to do so. We will examine changes in prey choice; animals available in the ecosystem included megafauna (woolly mammoth and rhinoceros), ungulates (reindeer, wild horse, ibex, chamois, red deer, roe deer, and wild pig), small game (hares, birds, and fish), and occasional carnivores (cave bear, cave lion, cave hyena, fox, lynx, and wild cat). We will interpret the data within the context of local paleoenvironmental records, in order to determine if prey choice was more closely linked with environmental conditions, hominin demography, or changing technological solutions. Given the extensive evidence for symbolic expression in the Upper Paleolithic layers of the site, we will also address the explanatory power of Cultural Transmission Theory to help us interpret the faunal record at Hohle Fels.

3 STATISTICAL SIGNALS OF COPYING ARE ROBUST TO TIME- AND SPACE-AVERAGING

Youngblood, Mason (Institute for Advanced Computational Science, Stony Brook University) - Miton, Helena (Stanford University) - Morin, Olivier (Institut Jean Nicod)

Cattle brands (ownership marks left on animals) are subject to forces influencing other graphic codes: the copying of constituent parts, pressure for distinctiveness and pressure for complexity. The historical record of cattle brands in some US states is complete owing to legal registration, providing a unique opportunity to assess how sampling processes leading to time- and space-averaging influence our ability to make inferences from limited datasets in fields like archaeology. In this preregistered study, we used a dataset of ~81,000 Kansas cattle brands (1990–2016) to explore two aspects: (1) the relative influence of copying, pressure for distinctiveness and pressure for complexity on the creation and diffusion of brand components; and (2) the effects of time- and space-averaging on statistical signals. By conducting generative inference with an agent-based model, we found that the patterns in our data are consistent with copying and pressure for intermediate complexity. In addition, by comparing mixed and structured datasets, we found that these statistical signals of copying are robust to, and possibly boosted by, time- and space-averaging.

4 LEVERAGING GENE-CULTURE COPHYLOGENETICS AND THE COMPARATIVE METHOD TO ARTICULATE CULTURAL TRANSMISSION THEORY AND BEHAVIOURAL ECOLOGY

Riede, Felix (Department of Archaeology and Heritage Studies Aarhus University)

I assert that the foundational premises of both Cultural Transmission Theory (CET) and Behavioural Ecology (BE) are correct per se yet each is challenged, in different ways, by the low granularity and large temporal scales of the archaeological record. By usually not accounting explicitly for the historical relatedness of the units under study nor the genetic outcomes of the behaviours in question, BE studies run the risk of statistical invalidity and of telling just-so-stories that assume rather than demonstrate adaptation. In contrast, studies that focus exclusively on cultural transmission dynamics often fail to convincingly explain why the inferred behaviours change over time, ultimately offering similarly unsatisfying accounts. Noting that phylogenetics appears to have waned somewhat in popularity among archaeologists, I here suggest that an expanded and ambitious three-step phylogenetic methodology may in fact offer a rejoinder of CET and BE. In this approach, artefacts, their shapes, and traits are used to infer explicit quantitative hypotheses of historical relatedness among the units in questions. The objects targeted must be sampled in close contextual association (e.g. same grave, same site) with palaeogenetic data such that cophylogenies tracking cultural and biological transmission in parallel may be constructed. Once these are in place, data reflecting the behaviours of the sampled individuals can be added and their statistical association across spatial, climatic, or environmental variables be tested. In doing so, the underlying phylogenetic structure can be used to account for historical relatedness and hence for infamous Galton's Problem. The approach sketched out here is empirically and analytically demanding but is, thanks to recent developments across relevant fields, within reach.

5 MODELING ADVERSITY AND INNOVATION IN THE ARCHAEOLOGICAL RECORD

Herzog, Nicole (University of Denver) - Demps, Kathryn (Boise State University)

Thinking is costly. Nonetheless, humans develop novel solutions to problems and share that knowledge prosocially. We propose that adversity, not prosperity, created a dependence on innovation in our ancestors who were forced through a fitness valley to develop new behaviors and life history characteristics. Using predictions derived from optimal foraging theory, we outline an evolutionary scenario in which a species pushed to the edge is required to develop a new skill-set to survive. We suggest that a fulcrum point in human history hinged on our response to an increasingly variable climate and the spread of open, arid habitats in the Pleistocene. Unable to reduce search costs, our ancestors would have resorted to reducing handling costs to increase foraging returns. At this time individuals must have adopted a new diet, perhaps dominated by underground storage organs. We hypothesize that this shift to higher quality, extractive, and variable food sources led to additional challenges and changes for our lineage, requiring a dependence on exchange, learning, and cooperation.

6 THE NETWORK ECOLOGY OF SETTLEMENT PERSISTENCE

Vernon, Kenneth (University of Colorado) - Ortman, Scott (University of Colorado)

Recent studies of persistence in ancient populations are concerned with the persistence of states and paradigmatic urban concentrations like towns and cities. This ignores settlement persistence at scales that preceded those larger concentrations and, importantly, lacked the highly centralized institutions that could impose meaningful constraints on individual behavior. To fill this lacuna, we draw on ideas and methods from the growing field of network ecology – basically, network science plus population ecology – to evaluate the degree to which social and environmental factors contribute to the persistence of human settlements. Specifically, we focus on dispersed settlements within small-scale agricultural systems that evolved over several hundred years in three regions of the US Southwest: the central Mesa Verde region of southwest Colorado, the northern Rio Grande in New Mexico, and the Zuni or Cibola region on the border between Arizona and New Mexico. Social interaction is measured using weighted network centrality scores derived from commute time estimates between settlements. Environmental data are provided by the Synthesizing Knowledge of Past Environments (SKOPE) project and include climate variables relevant to maize farming, notably temperature and precipitation. To model longevity, we use a Bayesian discrete time proportional hazards model fit with Integrated Nested Laplace Approximation (INLA). By integrating a spatio-temporal covariance structure into this model, we should be able to investigate the contribution made by information exchange – broadly construed – to settlement longevity, all while controlling for the socio-ecological context.

7 'CONCEPTS' IN DYNAMIC ASSEMBLAGES: AN INTEGRATIVE EVOLUTIONARY FRAMEWORK AND ITS APPLICATION TO ARCHAEOLOGICAL QUESTIONS

French, Jennifer (University of Liverpool) - Kissel, Marc (Appalachian State University) - Khaksar, Somaye (Appalachian State University) - Fuentes, Agustín (Princeton University)

Humans are biocultural beings (Fuentes 2023). Both the cultural and biological are central to understanding human behaviour, and crucially, should not be separated within theoretical evolutionary frameworks. In this presentation, we outline a developing body of theory for an integrative approach to cultural evolution deriving from a multi-national interdisciplinary working group of anthropologists, archaeologists and philosophers. This theory is centered on the role of 'concepts' (defined as a suite of articulated and co-ordinated thoughts, ideas, and symbols that structure relationships between individuals and between individuals and their environment) in processes of cultural transmission and change; a role driven by the engagement between 'concepts' and a 'dynamic assemblage' of multiple forces (biology, material objects, environmental and social factors) that afford and constrain biocultural evolutionary trajectories. We consider how this framework relates to, and complements, the evolutionary theories dominant within archaeological research (Behavioural Ecology and Dual Inheritance Theory) and highlight some of the ongoing challenges in identifying both the relevant cultural 'concepts' and the associated 'dynamic assemblage' in archaeological contexts.

8 SOCIO-ENVIRONMENTAL DRIVERS OF PEACE OVER 7,000 YEARS OF ANDEAN DEEP HISTORY: IMPLICATIONS FOR BEHAVIORAL ECOLOGY AND CULTURAL TRANSMISSION THEORIES

McCool, Weston (Department of Anthropology, University of Utah; Society, Water, and Climate Research Group, University of Utah) - Wilson, Kurt (Department of Geography, University of Utah) - Codding, Brian (Department of Anthropology, University of Utah)

As modern anthropogenic climate change threatens to destabilize global societies and ecosystems, studies are needed to anticipate likely human responses. A key global initiative and United Nations Sustainable Development Goal (SDG) is the promotion of peaceful interactions and institutions within an ever changing climate. Archaeology can aid in this pursuit by evaluating dynamic relationships between long-term socio-environmental conditions and peaceful interactions. Nonetheless, studies that theorize what conditions should promote peace and systematically quantify and evaluate driving forces are limited, and research focuses on the last few centuries when climatic conditions were relatively stable. Here, we couple behavioral ecological theory and machine learning models with a cross-regional dataset tracking levels of peace and violence over 7,000 years of Central Andes history to investigate the relative effects of changing climatological, demographic, and socio-political conditions on the degree and duration of peace. We present modeled results and discuss their implications for debates on behavioral ecological and cultural transmission theories of human peace and violence.

9 CONVERGENCE: A LINK BETWEEN BEHAVIOURAL ECOLOGY AND CULTURAL TRANSMISSION THEORY

Rivers, Ray (Imperial College London) - Diachenko, Aleksandr (National Academy of Sciences of Ukraine, Institute of Archaeology, Kyiv) - Sobkowiak-Tabaka, Iwona (Adam Mickiewicz University in Poznań, Faculty of Archaeology,)

The evolution of similar cultural traits can proceed in alternative ways: "homology" and "convergence. Homology presumes a common "ancestor" in traits. Convergence allows for the evolving of artefacts that are similar in form and/or function, but not related to a common "ancestor". While convergence and cultural or demic diffusion alone are rare, growing empirical evidence for convergent evolution permits new theoretical and methodological applications to its analysis which provide important lessons for understanding human behavioural patterns.

As a step towards the synthesis of behavioural ecology and cultural transmission theory, our paper discusses convergence as providing a link between these two theories. We propose quantitative measures that help to understand connectivity and selection reducing variability to variation in long-term cultural trajectories. We begin with a simple example of artificially created and developed technologies, and then extend our approach [1] to a wider set of socio-cultural behavioural patterns evolving at different spatial and chronological scales.

10 ECOLOGICAL AND CULTURAL TRANSMISSION PROCESSES IN LITHIC TECHNOLOGICAL EVOLUTION

Prentiss, Anna (University of Montana) - Walsh, Matthew (National Museum of Denmark) - Denis, Megan (University of Montana) - Foor, Thomas (University of Montana)

Models derived from Behavioral Ecology provide insight into the economic logic behind a wide range of human behaviors. Technological decisions are of interest to archaeologists where investment in lithic reduction and use strategies has received substantial attention. While simple cost-benefit models explain immediate economic contingencies, many scholars point to the likely impact of more complex cultural transmission scenarios. Boyd and Richerson argue that Nomic groups of the North American Great Basin had advantage against neighboring groups given their unique technological repertoire but also their gendered labor and reproduction strategies. Rosenberg is even more explicit suggesting that any form of cultural evolution will be the result of a complex system of hierarchical interrelationships between evolving genealogical and ecological entities. In this paper, we ask if technological evolution is driven singularly by behavioral flexibility associated with ecological conditions or if more complex cultural transmission processes played a more significant role. To accomplish this, we engage in phylogenetic modeling using a data set of 159 lithic assemblages deriving from archaeological sites spanning the Middle Upper Paleolithic of Siberia to the Late Holocene of Northwestern North America. Outcomes of the study provides insights into interaction between economic decision-making and the cultural transmission process.

11 FROM MIND TO MATTER: PATTERNS OF INNOVATION IN THE ARCHAEOLOGICAL RECORD AND THE ECOLOGY OF SOCIAL LEARNING

Demps, Kathryn (Boise State University) - Herzog, Nicole (Denver University) - Clark, Matt (Imperial College London)

We use the case study of the adoption of the bow and arrow in the Great Basin to infer how patterns of cultural variation, invention, and innovation affect investment in new technologies over time and the conditions under which we could predict cultural innovation to occur. Using an agent-based simulation to investigate the conditions that manifest in the innovation of technology, we find the following: (1) increasing ecological variation results in a greater reliance on individual learning, even when this decreases average fitness due to the costs of learning; (2) decreasing population size increases variability in the types of learning strategies that individuals use; among smaller populations drift-like processes may contribute to randomization in interpopulation cultural diffusion; (3) increasing the mutation rate affects the variability in learning patterns at different rates of environmental variation; and (4) increasing selection pressure increases the reliance on social learning. We encourage others to use our open-source R code to test their own hypotheses and discuss with us: <https://github.com/matthewclark1223/MindToMatter>

12 TESTING HYPOTHESES OF CULTURAL HITCH-HIKING IN PREHISTORY

Shennan, Stephen (University College London) - Kolar, Jan (University College London) - Lee, Victor Yan Kin (University of Copenhagen) - Racimo, Fernando (University of Copenhagen) - Staniuk, Robert (University College London) - Thomas, Mark G. (University College London) - Timpson, Adrian (University College London)

Many if not most of the cultural traits that archaeologists describe and record have no obvious biological selective value but may simply be neutral, in that their changing frequencies are governed by random sampling processes in cultural transmission together with occasional innovations. Testing hypotheses of neutrality versus alternatives, such as copying the locally most common, most prestigious, or most functionally successful variants of any given cultural feature may be relatively straightforward in cases where the underlying population is in equilibrium. However, as we now know, local populations fluctuated in size and often received inputs from neighbouring regions. In this paper we will use available data from Western Eurasia on demographic patterns and ancient gene flow to evaluate the extent to which cultural trait frequencies simply hitch-hiked on underlying demographic processes. To do so we will use data being collected by the ERC-funded COREX project, linked together in the BIAD archaeological database and connected to ancient DNA data.

13 COMPETING OR COMPLEMENTARY? THE ROLE OF EVOLUTIONARY ECOLOGY AND CULTURAL TRANSMISSION THEORY IN EXPLAINING TECHNOLOGICAL COMPLEXITY

Codding, Brian (University of Utah) - Brewer, Simon (University of Utah)

Evolutionary ecology and cultural transmission theory offer different perspectives to assess patterning in material culture complexity. Sometimes these theories offer competing hypotheses, such as the causal pathways linking demography and technological innovation. Other times they operate at different levels of explanation that may be complementary, such as examining the adaptive function vs cultural phylogeny of specific technologies. Here we examine both the competing and complementary roles of evolutionary ecology and cultural transmission theory in

accounting for variation in technological complexity. First we assess model expectations from each framework using cross-cultural data on forager and farmer societies across western North America. We then leverage these results to help evaluate the possible drivers of technological change in the archaeological record across foraging and farming populations in western North America and western Europe. The results help explain patterning in material culture complexity across past human societies and provide an opportunity to advance a comprehensive framework for understanding technological change.

1048 ANTIQUES, HEIRLOOMS, AND MEMORABILIA: THE RELATIONSHIP BETWEEN PORTABLE OBJECTS AND MEMORY IN THE ANCIENT WORLD

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Ward, Courtney (independent scholar) - Barrero Martin, Nova (National Museum of Roman Art, Mérida)

Session format: Regular session

Portable objects and small finds constitute a large and important body of evidence from the ancient world. While portable personal possessions could be retained over significant periods for economic reasons, this explanation does not address all instances. By their nature, these smaller objects could easily change hands (e.g., sold to new owners or passed down from one family member to another). The focus of this session is on the meeting of material and memory. In particular, it will look at the identification and interpretation of valued personal possessions (e.g., adornment, tableware, souvenirs) – that is objects that were worn, used, and above all, retained due to their connection with specific individuals or events.

Antiques, heirlooms, and memorabilia were all tied to memories – of earlier periods, past owners, or particular events. They were valued, respectively, for their age or the fame of their maker, for the connection to the people from whom they were received, and for their association with specific places or events. The session seeks papers focused on how these objects can be identified in the archaeological record (wear patterns, signs of repair, anachronistic styles, specific motifs, etc.), what this can tell us about their role in linking different generations or specific communities, and the value that material culture held beyond economics.

Potential topics include:

What do we know about the market for memorabilia and souvenirs in the ancient world and how it relates to ideas of memory?

What do literary and epigraphic sources reveal about the passing of objects between individuals and the importance of personal connections?

While some objects were made explicitly for the purpose (e.g., the fourth/fifth-century AD Sevso plate), how did other objects become heirlooms?

How can we address the changing meaning of objects as they changed hands?

ABSTRACTS

1 PORTABLE MONUMENTA: OBJECT BIOGRAPHIES AND COLLECTING PRACTICES IN ROMAN IMPERIAL TIMES

Colzani, Giovanni (Università degli Studi di Milano)

Greek and Roman authors offer several anecdotes about heirlooms and revered artifacts, eagerly pursued by collectors and highly valued in the marketplace for their association with prominent figures from ancient history: from Philip II's silver service (Iuv. 12, 46-47) to the diamond gifted by Agrippa II to the princess Berenice (Iuv. 6, 156-158), including seemingly humbler objects such as Epictetus's terracotta lamp and Peregrinus Proteus' staff (Luc. Adv. Ind., 13). Caracalla boasted of possessing the weapons of Alexander the Great (Cass. Dio. 77, 7), while Zenobia, in a similar form of imitatio, displayed at her banquets the golden vessels once belonging to Cleopatra (Hist. Aug., Treb., 24, 30, 19). Caligula put up for sale several jewels from the imperial treasury, insisting that they be valued higher due to their previous ownership by Germanicus, Agrippina, Mark Antony, and Augustus (Suet. Cal. 39), while the connoisseur Novius Vindex proudly showcased in his collection a bronze statuette that had passed into the hands of Alexander the Great, Hannibal and Sulla (Stat. Silv. 4, 6, 45; Mart. 9, 43-44). Regardless of the merits of such claims, the insistence on this 'associative value' underscores the cultural role attributed to these objects, imbued with symbolic significance and the capacity to serve as 'portable monuments' (monumenta) of a particular era, its major personalities, and its ideology. Their status is not related simply (or at all!) to the artistic excellence or the skill of their makers, but rather to the fame of their former owners and patrons, capable of bestowing upon them an enhanced dignitas. The

construction of elaborate biographies and distinguished pedigrees thus becomes a recurring theme in the description of these memorabilia, sometimes attracting the irony of the most disenchanting observers (Mart. 8, 6).

2 MIRROR MIRROR: REFLECTING ELITE LEGACY IN ANCIENT POMPEIAN HOUSES

Murphy, Mamie (John Cabot University)

This study analyzes the four precious mirror-like obsidian panels embedded into the peristyle and atrium walls of the House of the Golden Cupids, the House of the Fruit Orchard, and the House of the Ephebe in ancient Roman Pompeii (1st century CE). While these obsidian mirrors were undoubtedly prized for their rarity and economic value, this study proposes a greater purpose behind their purchase and retention: the obsidian mirrors were intended to leave lasting impressions on guests during the *cena*—a ritual deeply intertwined with bolstering the host's social status. The obsidian mirrors achieve this through obsidian's ability to foster a liminal environment that directly inserts viewers into the decorative programs of their houses to entertain and impress their owners' guests.

Therefore, this paper examines the obsidian mirrors as treasured heirlooms intimately linked to the personal identities of the mirrors' owners and their families, as well as to the event of the *cena*. This will be realized through an investigation of the obsidian mirrors' production and importation process, potential post-earthquake refurbishment (62 CE), and their integral role as active agents within their owners' highly individualized domestic decorative programs.

Given the obsidian mirrors' physical connection to their respective houses and key role in facilitating their residences' immersive entertainment system—both of which were inextricably intertwined with the family who owned the house—this paper suggests the obsidian mirrors' owners likely treasured the mirrors as prized belongings to be cared for by the generations of family members occupying these houses. Ergo, the obsidian mirrors embody the convergence of materiality and memory, serving not merely as symbols of luxury but also as enduring emblems of personal legacy.

3 PORTABLE SHRINES IN THE ANCIENT WORLD: BETWEEN MEMORABILIA AND PRIVATE CULT. THE CASE OF THE VALLE PONTI MINIATURE LEAD TEMPLES

Regueiro Salcedo, Ian (University of Ferrara)

The six lead miniature temples found inside the shipwreck of Valle Ponti, located at Comacchio (province of Ferrara, Italy) and dated to the last quarter of the first century BC, have often been interpreted as a unicum in the Roman world. Some authors have seen in them an archaeological evocation of the Ephesian silver shrines mentioned in the Act of the Apostles: A silversmith called Demetrius and other artisans were engaged in crafting miniature silver versions of the Ephesian temple to Artemis for sale to visitors. The temples from Comacchio, indeed, have until now been interpreted as simulacra of real standing temples, and their presence in the shipwreck limited to economic reasons, being considered part of the selling cargo. The main objective of this study is the contextualization of these miniature portable shrines within the ancient world. Through the written sources and the iconographic and archaeological comparisons with similar miniatures new interpretative perspectives have been opened on the reasons behind the production of the lead temples, their use and the scope for which they may have been crafted. Some symbolic elements and the deities represented in the Valle Ponti temples seem to provide important clues about the ritual and religiosity on the wreck. At the same time, other portable lead shrines with similar functional elements found along the Roman provinces could talk about a class of dynamic objects within the private sphere, related to mobility and used for multiple purposes. From funerary to military contexts, the so-called Portable Shrines could offer new perspectives on the relation between individuals and miniature objects.

4 TRADITION MEETS CONVENIENCE: CULT INSTRUMENTS AS MEMORABILIA

Zepernick, Marte (Philipps-Universität Marburg)

Cult instruments played an active part in ancient cult practice. However, their role as significant objects per se — intertwined in traditions marked by religious habits as well as various people interacting with such objects across generations — has rarely been explored. Concerning ancient Greek cult instruments, literary sources reveal that such objects could be of personal value. For instance, Achilles' libation before Patroclus rejoins the battle against the Trojans in the Iliad is framed by highlighting the libation cup's divine origin, as a precious, well-stored present given by Achilles' mother. Also, deposition practices underline that cult instruments were embedded in Greek memory culture, as dedicated testimonies of former cult practice. But, in how far did this relationship between religious objects and different members of the cult community vary and relate to the past? The paper explores ancient Greek cult instruments as memorabilia with a focus on literary and epigraphic evidence. It analyses the connotation attached to cult instruments as agents in Greek cult bridging generations, by addressing their double role as necessary tools for rituals and relicts. Thus, it contributes to connecting the materiality of religion and memory culture.

5 THE MEMORY OBJECT CONNECTIONS AND TRANSMISSIBILITY OF IMAGINES MAIORUM

McCahill, Mark (Independent scholar)

This paper will provide a rationale for considering more substantial sculptural veristic images as *imagines maiorum* (embodied ancestors), rather than the limiting ancient variant of an ancestor mask rendered in wax: it is not extant as a primary source, except second-hand through ancient writers attesting to existence and their significance as memory objects.

This extension of scope supports a switch away from the limited nature of the frangible contemporaneous objects missing from the archaeological record, whilst providing suitable provenance through that extant written primary source material that also utilises *ἐνάργεια* (an ancient Greek term meaning vividness) to help pictorialize sculptural ancestral images and their transmissibility as historical exemplars.

Memorialisation and ancestral legacy imagery in, for example, the frieze depictions from the Ara Pacis Augustae (Altar of Augustan Peace), challenge the privileging of the wax mask variant and emphasise more substantive forms — like reliefs and marble busts — as better narrators of family inheritance and memory, confirming an enduring legacy across a longer timeframe than frangible ancestor masks.

As a specific monument, the Ara Pacis would then allow the expanding imperial family to exploit the built environment narrative using this monument and others — like the Forum Augustae and its aetiological layout of prominent ancestors and their exemplary *romanitas* (Roman-ness) and *virtus* (virtue) — as they used these enduring sculptural objects to link generations via emulation, memory generation, and exemplary Roman representation.

6 A LITERARY PERSPECTIVE ON PORTABLE OBJECTS: THE CULTURAL CACHET OF SPOILS, SOUVENIRS, AND HEIRLOOMS IN LATE REPUBLICAN ROME

Baarda, Tom (University of Cambridge)

The 'value' of objects in late republican Rome went far beyond simple economics, and instead was a central part of the 'economics of status' (Jehne 2016) contested as much in the dining room as in the senate house. Portable objects were tangible expressions of the cultural capital derived from the different networks that bestowed power: aristocratic dynasties (heirlooms) and the expanding empire (spoils and imports). Catullus, who wrote poetry in Rome in the mid-50s BC, has long been seen as an important source for the 'language of social performance' (Krostenko 2001) by which elite behaviour was evaluated. He was also a junior officer in the retinue of a provincial governor, and his poems are full of objects passed between him and his friends. In Poems 12 and 25, the theft of a napkin reveals the different sources of the object's value: explicitly not its economic worth (*aestimatio*), but its role in facilitating the social exchange of the elite dinner party (*convivium*). In particular, this 'memento' embodies Catullus' relationship with the absent friend who sent it: we see an explicit thematization of the role of the 'souvenir' (*mnemosynum*) in creating memory. The napkin's association with its origin in Saetabis, Spain (a centre of textile manufacture) reveals the cultural cachet that Romans attached to imperial provenance ('cargo chic'). We also see the changing meaning of the napkin in the hands of its owner (Catullus) and the thieves with different social status, through an interaction with another category of object with a particular social capital: heirlooms (*avita*). The interaction of two distinct categories of portable object currently provoking scholarly interest — souvenirs (Cassibry 2021; Popkin 2022) and spoils (Helm and Roselaar 2023; de Jong and Versluys 2024) — are revealed through this literary perspective from the particular 'imperial moment' of late republican Rome.

7 REPAIR PRACTICES AS A MEMORY STRATEGY IN ANCIENT GREECE?

Lindenlauf, Astrid (Bryn Mawr College)

Objects fall apart and break at different rates, but they tend to reach their use life eventually. When this happens, they get thrown away, moved into special storage spaces, or repaired. This paper focuses on repair jobs carried out in ancient Greece to determine under which circumstances artifacts were considered worth repairing. It also investigates changes in affordances, functionalities, and uses of repaired artifacts. Greek repair practices tend to be explained in terms of economic necessities, but this functionalist approach disregards the personal experiences that tie people to their artifacts. I suggest that the willingness to spend time, material or money on extensive repair jobs that do not restore an item's full working condition may be indicative of an emotional attachment to the restored object, transforming it to a memento. To gain a better understanding of this phenomenon in ancient Greece, sympotic pottery associated with the prestigious social institution of the symposium is compared and contrasted with cooking ware with respect to the frequencies of repair, the scale and execution of repair, and the change in function and meaning of vessels.

HOARDING HEIRLOOMS

Davis, Mary (National Museums Scotland) - Goldberg, Martin (National Museums Scotland)

The 'Viking-age' Galloway Hoard from south-west Scotland contains Hiberno-Scandinavian material which in many ways epitomises the bullion nature of such hoards in the Irish Sea zone around AD 900. However, buried alongside silver arm rings and ingots was an elaborate silver gilt lidded vessel packed full of objects of a very different character. Many of these were several hundred years old, made of glass, stone and even dirt. Some were wrapped in textiles and placed together with other personal valuables such as contemporary brooches, gold mounts, silk braids and an unusual rock crystal jar – with the name of a Northumbrian bishop inscribed in gold on its base. A number of these objects were probably of religious value and significance, while others might have represented objects passed down through family lines. Several items are most closely paralleled in Merovingian and pagan Anglo Saxon female graves, introducing aspects relevant to the female guardianship and inheritance of material culture in the early Medieval period.

This collection of jewellery, amulets, relics and heirlooms presents a unique opportunity to look at different 'values' through distant connections in terms of both time and place and consider the juxtaposition of culturally distinct materials connected through burial together in a complex hoard.

1049 TIL DEATH DO US PART. REVISITING THE QUESTION OF DOUBLE BURIALS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Büster, Lindsey (University of York; Canterbury Christ Church University) - Knüsel, Christopher (UMR 5199, PACEA, Université de Bordeaux)

Session format: Regular session

Double burials (co-buried individuals in the same grave feature) are well attested in the archaeological record and have been interpreted in numerous ways: the 'mother and child' from Mesolithic Vedbæk (Denmark), the 'murdered' Mesolithic 'Ladies of Téviec' (Brittany, France), or the inferred social acceptance of the early medieval 'same-sex couple' buried in Grave 96, at Buckland (Dover, Kent, UK). While archaeologists have recognised the inherent ethno-centric and androcentric biases they bring to interpretations of the burial record and have embraced new theoretical frameworks for understanding personhood and identity, this seems not to have been extended frequently or uniformly to co-burials.

Recent methodological advances, such as genome-wide analysis of ancient DNA and the increased application of archaeoethanatomical principles, are beginning to shed light on the diverse composition of such burials, even in cases where mortuary tableaux superficially suggest rapid and 'conventional' deposition. Examination by the COMMIOS Project (<https://commiosarchaeology.com/>) of the co-burial of a 24-year-old man and his >45-year-old daughter at the Iron Age site of Wattle Syke (West Yorkshire, UK) highlights the complex and protracted nature of engagements with the dead which might have been otherwise overlooked. Even in the absence of aDNA analysis, a combined historical and bioarchaeological study of the 'St. Bees Lady', a female buried next to the exceptionally well-preserved late medieval 'Saint Bees Man', suggests a brother and his sister.

This session invites papers which apply new and current techniques, methodologies and frameworks to co-buried individuals, to shed light on complex kinship systems, protracted death rituals and, at times, simultaneous deaths. Papers considering burials of more than two individuals, including internal relationships in mass and collective graves, are also encouraged.

ABSTRACTS

1 ANCIENT GENOMES OF ÇATALHÖYÜK REVEAL DIACHRONIC CHANGES IN FUNERARY PRACTICES AND HOUSE USE

Yüncü, Eren (Middle East Technical University) - Küçükakdağ Doğu, Ayça (Middle East Technical University) - Kaptan, Damla (Middle East Technical University) - Mazzucato, Camilla (University of Copenhagen) - Pearson, Jessica (University of Liverpool) - Güler, Merve Nur (Middle East Technical University) - Eker, Elifnaz (Middle East Technical University) - 2014-2017, Çatalhöyük Human Remains Team (University of Bordeaux) - 2014-2017, Çatalhöyük Excavation Team (University of Stanford) - Ancient DNA Team, METU/Hacettepe (Middle East Technical University)

This investigation documents and interprets population structure and the long-standing question of intramural biological relatedness at Neolithic Çatalhöyük, Turkey (7100-5950 BCE) using an archaeogenomic dataset of 132 individuals spanning the Early (7100-6700 BCE), Middle (6700-6500 BCE) and Late (6500-6300 BCE) periods. Our results reveal that through its occupation the village gene pool did not change significantly. We also do not detect the presence of any individuals with significantly different genetic backgrounds, suggesting limited, if any, immigration

into the site from distant regions (e.g. the Levant, Zagros, or the Aegean). We next investigated genetic kinship among intramural burials in 23 buildings on an archaeogenomic sample 3/4 comprised of subadults. During the Early-level occupation, we find that individuals were often buried in the same building with at least one close relative, a pattern similar to that previously reported for Pre-Pottery Neolithic sites in Anatolia. The frequency of close genetic kinship among such co-burials declined in Middle-level buildings, with children from multiple biological families being buried in the same house. The frequency of co-burial genetic kinship decreased even further in the Late period-level buildings. A Monte Carlo simulation test shows that these temporal changes cannot be attributed to differences in sample sizes or bias in genetic sampling. We discuss possible explanations for the apparent change in the frequencies of close genetic relatedness among individuals across the occupation of Çatalhöyük.

2 CO-BURIAL IN NEOLITHIC ANATOLIA: AN EXPLORATION OF MEANING AND PURPOSE

Pilloud, Marin (University of Nevada, Reno)

The Neolithic archaeological sites of Central Anatolia are well-known for their intramural burials. In the case of Çatalhöyük, individuals were buried at the same time, whereas, in other instances, the same burial location was visited multiple times to inter additional individuals. The meaning of this co-burial has been variably interpreted to be indicative of co-habitating biological kin or as collectives of 'practical kin'; however, no clear patterns have emerged to definitively answer why individuals were interred together and others were not. Similar practices of intramural burial are found in other Anatolian Neolithic sites. This paper serves to re-evaluate the meaning of this mortuary practice through emerging methods exploring biological distance analysis.

Dental morphometric data were explored from several Neolithic Anatolian sites that span the early aceramic to the later Pottery Neolithic (Boncuklu, Aşıklı Höyük, Çatalhöyük, and Barcın Höyük). To understand social structure, biological relationships within interments were explored. The data reveal that biological relationships were more frequent between individuals buried within the same building early in the Neolithic, but, over time, such relationships appear to become less important, as the number of biologically related co-burials decreases. Variation in phenotypic data between sites and males and females was explored to understand migration patterns. This research highlights the role of emerging technologies in understanding complex mortuary behavior and the varied ways in which co-burials can be interpreted.

3 ANCIENT DNA IN CO-BURIED REMAINS FROM THE NEOLITHIC AND ENEOLITHIC NORTH PONTIC REGION SHEDS LIGHT ON ANCIENT BURIAL PRACTICES

Svyryd, Sofiia (Grand Valley State University) - Nikitin, Alexey (Grand Valley State University)

Ancient DNA studies have revealed a complex pattern of relationships among individuals interred in the same grave across ancient Europe. This presentation will discuss burial connections in the prehistoric steppe and forest-steppe north of the Black Sea (the North Pontic Region). In the Neolithic period (6200-5000 BCE) in the North Pontic steppe, we observe first- and second-degree relatives variously distributed within collective graves and in single burials at Mariupol type cemeteries of the Neolithic hunter-fishers in southeast Ukraine situated along the Dnipro Valley. Conversely, at a collective burial site of Trypillia archaeological culture complex in the North Pontic forest-steppe dating to the Eneolithic period (5000-3300 BCE), no detectable kinship is observed among the remains. In the Eneolithic steppe, relationships vary from no detectable relatedness to first-degree kinship among co-buried individuals of various steppe archaeological groups. At the same time, second-degree kinship has been identified in contemporaneous steppe burials situated two thousand kilometers apart.

4 MIXED FUNERARY PRACTICES AND CREATIVE RELATIONS WITH THE DEAD: BELL-BEAKER CO-BURIALS FROM NOGAROLE ROCCA (VERONA), ITALY

Thompson, Jess (University of Cambridge) - Salzani, Paola (Soprintendenza Archeologia, Belle Arti e Paesaggio di Verona, Rovigo e Vicenza) - Panella, Sofia (Department of Environmental Biology and Mediterranean bioArchaeological Research Advances (MAREA) Centre, Sapienza University of Rome) - Soncin, Silvia (Department of Environmental Biology and Mediterranean bioArchaeological Research Advances (MAREA) Centre, Sapienza University of Rome) - Saupe, Tina (Uppsala University) - Dori, Irene (University of Florence) - Tafuri, Mary Anne (Department of Environmental Biology and Mediterranean bioArchaeological Research Advances (MAREA) Centre, Sapienza University of Rome) - Robb, John (University of Cambridge)

Co-burials and double burials have typically been assumed to hold close kin or partners, (re)united in death. Such ideas are now testable and genetic estimation of relatedness is revealing local differences in the kinds of kin that were drawn together in death. But how do we assess burials containing multiple individuals when the funerary practices were also multiple and mixed?

We address this problem through a close analysis of bell beaker period burials from the Nogarole Rocca necropolis, Verona. Dating between 2540-2305 cal BCE (95.4%), 8 graves attested to the concurrent practices of inhumation

tion, cremation and secondary deposition. Three out of 8 of these graves contained multiple individuals in different forms: one grave held the cremated remains of 3 people of different ages, another contained a cremation with part of an unburnt cranium and mandible deposited alongside, and the last held an inhumation which had been disturbed to inter a cremation.

Given the difficulties with aligning the same sets of analyses on burnt and unburnt remains, and the singular and idiosyncratic nature of each of these graves, how do we interpret the relations within and between them? Genomic sequencing of the unburnt cranium and the inhumation in these co-burials shows these two individuals were related to a nonadult who was buried alone, and may also have been related to one another. We discuss different interpretations of these creative funerary practices from the available osteological and biomolecular data, suggesting that diverse modes of kinship and ancestral relations structured the mixed depositions at Nogarole Rocca.

5 A CLOSE EMBRACE: A UNIQUE DOUBLE BURIAL FROM THE EARLY MYCENAEAN AYIOS VASILEIOS NORTH CEMETERY, LACONIA, GREECE

Moutafi, Ioanna (Ludwig-Maximilians-Universität München) - Voutsaki, Sofia (University of Groningen)

Late Bronze Age (1700 – 1100 BCE) funerary practices in the southern Greek mainland include a diverse range of burial disposals, from primary and intact single burials to collective assemblages of multiple interments, whether primary or secondary, intact or disarticulated, simultaneous or successive, few or many. Funerary choices raise questions about personhood, or the construction of social identities and relationships, and are therefore essential for a better understanding of social dynamics. The Early Mycenaean (ca. 1700-1450 BCE) Ayios Vasileios North Cemetery (AVNC) in Laconia, Greece, is of special interest in these enquiries, as it comes into use when novel and diverse funerary practices emerge, including a shift from single to collective burials. Excavated recently and currently undergoing a multi-disciplinary study of all field data, the AVNC provides an ideal opportunity for an accurate reconstruction of the variable mortuary treatment and its underlying meanings.

Notwithstanding the mortuary diversity in the prehistoric Aegean, double burials remain unusual. This is also the case for the AVNC, which includes very few such cases despite large variability in modes of disposal and Minimum Numbers of Individuals (MNI). In this paper, we focus on a most striking double burial, i.e. two skeletons placed contracted in a close embrace position inside a large pit (tomb 17). In terms of grave structure, MNI and body placement, Tomb 17 is a special, unique case in AVNC. Employing a multi-dimensional methodology that integrates archaeoanthatology, taphonomy, osteobiographies, biomolecular analyses and the contextual analysis of the mortuary practices, we try to shed light on the identity of these people, the particular circumstances of their deaths, the motivation and emotions behind their shared burial. Going a step further, we would also like to take into consideration our own response to this unexpected burial and the ethical questions it raises.

6 FAMILY TIES: KINSHIP AND COMPLEXITY IN THE 'DOUBLE BURIALS' OF IRON AGE BRITAIN

Büster, Lindsey (University of York; Canterbury Christ Church University)

Advances in ancient DNA analysis have revolutionised our ability to study the relationship between biological relatedness and socially constructed kin. Using data from the COMMIOS Project and comparanda from the published literature, this paper explores the potential of aDNA evidence to shed light on the phenomenon of co-buried individuals in Iron Age Britain and highlights some of the ways in which ethnocentrism has influenced past interpretations of the social identity of these individuals.

Coupled with osteology, archaeoanthatology and isotopic analysis, not only are these data revealing complex sub-structures of kin identity among the living, but dynamic and often protracted interactions between the living and the dead. Data on biological relatedness and age-at-death has, for example, highlighted the very different mortuary treatments that certain co-buried individuals received, including above-ground curation, exhumation and grave reopening. Such extended mortuary processes suggest that the Iron Age dead (whether physically present or not) would have been an important and enduring part of daily life, tying families (and communities) together across the generations. Recognition of these complex interactions also provides important context for the variety of mortuary treatments across Iron Age Britain, including increasing recognition of curated remains, and the blurring of lines between the sacred and the profane at this time.

Drawing on multiple lines of evidence to lift the lid on these so-called 'closed contexts', this paper invites us to abandon notions that the prehistoric dead were necessarily intended to 'rest in peace', to re-examine the rhythm and tempo of mortuary processes, and to embrace the 'messiness' of Iron Age life and death.

7 ANCIENT GENOMES OF ÇATALHÖYÜK REVEAL NOVEL AGE- AND SEX-SPECIFIC BURIAL TREATMENT PRACTICES

Küçükakdag Dogu, Ayça (Middle East Technical University) - Yüncü, Eren (Middle East Technical University) - Kaptan, Damla (Middle East Technical University) - Haddow, Scott (University of Copenhagen) - Kılıç, Muhammed (Middle East Technical University) - Vasic, Milena (Freie Universität Berlin) - Vural, Kıvılcım (Middle East Technical University) - 2014-2017, Çatalhöyük Human Remains Team (University of Bordeaux) - 2014-2017, Çatalhöyük Excavation Team (Stanford University) - Ancient DNA Team, METU/Hacettepe (Middle East Technical University)

Çatalhöyük East Mound in the Anatolian Konya Plain was settled between 7100 BC and 5950 BC, with continuous occupation for c.50 generations. Although decades of analysis have revealed numerous details of daily life at Çatalhöyük, ancient genome data is providing novel insights into social practices. Here we present results based on shotgun DNA sequencing of skeletal remains from 414 Neolithic-period intramural burials. The data revealed highly variable DNA preservation among individuals, measured as the proportion of endogenous (i.e., human) DNA molecules among all sequenced DNA molecules. Interestingly, we found significantly higher DNA preservation among subadults compared to adults. The absence of similar patterns in published archaeogenomic datasets from other prehistoric sites suggests that this is unlikely to be related to age-biased taphonomic processes. Instead, it likely represents differential burial practices for adults and subadults in Çatalhöyük. These practices may reflect age-specific funerary treatments including the possible effect of different spatial placement of burials within houses, as previously described for this site. Second, we present results on sex differences -in the type and amount of burial-associated objects among subadults. Shells, beads, baskets, bone objects, and blades were found in association with a minority of burials at Çatalhöyük, with a higher association of these items with adults, especially with adult females than with adult males. When zooming in on subadults, our new data highlight a similar pattern between sexes, with females showing a significantly higher frequency of burial-associated objects than males. We also find that female subadult skeletons have a degree of DNA preservation than male subadults; suggesting that female subadults were treated more similar to adults when compared with male subadults. Our results suggest previously unknown differences in funerary treatment at Çatalhöyük between adults and nonadults, and, for the latter, sex-specific burial practices.

8 THE GRAVE'S EMBRACE: BIOLOGICAL AND SOCIAL RELATIONS IN BEAKER PERIOD ADULT-CHILD GRAVES REVEALED BY ANCIENT DNA

Zedda, Nicoletta (Department of Environmental and Prevention Sciences, University of Ferrara, Ferrara, Italy) - Meheux, Katie (Institute of Archaeology Library, LCCOS, University College London, London, UK) - Brami, Maxime (Palaeogenetics Group, Institute of Organismic and Molecular Evolution (iomE), Johannes Gutenberg University Mainz, Mainz, Germany)

In this presentation, we take a closer look at a particular type of double burial known in German literature as 'mother-child burials'. Shared burials of adults and children are remarkably common throughout Europe in the third and second millennia BC, despite a widespread shift from collective to single inhumation. To find out more about the relationships between the co-buried individuals, we sampled two double graves from the Bell Beaker culture in Northwest Europe, Altwies in Luxembourg, and Dunstable Downs in Britain (Zedda, Meheux et al. 2023). The two graves, located over 500 kilometres apart, were strikingly similar, consisting of an adult woman and a small child facing each other in death, accompanied by fossils and remains of a Beaker vessel. Ancient DNA analyses conducted at the Palaeogenetics Laboratory of Johannes Gutenberg University Mainz, with the support of the Institut National de Recherches Archéologiques, Luxembourg, have now provided more information about the co-buried individuals, who were related in both cases. These analyses reveal that children were sometimes buried with their biological parents and other close kins, such as a paternal aunt at Dunstable Downs. A comparative analysis of over 100 published adult-child graves dating to the third and second millennia BC highlights the complexity of this practice, which has often aroused suspicion of violence and/or epidemic diseases. We suggest that the body of a woman, lying as though sleeping, clasping a child in her arms, had a specific meaning to early Bronze Age communities. This aesthetically consistent configuration was potentially more important than the cause of death and even the biological relation between the adult and child.

Zedda, N., Meheux, K., Blöcher, J. et al. Biological and substitute parents in Beaker period adult-child graves. *Sci Rep* 13, 18765 (2023). <https://doi.org/10.1038/s41598-023-45612-3>.

9 REINTERPRETING MULTIPLE BURIALS WITH NON-ADULT INDIVIDUALS: CHILDREN'S AGENCY AND SOCIAL BONDS IN COPPER AND BRONZE AGE IBERIA

Herrero-Corral, Ana (Austrian Archaeological Institute, Austrian Academy of Sciences) - Garrido Pena, Rafael (Universidad Autónoma de Madrid, Spain) - Paulos Bravo, Rodrigo (Universidad Complutense de Madrid, Spain) - Flores Fernández, Raúl (Independent scholar, Madrid, Spain) - Rebay-Salisbury, Katharina (University of Vienna, Austria; Austrian Archaeological Institute, Austrian Academy of Sciences) - Kanz, Fabian (Medical University of Vienna, Austria)

Double or multiple burials of children and adults are often interpreted in two different ways: either as the intentional act of burying a deceased child alongside another close family member (usually a biological parent), or as a practical act of burying a child in any structure of another person who has died close in time. In either of these two interpretations, neither the importance of children is recognized, nor their ability to create social bonds with other group members. The aim of this study is to provide alternative interpretations of multiple burials with children through the case study of the site of Humanejos (Madrid, Spain). In this necropolis, spanning the entire Copper Age and a significant part of the Bronze Age (c. 3000-1500 BCE), a total of 61 non-adult individuals have been analyzed, with over 70% from double or multiple burials. The types of accompanying individuals, the primary or secondary nature of the deposits, the ages at death, and the identification of biological sex through peptide analysis allow for a more comprehensive understanding of the various scenarios these burials may represent. Pending genetic results on biological relatedness, the study of these burials has already yielded new findings on kinship construction, such as the intentional selection of certain children from a specific age and sex group in secondary deposits.

10 POTENT PERFORMANCES: NEW APPROACHES TO INFANT-ADULT DOUBLE BURIALS IN ROMAN BRITAIN

Phillips, Reanna (University of Chester)

While approaches to infant burial in Roman Britain have been greatly updated in recent years, key questions have yet to be addressed. Moving past notions of unceremonious disposal and presumed unimportance in life or in death, infant burial practices in Roman Britain have been shown to be dynamic and varied, with evidence of emotion evoked through selected rites conducted in domestic contexts as well as cemetery landscapes. When infants have been found 'accompanying' burials of adult individuals in urban cemeteries, these burials have often been understudied by investigations of double burial in Roman Britain, seemingly treated as opportunistic 'additions' to the adult burial and not considered 'agents' in these funeral performances.

However, the diversity of evidence and the underrepresentation of infants in the burial record suggests the memorable nature of these infant-adult burial practices and their potent effects on the social memory of living communities. This paper reconsiders a range of infant-adult double burials in Roman Britain, examining evidence of performances and participation throughout the burial process. Double inhumation and cremation grave contexts will be investigated, highlighting the motives and variations in choices made by the living participants across the stages of these burials. The paper will ultimately provide new interpretations and suggest future approaches to these burial rites which can mediate the complex social role of infants, the relationships between the buried dead and between the living participants in funerary performances.

11 CHILDREN IN MULTIPLE BURIALS AS A SOURCE FOR SOCIAL STUDIES (ON EXAMPLES FROM OLD RUS' PERIOD BARROW CEMETERIES IN BELARUS)

Makouskaya, Viktoryia (University of Warsaw)

Children's burials are the illustration of how children were viewed by adult members of the community. Among them, multiple burials stand out - including the graves of several individuals from different age groups, who may have had different social status. The aim of the research undertaken here was to identify various features of children's burials in common barrows from three regions of Belarus: from the Polack land (associated with the area of the historical Polack principality) and from the basin of the Niemen and Bug rivers. A total of 39 barrows with children's burials were analysed, resulting in an attempt to organise this material on the basis of age and the relationship between the buried individuals (various forms of multiple burials of adults and children and only children; cases indicating special treatment of children in the context of the sphere of the sacrum, in which a child's burial appears as a "grave good" of an adult, has a marginal position in the space of the barrow or is a trace of a secondary, i.e. later burial, were also recorded).

The investigated cemeteries are located in the vicinity of Old Russian towns or local administrative centers, and the children's burials recorded in them can be dated to the 11th-12th centuries, i.e. to the period of the rooting and unification of the Christian burial rite in the area. Although barrows with mass graves were not the most common practice there, they accounted for a significant proportion, up to one-third, of the children's burials discovered in the Polack land. Differences in the treatment of children in multiple burials are particularly evident in relation to the graves of

the youngest children (infans I), which can be interpreted as a trace of a certain stage of their adolescence, which was related to their social status.

12 WHY BURY TOGETHER? FUNERARY EXPRESSIONS OF DEATH DURING GESTATION AND CHILDBIRTH IN CATHOLIC AND PROTESTANT POPULATIONS IN 18TH-CENTURY LA ROCHELLE

Souquet, Isabelle (INRAP) - Guillon, Mark (INRAP) - Rousseau, Elisabeth (INRAP)

Burials associating a very young child with an adult are not uncommon in French cemeteries during the modern period. In some cases, these were pregnant women, with the fetus located in the pelvic cavity. In other cases, the mother and child most likely died during childbirth. The fetus, having emerged from the mother's womb, was buried with her in the same grave, often in the same container.

The number of archaeological finds of these burials does not reflect the reality of these simultaneous deaths, and it is difficult to quantify them because maternal and infant mortalities are always studied independently. At the same time, the funeral treatments observed for these deceased reveal a distinction that raises questions about the perception of death appearing during gestation and childbirth. To what extent is the burial of a pregnant woman considered as a double burial? How does modern society view these deaths? And when the birth leads to a double death, what criteria are used to allow a double burial of mother and child?

In eighteenth-century La Rochelle, these two types of double burial were present in both Catholic and Protestant cemeteries, discovered in recent excavations (between 2010 and 2023). Although they did not function in accordance with the same requirements and restrictions linked to different conceptions of Death, the presence of these burials could reveal a particular and irregular treatment chosen according to criteria specific to the biological identity of the deceased and/or the time elapsed between the death of mother and child.

Compared with other French examples, these burials provide an opportunity to discuss mother-child mortality and the different burial practices that arise from it.

13 DOUBLE BURIAL CASES. LOOKING FOR APPROPRIATE RESEARCH QUESTION(S)

Morintz, Alexandru (Institute of Archaeology, Bucharest) - Kogalniceanu, Raluca (1 Decembrie 1918 University, Alba Iulia, Romania) - Stirbu, Francesca (Institute of Archaeology, Bucharest, Romania) - Vasile, Gabriel (Institute of Archaeology, Bucharest, Romania) - Vacalie, Radu (Valahia University, Targoviste, Romania) - Coman, Marian (University of Bucharest, Romania)

Double burial is a non-representative funerary practice but significantly present almost anywhere and anytime in the world. What could be the meaning of a specific type of double burial or, turning the things around, what could be the question to which the answer is a specific type of double burial? Obviously, the variety of double burials involves a variety of questions and answers to match. Finding the right answer fit to a specific case could be a real challenge. But finding more and more pairs of matching questions and answers can give us some explanations about this non-normative funerary practice.

Our case study relies on ten double burials found in a medieval burial ground from Wallachia, dating between the end of the 14th century and the beginning of the 17th century. All ten graves were grouped in a small area. Five of them could be dated (with coins) in the first quarter of the 15th century. Except three of them, wealthy burial goods were found in all the graves, including coins, rings, buttons and other clothing accessories. The age and sex of the individuals buried together in the same grave included a wide variety of combinations: children, adolescents and adults, males and females. No unhealed mechanical trauma has been found on the bones.

Why this non-normative ritual practice was applied once and never again in this burial ground? Are all ten double burials related to the same event? Do all these people belong to a minority of the community? In our paper we will try to put more questions in order to find those who fit our material context. As the famous virologist Jonas Salk said, „What people think of as the moment of discovery is really the discovery of the question”.

14 THE MULTIPLE BURIAL BENEATH THE HUSABY MONUMENT - AN EXAMPLE OF A 13TH-CENTURY SOCIO-POLITICAL STRATEGY

Nyqvist Thorsson, Anna (Västsvensk arkeologi)

In Husaby in the western part of Sweden, an exclusive sandstone grave monument from the 13th century turned out to cover a complex burial context. Beneath the slim cover slab the remains of five buried individuals, two men and three women, were found. Multiple burials from the medieval period in Scandinavia is not an unknown phenomenon, but in general they are interpreted from the common hypothesis that burials of more than one individual in a single feature happen because of either biological relatedness, or contemporaneous or near-contemporaneous death.

At the moment, we can't be certain that the individuals from the Husaby burials are not biologically related, but it is obvious that the different funerals are separated in time. The first grave was re-opened for later interments more than a hundred years after the first burial.

Drawing upon the Husaby burials as an example, I will argue that a multiple burial can be interpreted as something more than creating a family grave in a prominent place within the cemetery. Instead, I argue that the re-use of an older grave can be perceived as a deliberate and conscious choice to establish a link to the past and to a person with a prominent position in society. The funeral was a social act and a performance that had an important role in creating or reinforcing social structures. Through this act, the burial of the dead in close physical relation to the older grave/graves were witnessed by the community. In the presence of an audience, both the dead and the surviving family were drawn into past relationships and processes connected with social influence and position.

15 LINEAGE LANDSCAPES OF THE DEPARTED: EXPLORING PORTUGAL'S DIVERSE FAMILY, POWER AND SOCIAL RELATIONS

Casimiro, Tania (FCSH-UNL) - Santos, Joel (University of Leicester)

In 1835, a new law in Portugal forced every city and village to build cemeteries with well-defined characteristics: a walled place had to be able to have large tombs, permanent graves, and temporary graves. This legislative decree marked a pivotal shift, as it became compulsory nine years later to bury the deceased in a cemetery, and church burials became forbidden. Thus, many cemeteries were built in the mid-19th century, either in large urban centres or small rural areas. These spaces necessarily reflected the size, social fabric, and cultural aspects of the places where they were created.

Most of the tombs found in these burial grounds are collective family tombs, and most of the time, they reveal the family relationships between the people buried inside these tombs or even with other tombs. Husband, wife, mother, father, son, daughter, cousins, and grandparents reflect how families engage in personal and social relationships. Considering regional differences, this paper aims to analyse several cemeteries in different areas of Portugal, some with a strong cultural identity, and how family bonds, and the power they represent, were maintained after death. In this sense, we analysed urban and rural, but also coastal and inland areas across the country comparing more than 50 cemeteries. We evaluated large and small burial grounds, discussing if social representation and cultural behaviours, towards age and gender reflected family connections. This will permit us to comprehend if different locations and the social and cultural behaviours of those places, associated with major superstructures such as religion, would influence such family behaviours towards death.

16 VIKING AGE MASS GRAVES C.1000: COMPARATIVE ANALYSIS OF THE TRELLEBORG, RIDGEWAY HILL, AND OXFORD CASES

Baillie, Britt (Roskilde Viking Ship Museum; McDonald Institute for Archaeological Research, University of Cambridge)

There are three known Viking Age sites containing 'mass graves' dating to c. 1000. The two 'collective graves' at Trelleborg were excavated in the late 1930s. Located in a cemetery that predates the establishment of the fort, the deceased were initially interpreted as thralls and subsequently as fallen warriors. The other two mass graves are located in southern England and were discovered in 2008 and 2009. The St. John's, Oxford case has been interpreted as being the result of the St. Brice's Day Massacre. Here, at least 35 individuals bearing multiple wounds from a 'frenzied attack' were unceremoniously deposited in a Neolithic henge ditch. Interpretations of the Ridgeway Hill, Dorset case, containing around 50 individuals placed in a reused Roman quarry pit, have ranged from the execution of mercenaries/warriors/hostages to a different permutation of the St. Brice's Day Massacre. This paper will explore what a comparative analysis of the aDNA, isotope data, contexts, trauma and antemortem data reveal about the identities of the deceased and the phenomenon of 'mass graves' around the shift in the millennium.

17 BURIED WITH A STRANGER BUT A BATTLE-MATE: A CASE STUDY FROM SARDIS

Özer, Füsün (Human-G Laboratory, Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey; Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey) - Altınışık, Nefize (Human-G Laboratory, Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey; Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey) - Kazancı, Duygu (Department of Biological Sciences, Middle East Technical University, 06800 Ankara, Turkey) - Cahill, Nicholas (Department of Art History, The University of Wisconsin, Madison, WI, USA) - Somel, Mehmet (Department of Biological Sciences, Middle East Technical University, 06800 Ankara, Turkey) - Erdal, Yılmaz (Human-G Laboratory, Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey; Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey; Husbio-L Laboratory, Department of Anthropology, Hacettepe University, 06800 Beytepe, Ankara, Turkey)

Multiple burials have been a subject of long debate in anthropological literature. The coexistence of more than one person in an interment is mostly evaluated within the framework of social and/or biological kinship and cultural spheres. Two adult individuals with multiple perimortem wounds were interred simultaneously in the same simple pit grave in Field 49 of the ancient city of Sardis in Manisa province of Turkey. These individuals, buried according to Islamic tradition, were found next to a Christian cemetery. Radiocarbon dating confirmed that individuals buried following Islamic and Christian traditions were contemporaneous (1030-1150 cal. AD and 1016-1158 cal. AD, respectively).

Here, we explored the story of these individuals by using a multidisciplinary approach. We obtained genome-wide data for the two individuals, which showed that both were genetically male. We then performed Principal Component Analysis to study their populations of origin. We found that both genomes cluster with Medieval Anatolian genomes and carry some degree of Central Asian affinity. We also formally tested their genetic ties with surrounding populations.

Next, we explored the genetic kinship between two individuals. We found that they did not share the same mitochondrial DNA and Y-chromosome haplogroups. Autosomal DNA data also did not support genetic kinship between these two males. Our results imply that genetically unrelated two males were buried together probably as they were the victims of an act of violence and died at the same time. The violent deaths of the Turkish invaders in western Anatolia, encountered by the local Christian group could be one of the explanations why these individuals were buried together in the same pit. In summary, apart from social or biological kin relations, social phenomena such as martyrdom or violent death might also be a reason for co-burial.

18 LINKED BY DEATH: DOUBLE BURIALS IN AN EPIDEMIC CONTEXT

Castex, Dominique (CNRS) - Kacki, Sacha (CNRS)

For the medieval and post-medieval periods, double burials are divergent from the regular funerary practices, but they are nevertheless quite often identified in the archaeological record. With a few rare exceptions, this type of burial indicates the simultaneous death of two individuals who were subsequently buried together in the same structure. The circumstances leading to concomitant deaths can be relatively common, and may differ depending on the geographical or chronological context considered. They may be occasional events (e.g. maternal-foetal death during pregnancy or childbirth, hierarchical deaths, small collective accidents) or, on a larger scale, mortality crises, whatever their causes. In this presentation, we will address the question of the use of double burials in epidemic contexts, by reviewing the archaeological evidence we have accumulated over the last few decades of the presence of such graves in burial sites from the early Middle Ages to the early modern period. We will examine the factors that, depending on the site or region, led to the creation of double burials rather than mass graves in this context of mortality (chronological context, rural versus urban environment, beginning and/or end of the epidemic).

1050 REDEFINING ABANDONMENT: GEOARCHAEOLOGICAL AND ETHNOGRAPHICAL APPROACHES TO UNVEILING HIDDEN NARRATIVES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Banerjee, Rowena (University of Reading) - Morandi, Lionello (University of Pisa) - Sciuto, Claudia (University of Pisa)

Session format: Regular session

Abandonment is synonymous with processes and acts such as desertion, neglect, disuse, and evacuation. Historical and ethnographic evidence shows that periods of abandonment encapsulate pivotal social and economic changes in the biographies of human settlements. Abandonment processes arise from cultural, economic and environmental transitions in human history and the temporality of these processes can vary, but they are often only described as a 'book-end' to an archaeological narrative and rarely a topic considered worthy of discussion. This gap in understanding is perhaps due to an initial focus in processual archaeology on it being a process by which something becomes

archaeology, implying cessation and “end of life”, rather than the agency of those processes. Far from just creating “empty” settlements, abandonment processes also generate a novel view of seeing and perceiving the landscape in the local population. Shifting the focus in the examination of abandonment involves a move away from seeking centralized causes and instead emphasizes the observation of how the interactions between humans and non-humans evolve over time and space (Pétursdóttir, 2014).

The aim of this session is to examine, through geoarchaeological and ethnographical approaches, how archaeological sites, monuments, and landscapes can be in flux, their states of periodic abandonment and re-use, but also the processes and events resulting in (and from) complete abandonment.

We welcome papers focusing on:

- Theoretical and methodological viewpoints attributing new meanings to abandoned areas, also from a non-anthropocentric perspective.
- Geoarchaeological investigations bringing new data for the understanding of both agencies and formation processes in abandonment, also with the contribution of a comparative perspective from ethnoarchaeological data.
- Ethnographical and community archaeology aimed at the disentangling of identities and memories linked to the abandoned spaces.

ABSTRACTS

1 ECHOES OF THE PAST: EXPLORING THE LEGACIES OF THREE ABANDONED SETTLEMENTS IN THE FAROE ISLANDS

Villumsen, Melissa (University of Aberdeen; Museum Thy)

This paper delves into the legacies of three abandoned settlements in the Faroe Islands; Korndalur (late 17th or early 18th century), Blankskáli (early 19th century), and Skarð (early 20th century). Through engagement with descendants, the relationship between these settlements and local communities and descendants is examined. The enduring collective memories of the abandoned settlements persist in both tangible and intangible forms, indicating the significance of maintaining a connection to this part of their shared heritage.

Physical traces of the abandoned settlements persist not only in their original locations as ruins, but also within the walls of inhabited buildings in the communities to which they were relocated. Despite having been abandoned over 300 years ago, artefacts and remnants from Korndalur are integrated into daily life by locals in the neighbouring community. The houses of Blankskáli were relocated in their entirety after an avalanche, and the ruined settlement continues to shape the identity of the new settlement. Skarð stands out as the settlement whose memory has been most actively preserved. In 2013, over 500 people gathered there to erect a monument commemorating the boat accident that led to Skarð's demise 100 years prior.

This paper not only highlights the lasting legacies of the settlements but also examines the environmental, societal and economic changes that led to their abandonment. Moreover, it emphasizes the importance of understanding how past cultural landscapes are perceived and interpreted in the present Faroese society.

2 DIGITAL DOCUMENTATION AND GEOARCHAEOLOGICAL ANALYSIS OF THREATENED HISTORICAL VERNACULAR ARCHITECTURE IN CYPRUS

Elliott, Sarah (Bournemouth University) - Manley, Harry (Bournemouth University) - Hadjisterkotis, Eleftherios (Agricultural Research Institute, Cyprus)

This research project started with the concept of using modern abandoned villages as an analogy for Neolithic villages in the Middle East. However, what soon became apparent was that due to their episodic abandonment, there was a fundamental need to record these historical abandoned villages, and their associated liminal landscape, in their own right.

While UNESCO recognises the art of building dry stone walls in Cyprus, it overlooks the precursor to this form of construction: mudbrick architecture. This material was common in traditional villages throughout the Middle East and represents a threatened form of vernacular architecture, with substantial portions of now-abandoned villages being constructed from mudbrick. Utilising digital methodologies such as 3D laser scanning, drone-based photogrammetry, and GNSS surveying, this study has recorded the threatened traditional vernacular architecture in Cyprus, as well as carrying out sampling of construction materials and activity areas for geoarchaeological analyses (geochemistry, phytoliths, animal dung).

A successful pilot study across four abandoned villages has validated our digital recording and mapping approach. By combining the results of the digital survey with data from historic aerial photographs and cadastral plans, the investi-

gation examined the temporality of abandonment. It has identified the continuation of religious practices in structures within the uninhabited villages, highlighting ongoing cultural affinity with these seemingly abandoned places.

In addition to the scientific analyses and digital recording, this research also aimed to raise awareness of the islands' historical architecture which is susceptible to loss through natural and anthropogenic destruction, such as disuse/neglect, and currently that is not protected by antiquity laws. Therefore, this research collated a broad archive of material, which included the intangible ethnographic histories relating to construction, use and abandonment: the full life cycle of a Cypriot village.

3 ABANDONED POTTERY WORKSHOPS: A GEO-ETHNOARCHAEOLOGICAL STUDY OF A CONTEMPORARY POTTERY-MAKING VILLAGE IN THE WESTERN LOESS PLATEAU, CHINA

Lin, Siyu (Durham University) - Milek, Karen (Durham University)

Soil micromorphology analysis is invaluable for studying ancient human activities, yet there has long been a lack of micromorphological research on the remnants of pottery production in archaeological sediments. Using field surveys and soil micromorphological studies in Yaotou, Gansu, China, this research is identifying diagnostic characteristics of pottery production and is enhancing our understanding of pottery production from an ecological perspective. The abandoned pottery production area is in and around traditional loess house dwellings (Yaodong). With its ability to maintain a consistent temperature and humidity, it is well-suited for pottery manufacturing. Different pottery-making facilities, including places for raw material piling, pottery building, drying, and storing, interacted with each other, creating a complex workflow. Thin sections sampled from the waste area exhibit various features from the entire chaîne opératoire of pottery making. Red clay, rich in high kaolinite and smectite, was deliberately selected and mixed with loess to obtain the appropriate pottery paste, while mineral grains were intentionally added as tempers to achieve the desired paste consistency. The heterogeneous distribution of quartz and feldspar shows mixing and manufacturing in the sample are still at the primary stage. Vitriified ash indicates the high temperature necessary for pottery firing, which reached over 800°C. The presence of charcoal and wood ash provides insights into the types of fuels employed, following the principle of cost-effectiveness. By integrating macro and micro scales, this study reconstructs a narrative of abandoned pottery manufacturing, holding significant implications for identifying and interpreting this craft in archaeological contexts, especially in on China's Loess Plateau.

4 NOT QUITE-ABANDONED: NATURAL DISASTERS AS AGENTS OF USE AND RE-USE OF SPACES

Angelo, Dante (Universidad de Tarapacá) - Rojas, Néstor (Universidad de Tarapacá)

Our paper analyzes an archaeological and historical site in northern Chile, which has been hit by violent natural disasters. Throughout their history, human settlements on the coast of the Atacama Desert have been subject to frequent transformations caused by natural disasters. However, this dynamic condition has seldom been considered from a perspective of constant change and reuse of meaningful spaces. Here, through a multi-scalar analysis that considers: 1) processes of site formation of a historic site, derived from tsunami, flood and earthquake events, and, 2) ethnographic documentation that recounts its transformations as a historic cemetery, an emergency refugee camp and a baseball field, among others, we aim to shed some light about the role of disasters as active agents engaging in processes of occupation, abandonment, transformation, and replacement of inhabited spaces. By proposing a roughly defined charting of these interactions (human-nonhuman) we hope to contribute to the theoretical discussion on the biography of (re)used spaces.

5 “LEAVING TO OCCUPY AND OCCUPYING WITHOUT INHABITING”, THE EXAMPLE OF THE EXPLOITATION OF A VALLEY IN THE AUVERGNE MOUNTAINS (PUY-DE-DÔME)

Cocoual, Antoine (University of RENNES 2)

“Settlement, occupation and abandonment” - three states that characterize a site's period of activity from an archaeological point of view. This technical and abstract perception reflects a materialistic and dehumanized vision of reality. Indeed, the end of a settlement does not necessarily mean the death of the human community that occupied it, or the cessation of activity at a regional level.

Beyond these few observations, abandonment is sometimes the sign of a societal transformation and a precious indicator in the understanding of the evolution of human settlement on a global scale.

In Auvergne's Sancy massif, the succession of human occupations in the Couzes valley reflects the evolution of land management strategies from protohistory to the present day. In the Middle Ages, the relocation of settlements to the slopes did not mark the abandonment of the valley and the plateaux, but rather reflected a new mode of territorial administration, responding to the emergence of new political powers and changing agrarian practices.

Recent research highlights the gradual transition from fragmented management to integrated management of the entire mountain territory.

6 AFTER THE INDUSTRY: REINTERPRETING ABANDONED INDUSTRIAL LANDSCAPES IN POOLE HARBOUR

Manley, Harry (Bournemouth University) - Elliott, Sarah (Bournemouth University) - Pitman, Derek (Bournemouth University)

What happens to industrial sites after they go out of use? In the UK, areas related to abandoned industrial activity are often referred to as “Brownfield sites” and are negatively perceived as areas with high contamination and little post-abandonment value. Furthermore, archaeological surveys of historic industrial sites frequently use language laden with negative connotations such as “waste tips”, “spoil dumps” and “slag heaps”, with little consideration given to the inherent value of the by-products of the industrial processes.

Should we, then, begin to rethink “abandonment” at these archaeological sites and consider a longer, post-industry biography at them? What happens to the structures and surrounding landscape after the industrial processes end? Do they afford resources that enable the landscape to evolve into something new and different, and, if so, are we able to detect this archaeologically?

Recent archaeological evidence from excavations on the edge of Poole Harbour (Dorset, UK) suggest that the “waste tips” from medieval salt production were utilised as a resource to create agricultural fields for cereal production and pasture. A programme of deposit modelling using topographic data, sedimentology and geochemistry explored the wider landscape around the salt production site, revealing that, far from becoming a post-industrial abandoned waste ground, the landscape was heavily anthropogenically modified to create the rural idyll that it now is. The natural character of the Poole Harbour catchment, as visible today, is therefore the result of a complex relationship between past coastal communities, natural resources and the by-products of historic industrial processes. This study shows that the extent of the impact of human activity is often greater than the focal points of activities themselves and highlights the need to reconsider how we perceive “waste” in the archaeological record.

7 SIGNATURES OF ABANDONMENT IN THE MICROARCHAEOLOGICAL RECORD

Banerjee, Rowena (University of Reading) - Morandi, Lionello (University of Pisa)

The portrayal of abandoned spaces was reconsidered by Hudson (2014), who uses the term ‘informal spaces’ to refer to derelict spaces and ruined sites collectively, which fulfil several roles for different people. Our data show that identification of signatures in the microarchaeological record can provide localised, micro-contextual spatial and stratigraphic information on depositional and taphonomic processes to examine terms such as “informal spaces”. These processes can be indicated by soils formed on substrates of anthropogenic layers, fluctuations in the abundances of microscopic activity residues within deposits that may indicate “sterile” wind and waterlaid deposits, and the gradual dilapidation of structures. This microarchaeological information helps us to understand the processes by which something becomes archaeology following cessation or “end-of-life” of structures and occupation, and the agency behind those processes, and, in particular, identifying localised abandonment within settlements, timescales of widespread abandonment across the settlement (and landscape), hiatuses in the use of structures or temporary abandonment, and the nature of any “post-abandonment” (see LaMotta & Schiffer 1999) activities within structures.

Starting with examples of abandonment, partial abandonment and “end-of-life” processes from ethnoarchaeological sites from the Alpine and Apennine regions, Italy, this paper then presents examples of soil micromorphological and microfossil data from experimental archaeological sites, urban archaeological sites and peri-urban historic landscapes, which may represent these stages in the archaeological record. The experimental sites include Lejre Historical and Archaeological Research Centre, Denmark, and Butser Ancient Farm, UK, and the archaeological case studies include data from Silchester Roman town, UK, and the “Land of Aynadamar”, Granada, Spain. The results from our data help to redefine areas termed as abandoned spaces, as well as to understand both agencies and formation processes in abandonment.

8 ABANDONMENT AND ARCHAEOLOGICAL ASSUMPTION: ETHNOARCHAEOLOGICAL EXPLORATION OF SETTLEMENT ABANDONMENT IN WEST KARBI ANGLONG, NORTHEAST INDIA

Sabnis, Shikharani (Christian-Albrecht University)

Humans respond to new circumstances, such as climate change, environmental degradation caused by human activity, or social challenges by relocating and abandoning their current settlements. Abandonment can occur at various scales, from individual activity areas to entire regions. While all archaeological sites have experienced abandonment, the manner in which structures or settlements are left behind varies significantly.

Northeast India stands out as one such region where our understanding of the origins and migrations of prehistoric communities remains incomplete. The rugged terrain and the considerable time needed to identify potential locations of prehistoric settlement sites present significant challenges. Ethnoarchaeology has re-emerged as a key methodo-

logical tool in recent years for comprehending the past cultures of a particular area. Drawing upon data gathered during recent fieldwork in the hilly district of Assam, Northeast India, focusing on the diverse uses of material culture for consumption, social interaction, and political purposes, this paper aims to explore the reasons and processes behind the abandonment of structures, activity areas, and settlements. Among the ethnic groups inhabiting the region, the motivations for these abandonments may extend beyond environmental or resource-related factors to encompass economic, social-political, and belief-system considerations.

Through this contribution, we seek to understand not only the settlement patterns of the early settlers of the region but also potential pathways for future research and deepen our understanding of this complex and intriguing region.

9 BEYOND ABANDONMENT: A MULTIVOCAL EXPLORATION IN THE APUAN ALPS

Sciuto, Claudia (University of Pisa) - Anichini, Francesca (University of Pisa) - Basile, Salvatore (University of Pisa) - Gattiglia, Gabriele (University of Pisa) - Giovannetti, Chiara (University of Roma, La Sapienza)

Redefining abandonment demands a comprehensive strategy that encompasses various perspectives within the archaeological palimpsest. The decentralisation of human exceptionalism is necessary for a paradigm shift in considering abandonment as a context in which humans, non-humans, memories and materialities intertwine to create new assemblages.

While archaeological theory has dealt extensively with the importance of a holistic approach to analysing the archaeological record, it often remains unclear how archaeological practice can adapt to these instances of horizontality. From our point of view, a multivocal and transdisciplinary approach can be used to narrate the complexity of interactions that unfold in the context of abandonment. Archaeological surveys and environmental archaeology can dialogue and interrelate with the experiences of the communities that, in various ways, traverse abandoned territories.

The presentation will focus on the example of research conducted on the Versilian slopes of the Apuan Alps, in north-western Tuscany. Different strategies involving various focus groups led to descriptive approaches, creating a multivocal picture. A series of interviews were conducted with members of the local communities, which provided insight into details of production and livelihood practices, such as forest management techniques, terracing cultivation, and charcoal production. Collective mapping with adults and children, on the other hand, was carried out during specific walking events, providing participants (mostly from lowland towns) with maps on which they could record experiential notes and associations with personal memories related to the walk. Lastly, the project conducted with the Martiri di Sant’Anna school, located in the village of Sant’Anna di Stazzema, involved primary and secondary school children in a two-year course that resulted in an exhibition set up by the children on places, objects and memories of the abandoned mountain.

10 PASTORAL UPLAND LANDSCAPES: LAND USE, (OVER)GRAZING AND ABANDONMENT FROM ETHNOARCHAEOLOGY AND COMPUTATIONAL ARCHAEOLOGY. A CASE STUDY IN THE ASPROMONTE (ITALY)

Domingo Ribas, Guillem (Newcastle University) - Carrer, Francesco (Newcastle University) - Romanowska, Iza (Center for Humanities Computing (CHC), University of Aarhus)

Pastoralism is regarded as one of the most extensive forms of land use on Earth, and millions of livelihoods worldwide depend on it. Particularly relevant in upland spaces, where agricultural practices are less likely to succeed, mobile pastoralism permits the exploitation of remote areas generally during the summer season, triggering landscape change, influencing local ecologies, and shaping landscape character for centuries in remote mountain spaces. Mountain landscapes in the northern Mediterranean are representative of these dynamics, and agropastoralism is still the main human activity despite the severe depopulation and the socioeconomic issues faced over the last decades.

Our contribution will explore one of such agropastoral systems: an abandoned village in the Aspromonte Massif (Calabria, Italy). Africo Vecchio was a village whose main economic activities were focused on pastoralism and transhumance mobility, and whose population lived under conditions of extreme poverty, isolation, and severe weather until a landslide triggered the abandonment and relocation of the entire village in 1954. Through the combination of ethnoarchaeological fieldwork, participatory events, and computational modelling, it has been possible to understand the functioning of this pastoral system and the social reality of these mountains during the 20th century. An agent-based model to simulate pastoral mobility and grazing strategies has been developed to simulate different scenarios, assess the sustainability of the pastoral system and unravel the underlying socioeconomic dynamics that led to its collapse and the abandonment of the area, which will be the focus of the contribution. At the same time, our paper will also cover how close work with the local communities has ensured the preservation of threatened local knowledge, informed policymakers, and, above all, revived the local community’s interest in its pastoral past and its abandoned village.

THE END IS NOT THE END: BUILDING ABANDONMENT PROCESSES DURING THE NEAR EASTERN NEOLITHIC

Garcia-Suarez, Aroa (ArchaeologyHub.CSIC)

The onset of sedentism at the beginning of the Holocene is best manifested in the mudbrick architecture that characterises the Near Eastern Neolithic. Understanding the processes that led to the construction, use and abandonment of domestic built environments in the first villages are critical to the reconstruction and interpretation of their spatial organisation. However, while building construction and use has attracted significant scholarly attention, abandonment phases are often overlooked, excavated in large arbitrary units and rarely sampled.

This paper focuses on the geoarchaeological examination of building abandonment sequences from Neolithic sites in Jordan and Türkiye spanning ca. 9000–6000 cal BC. This study has found that building abandonment phases are frequently demarcated by symbolic deposits, partial destruction of the external walls and features, often with the purpose of reclaiming and re-utilising specific construction elements, and deliberate infilling. Micro-stratigraphic analyses have revealed that, while some abandoned buildings are filled with compact, single-event packing deposits, others function as both activity areas and/or locations for the dumping and accumulation of domestic waste.

This research shows that the reasons for the abandonment and demolishing of domestic built environments are often unclear, and could have been related to ritual re-building beliefs and processes, where a new house is erected on the remnants of an earlier house. Thus, in the Near Eastern Neolithic, abandonment does not simply represent the end of a particular building's life-history, but the beginning of a new one.

1052 REVIEWING THE 2020 MERC MANIFESTO ? CHECKING IN ON THE FUTURE DIRECTION OF MEDIEVAL ARCHAEOLOGY IN EUROPE

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Crabtree, Pam (New York University) - Lewis, Carenza (University of Lincoln)

Session format: Round table (without formal abstracts)

Astonishingly, the Manifesto of the Medieval Europe Research Community (MERC) (Medieval Europe Research Community (mercmanifesto.org)) will be five years old in 2025. The 2020 Manifesto aimed to nurture medieval archaeology (defined in broad chronological and geographical terms), in light of its particular visibility, ubiquity, familiarity and resonance, reflecting the priorities of the EU's 2005 Faro Convention (The Value of Cultural Heritage for Society) and EAA's 2019 Bern Statement (Archaeology and the Future of Democracy). Hence the 2020 Manifesto's purpose was to foster a medieval archaeology that transcends borders, collaborates across sectors, engages publicly and contributes sustainable benefits to wider society. The Manifesto's guiding principles were that this could be achieved through a virtuous cycle in which advancing knowledge of medieval archaeology increases appreciation of its value, which encourages its care and protection, which increases public engagement and enjoyment, which completes the cycle by building capacity for further advancing knowledge. The Manifesto ended with six priority recommendations: 1.Challenge the political misappropriation of medieval archaeology; 2.Promote STEM archaeological careers; 3.Increase capacity in planning and museums; 4.Invest in human resources; 5.Make research openly accessible and collaboratively co-created; and 6.Increase public engagement.

Any manifesto should be periodically reviewed to ensure it remains relevant. The 2020 MERC Manifesto was mostly drafted in what now seems like another era, before COVID19, war in Ukraine, the cost-of-living economic crisis and a myriad of other political, social and economic difficulties the 2020s has already experienced.

Accordingly, EAA2024 seems an appropriate time to review the progress made towards advancing or meeting the 2020 Manifesto priorities, aims and recommendations, review their continued relevance and whether new priorities have arisen, and consider whether any changes to the 2020 manifesto are needed to ensure it can nurture medieval archaeology and wider society into the second half of the 2020s.

All welcome.

1054 LANDSCAPE ARCHAEOLOGY AND PLACE NAMES IN MULTIFOCUS INTERPRETATIONS

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Klir, Tomas (Charles University, Faculty of Arts, Department of Archaeology) - Janovská, Viktorie (Charles University, Faculty of Arts, Department of Archaeology) - Wawrzeniuk, Joanna (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw, Poland) - Vieira, Alexandra (CITCEM.FLUP and Instituto Politécnico de Bragança, Portugal)

Session format: Regular session

The session aims to bring together scholars dealing with archaeology, onomastics, ethnography, oral tradition and other related fields from all parts of Europe to provide a space for discussion and sharing ideas concerning the study of the landscape. Changes or persistence of the settlement patterns influenced by migrations, population resettlement and other social and economic aspects can be studied on the basis of geographical names in various regions. The interdisciplinarity reveals new approaches to study populations which passed through Europe within prehistoric and historic periods. Overlapping layers in the landscape are explored in their material and immaterial dimension by different approaches in every country, the richness of which will be presented by researchers of various fields.

Different contributions will address the following questions:

- What interdisciplinary methods can be used to reconstruct the past cultural landscape? What is the current state of cooperation between landscape archaeology and onomastics in the humanities?
- How can onomastic and archaeological records be used to trace changes or persistence of settlement in the landscape?
- What contact zones, as regions in which the transmission of diverse material culture and multilingualism took place, bring new knowledge?
- Does oral tradition help in the interpretation of the archaeological sites and features? How can we create a biography of a place?
- What kinds of archaeological monuments can be discovered by the study of geographical names? What is the meaning of the etymology and etiological legends related to the place names?

ABSTRACTS

1 GIVING MEANING TO A NAME: HOW THE STUDY OF PLACE NAMES CAN CONTRIBUTE TO THE ARCHAEOLOGICAL READING OF LANDSCAPE

Matteazzi, Michele (University of Trento)

This paper intends to highlight the important contribution that research on place names can bring to the archaeological studies on landscape, by analyzing some examples we can nowadays find within the province of Trento (Italy). Toponymy, thanks to a comparative analysis of ancient and modern place names, can bring to: identifying a series of features or functionalities (both anthropic and environmental) today no longer recognizable and referable to past landscape structuring, dating from Protohistory to the Modern Age; finding settlements and artifacts whose traces have been lost over the centuries; recognizing a continuity or a change in settlement patterns. From a methodological point of view, we can distinguish two types of approach, different but complementary to each other, which we can define as "areal" and "stratigraphic". The former considers an investigation extended over a large area, thanks to which it could be possible to establish the spread of one or more place names that belong to the same linguistic group. Instead, the second one analyses the different names of a same place considering their linguistic layer of belonging, their chronological succession, and their degree of resistance to the influence of more recent linguistic groups. The final aim is to give (or to give back) a meaning to the place names that define the current landscape, analyzing their genesis and development. The name of a place was always born with a particular meaning, given to highlight some physical feature of the area, the presence and/or function of anthropic artifacts (buildings, roads, channels...), or the ownership of the land. However, very often this original meaning has been lost over time due to its archaicity because it belongs to linguistic layers that are no longer existing and therefore now incomprehensible, moving away from a phase of meaning to that of indicating or identifying.

2 THE ROYAL INAUGURATION SITE AT MORA, SWEDEN: LANDSCAPE STUDY THROUGH ARCHAEOLOGY AND PLACE NAMES

Bäck, Mathias (The Archaeologists, National Historical Museums) - Sanmark, Alexandra (Institute for Northern Studies, University of the Highlands and Islands) - Lindeberg, Marta (Swedish National Heritage Board) - Jonsson, Kristina (Jamtli, Museum of Jämtland)

This paper will discuss the methodology and early results of the ongoing research project focusing on Mora, the inauguration site for kings of medieval Sweden referred to in documents from the late 13th century to the 15th century, as well as on carved stones found around the site. Mora is situated a few kilometres southeast of Uppsala Cathedral where the coronations were held after the inauguration rituals. Mora has drawn much attention from scholars and ecclesiastical dignitaries of varying disciplines, from the 15th century until the modern day, but despite these efforts the exact location of the inauguration site has not been identified with any certainty. This is indeed a difficult task, due to a general lack of clearly identifiable archaeological remains and the vague nature of the written sources. In order to establish how the site was used for the medieval inaugurations, this project takes a wide-ranging approach via a full landscape analysis, using a combination of methods, such as geophysical survey, excavations, and detailed place name analysis. It is shown that the toponymy can provide much information about older water levels at site, which is used to aid the landscape reconstruction. Further placenames also provide insight into nearby key locations and communication routes used for reaching the inauguration rituals.

3 SACRED WATER IN PODLASIE (EASTERN POLAND) - PHENOMENA FROM THE PRE-CHRISTIAN PERIOD?

Wawrzeńnik, Joanna (Cardinal Stefan Wyszyński University in Warsaw) - Józefów-Czerwińska, Bożena (Academy of Aleksander Gieysztor in Pułtusk - Branch AFiBV)

In the sources of Podlasie folklore relating to the codes of belief culture, a particular attitude to nature was marked. Life was even seen in such elements as water. However, specific categories of water were distinguished and related to the relationship with the sacred, which could have a varied structure. For example, water that came into contact with the body of the deceased was marked by the order of death. Such kind of water for the living was dangerous. Water from springs or wells located within the boundaries of sacred sites - was connoted as a positive kind of sacrum. This was evidenced by the belief of the oldest respondents and in the oral tradition of this region that it could free people from disease or other misfortunes. There was, however, a condition. When washing in the miraculous water, according to the oldest inhabitants of Podlasie, one had to say or think of a request, an intention addressed not only to God, but directly to the water. It can be assumed that this attitude towards water dates back to pre-Christian beliefs, where water as an element of nature as a well was an important component of the cult landscape. We will also illustrate these phenomena during our presentation.

4 TRACING THE ROYAL DOMAIN WITHIN MEDIEVAL COUNTY OF ZAGREB

Antonic, Nikolina (Department of Archaeology, Faculty of Arts, Charles University) - Simon, Suzana (Institute of Historical and Social Sciences, Croatian Academy of Sciences and Arts)

At the end of 11th century medieval Slavonia became a unit within composite Kingdom of Hungary. The (rare) first extant written sources concerning the area date from the second half of the 12th century/first half of the 13th century. Their number starts to increase after 1242. Newly joined territory was divided into counties and smaller units, castle districts centered around certain castles. At the same time, kings were giving significant portions of land to the church, high nobility, religious orders etc. However, in both Croatian and Hungarian scholarship, the origin of these territorial organizations was much debated.

This presentation aims to approach the topic from a different angle, using medieval Zagreb County as a study case. Instead of theoretical discussions, county of Zagreb will be looked through detailed spatial analysis. This includes, on one side mapping of toponyms and boundaries recorded in medieval charters, and on the second, mapping castles around which castle districts were formed. First it will be shown to what extent is possible to establish the exact borders of the county and particular castle districts based on the sources. Second, it will be discussed if analysis of spatial positions of castles enables new insights into the process of forming of castle districts. Third, it will be shown what parts of the land within the County remained directly in royal domain in the later centuries. Finally, it will be questioned if there is any spatial "logic" explaining why kings kept some parts of land directly under their rule and how this fact influenced development of areas in the modern period.

5 NAMES OF POWER: THE STUDY ON PLACE NAMES OF SLAVIC STRONGHOLDS IN THE CONTEXT OF MEDIEVAL LANDSCAPE

Janovská, Viktorie (Charles University, Faculty of Arts, Department of Archaeology)

The toponyms of medieval central places and strongholds form the oldest layer of Czech words that we know from the written Latin sources. The focus of this paper is especially on names from *Chronica Boemorum* by Cosmas of Prague and other sources from the 12th century. There is presented a critical classification of place names related to power and administrative centres in medieval Bohemia. This topic is directly connected to the questions of the territorial development and raising centrality of the early Czech state. Some strongholds of the medieval administrative network still fulfil the role of regional centres today, while others have found themselves on the edge of settlement activity. This contrast in settlement changes on the one hand and the persistence of some centres on the other shows us the dynamics of the development of medieval settlement network. What mechanisms led to these different fates of power centres and what do their names tell us about these changes? Moreover, can the linguistic analysis of geographical names help us to recognize the names of strongholds that are not mentioned in written sources, but we know their archaeological remains? The distribution of centrality will be examined in relation to the chronological and topographical aspects, land and river routes, development of settlement processes and landscape transformation.

6 LANGUAGE AND BURIAL RITUALS ON THE CAROLINGIAN-OTTONIAN EMPIRE BORDERS

Klir, Tomas (Charles University, Faculty of Arts, Department of Archaeology)

The aim of this paper is to advance our understanding of the relationship between material culture, language and ethnicity using the example of the eastern frontier of the Carolingian-Ottonian Empire (8th-10th centuries), specifically what is today north-eastern Bavaria. On the basis of settlement names and hydronyms, it appears that this area was linguistically heterogeneous, where Slavic-Germanic language contact took place. Written sources mentioned ethnic 'Slavs', who were, however, not defined by language. Surprisingly, it seems that this language and ethnic heterogeneity was not expressed in the burial ritual of the time. Dozens of row skeleton burials are known from northeastern Bavaria (mostly also 8th-10th century), but at first impression they appear homogeneous across the whole area. The question is whether this view is correct. The paper presents the results of a new analysis of the archaeological sources and, particularly, a new interpretation using the testimony of written and linguistic evidence.

1056 TELLING THE STORIES OF OTHERS? ETHICS, EPISTEMOLOGY, AND PRACTICES IN ARCHAEOLOGICAL DISCOURSES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Moucheron, Martin (University College Dublin) - Nyland, Astrid (Museum of Archaeology - University of Stavanger)

Session format: Regular session

Reflecting on an appropriate use of analogy and ethnography is at the core of research practice for many archaeologists: we are fundamentally 'telling the stories of others', i.e. telling stories about Others - in their stead. Embedded in our stories are decisions to tell one in many possible ways of being human. This is always theoretically and politically situated and needs to be considered.

Ethical, epistemological, and practical implications of telling the stories of Others can be deployed around four questions:

Who: who speaks? In whose name? Who is talked about? Which stories are ours to tell? Which voices are present in archaeological texts? Is it possible to represent without misrepresenting? Is storytelling a way of voicing the not-yet-heard?

What: what link(s) are there between descriptions, narratives, stories, representations, and interpretations? Can one describe without interpreting? What do we choose to say about our fragmentary data? What is the effect of time and taphonomy on our interpretations?

Why: is anyone unsettled by the idea that archaeologists are storytellers? Why/why not? Is there a distinction between archaeological discourse and (other types of) storytelling? With the constructed separation between the scientific/objective/real/neutral world and that of imaginaries, stories and narratives, are we telling stories that would be (in)comprehensible to past populations?

How: How should we implement anthropological/ethnographic knowledge? To what extent can storytelling as knowledge transmission become a part of our research practice? Is there a difference between analogy from ethnographic/anthropological sources and appropriation of indigenous knowledge in our attempts to create sense from our data?

For this session, although research on hunter-gatherers is our point of departure, we welcome papers reflecting on how to represent all past people in ways that support ethical and respectful practices, and diverse narratives.

ABSTRACTS

1 STORYTELLING WITH OTHERS

Warren, Graeme (University College Dublin) - Moucheron, Martin (University College Dublin) - Nyland, Astrid (Universitetet i Stavanger)

Archaeologists are fundamentally 'telling the stories of others'. We are also always culturally, socially, and historically situated, which means that storytelling is always political. This makes it imperative to keep focus on how to secure ethical and respectful practices of telling other peoples' stories. That is, we need to pay attention to who speaks and in whose name? Who is talked about and how? Which voices are represented – or misrepresented – in archaeological texts?

Considering how we disseminate and present our data, storytelling as knowledge transmission is entangled in our research practice. Choices are made every day as to what to include or not empirically, but also how we choose to disseminate our work and the ways in which we practise it. Indeed, in many senses, the most important part is the process of storying, rather than the story. This is because Storytelling is key in the building or re-building of knowledge and relationships, and how we do it can thus challenge and shift established truths and categories of the world. There is power in this. Considering archaeologists as contributing to building worlds demonstrates that archaeological knowledge can contribute to knowledge production in current society, not only provide curiosa.

As a first experimental step, this introduction is a commitment to a process as well as to a result: we, as authors, have engaged in a continuous discussion on the topic based on a deliberate "respectful dissent" – i.e. we actively listen to each other's perspective, and do our best to integrate AND challenge it to move the discussion further; we can also count on the others to help us identify our respective biases. Our paper thus exemplifies our argument that storytelling with others builds knowledge and relationships, and creates categories of the world.

2 BEYOND SILENCE: EMPOWERING PORTUGUESE WOMEN IN INDUSTRIAL ARCHAEOLOGY

Pacheco, Susana (CFE-HTC Nova University of Lisbon) - Casimiro, Tânia (CFE-HTC Nova University of Lisbon)

The study of subaltern communities and groups is something that archaeology has been doing for a few decades trying to give a voice to those who were silenced for generations. But is it ethical to speak for them and assume we know what they want to say, and what they would want us to know? We are aware that for earlier periods we usually do not have much of a choice but to speak for them, interpreting anything we can find. It is either that or leaving them in complete silence forever. But what if we had the opportunity to let them tell their own stories? In contemporary archaeology, we often deal with historical subjects that are still alive, or at least were able to record their testimonies before dying. Besides, how will our interpretation of their lives change by letting them speak?

With this communication, we intend to do an exercise. By exploring first-person testimonies of women in the Portuguese industrial sector, we hope to clarify and debunk some myths related to their role as workers. At the same time, we intend to explore how memory and narratives about these subjects can be affected, and what is the practical political result of that. Usually, archaeologists are storytellers. In this case, they do it themselves.

3 INTEGRATING ARCHAEOLOGICAL AND LOCAL EPISTEMOLOGIES. A CASE STUDY OF THE LINAPACAN ISLAND (PALAWAN, PHILIPPINES)

Kowalczyk, Zuzanna (Adam Mickiewicz University, Poznan, Poland)

This paper aims to critically examine the disparities between Eurocentric ontologies and epistemologies, and local knowledge, specifically within the context of Linapacan Island in Palawan, Philippines. The research seeks to address the question of whose voice prevails in shaping narratives about the past and the mechanisms through which such narratives are constructed. By focusing on the interplay between Eurocentric and local epistemologies, the paper investigates the extent to which archaeological practices contribute to the dominance of certain voices and perspectives in historical discourse.

The Linapacan case study involves an archaeological survey and ethnographic research aimed at documenting the island's heritage. The research design intentionally incorporates both archaeological methods and local insights (recognized through anthropological investigations), and encourages a shift towards a more equitable and pluralistic approach in constructing narratives about the past, challenging traditional power dynamics in archaeological discourse. Moreover, this research prompts crucial questions and stimulates critical thinking about the role and responsibilities of archaeologists and ethnographers in actively shaping and influencing the discourse surrounding the past, emphasizing the need for a more reflexive and ethical engagement with diverse epistemologies.

4 HUNTING TALES: AN ETHNO-ARCHAEOLOGICAL STUDY OF BAYAKA SPEAR HUNTING

Milks, Annemieke (University of Reading, Department of Archaeology) - Lew-Levy, Sheina (Durham University, Department of Psychology) - Kiyabiya Ntamboudila, Francly (Faculté des Lettres, Arts, et Sciences Humaines, Marien Ngouabi University, Brazzaville, Republic of the Congo)

Ethnographic analogy remains a way to understand chronologically distant lifeways, including of Neanderthals who have always been more or less 'othered' in our narratives. The practice of connecting recent and contemporary foragers with Pleistocene humans also remains strong, including in related disciplines concerned with human evolutionary processes. It may be unrealistic to think we can fully uncouple archaeology from ethnographic analogies as doing so removes a key strategy for interpreting the material record. Meanwhile the theoretical foundations – including core assumptions about material culture and behaviours – would remain. When we engage with small-scale societies we connect with people who have skills and knowledge that we lack. Can it work to consider alternative ways of being to explore potential variability of past behaviours, avoiding cherry-picking examples to support a particular theory? What ethical concerns remain if we 'reframe' in this way?

In this talk, we use a case study of our research with BaYaka foragers (Republic of Congo), designed to better understand the interconnected processes of spear hunting and learning to hunt. We explore the benefits of working with people with requisite skills and experience to understand material culture (in this instance, spears) and behavioural processes (learning). Our research was designed to work with BaYaka adolescents and children, as well as adults, hoping to capture the voices and experiences of youngsters. We will discuss to what extent the research helps us understand the deep past, as well as the limits of inference.

5 OTHER[S]TORIES: DIGITAL ARCHAEOLOGICAL STORYTELLING AND ETHICAL CONSIDERATIONS

Sampatakou, Despoina (University of York)

Why do archaeologists tell stories? What stories do they tell, and why do they tell them? How ethical archaeological storytelling is? These and more are questions that I addressed in my recent PhD thesis research while exploring digital media for communicating archaeological research to the public. This paper aims to further explore and discuss some of the key findings of my research on interactive digital narratives and immersive technologies, as well as the ethics behind archaeological storytelling especially regarding issues such as the handling of human remains and decolonisation of crytpocolonised heritage.

The case study which is the foundation of the stories is Grave Circle A, a Bronze Age cemetery in Greece. Through archaeological storytelling based on osteobiography and archaeology of personhood, I created stories about the life and death of the individual MYCIV buried at the cemetery, as well as about Stamatakis, the archaeologist who excavated the cemetery in the 19th century along with Schliemann, and the reexamination of the skeletal remains in 21st century by Dr Nafplioti and her team. Through those stories, I also developed a methodology for evaluating similar DIY archaeological projects, aimed to put the researcher at the centre of the analysis and the storytelling, considering ethics around telling the stories of others who lived millennia ago.

6 ONLY A DISASTER NARRATIVE? HOW MEMORIES OF ENCOUNTERS WITH THE STOREGGA TSUNAMI MAY HAVE AFFECTED MESOLITHIC SOCIETIES

Nyland, Astrid (Museum of Archaeology, University of Stavanger)

It was initially natural scientists who recognised the Storegga tsunami which had wrecked the coastline of western Norway, Northern Britain, and Scotland, 8200 years ago. Based on the severity of assumed impact, researchers have suggested that this must have represented a disaster for the Stone Age population. Archaeologically, its impact is primarily studied via modelled C14 dates (inferring demographic impact), site location patterns (looking for changes or disturbances in settlement patterns), lithic technology, or trying to identify tsunami deposited layers directly on top of settlement sites. The story of the Storegga tsunami is hence mainly read from the top – down, from curves, graphs and hypothesis of major change – and the grand narrative is one of disaster, devastation, demographic collapse, and societal down turns. But are these stories the only one available? Are there stories about the day the sea turned Monster not yet told?

The material record from the event is indeed fragmented and non-conclusive. However, instead of seeing this as inhibiting, by considering storytelling and worlding of disaster and crisis as also part of a Mesolithic everyday life, other types of data and interpretation of these data, become relevant. Broadening knowledge of what represents a tsunami encounter, tsunami impact, or memories of crisis, gives new scientific knowledge. But where should those stories be told, should we keep to scientific journals, or is a children's book also a valid output from a large research project?

7 WHAT STORIES ARE (OR CAN BE) TOLD WITH ARCHAEOLOGICAL DATA?: EXPERIMENTS IN SITE PHOTO REUSE WITH DIFFERENT AUDIENCES

Perry, Sara (Museum of London Archaeology (MOLA)) - Simandiraki-Grimshaw, Anna (Museum of London Archaeology (MOLA))

Archaeologists create vast amounts of specialised data, yet these are often difficult to access and reuse, even for practitioners themselves. Reuse, in particular, is hindered by the fact that archaeological data progressively lose their complexity and nuance as they are gathered and structured in different recording and storage systems. Such systems regularly force us to strip our data of the meaning and dynamism needed to convey rich and complicated narratives about the past. This denuded data landscape severely disservices archaeologists. It excludes other professionals and policy makers from engaging with and being inspired by our work. Most problematically, it alienates local communities from the cultural heritage they may care about and from which they may wish to benefit.

Transforming Data Reuse in Archaeology (TETRARCHS: www.tetrarchs.org) is an international project dedicated to enriching archaeological data at all points in their life for more wide-ranging and expressive reuse. In this talk, we present the results of TETRARCHS' storytelling experiments with archaeological photographs from a long-excavated site in central London, England, conducted with nearly 100 people from distinct communities: archaeologists (representing a range of sub-specialities), creative practitioners, school children and others working or living near to the site. We demonstrate how these communities 'optimise' archaeological photos for storytelling; we discuss the commonalities and divergences between approaches taken by specialists and non-specialists in exerting imagination and creativity onto the data; and we reflect on the tropes and biases seemingly inherent in even the most mundane archaeological photographic records and picture-taking habits. Drawing on photographic and narrative theory, critical data studies, and participatory design, we argue for revising our basic approaches to data recording and data deposition with storytelling in mind, in order to realise more fertile, democratic and just interpretations of the past.

1057 THE MEDITERRANEAN IN SCANDINAVIA ? IMPORTS AND TRADE DURING THE MIDDLE AGES AND EARLY MODERN PERIOD, C. 1000-1800

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Haggren, Georg (University of Turku; University of Helsinki) - Kjellberg, Joakim (County museum of Uppland, Uppsala; The medieval museum, Stockholm) - Wennberg, Tom (Museum of Gothenburg)

Session format: Discussion session (with formal abstracts)

How were Scandinavian countries and the Baltic market connected with Mediterranean and Southern European regions over the previous thousand years? What are the material traces of these connections? Can these connections be viewed from archaeological remains, and what do these finds tell us of activity between the two regions?

Material culture will be the focus of this topic. This session seeks to investigate imported goods, trade and connections from the Mediterranean and Southern European region into the Scandinavian societies and the Baltic market. It endeavours to examine what was desired and what was used at Courts, churches and households in the North. We also seek to address the issue of status and discuss whether there are any differences between imports found in common and wealthy households? Are there changes in fashion or function that can be evidenced and used as explanations, can patterns be identified and did these patterns change over time?

Examples of Mediterranean goods found in Scandinavian contexts usually include pottery from Italian, Portuguese and Spanish kiln sites, glass from Venice, shoes made from cork from the Iberian Peninsula and olive, fig and grape seeds from soil deposits. What do these finds represent; do they imply status, diet, migration or new ways of living? Did these goods arrive directly, or did they come via secondary contacts (and from where, and when)? Lastly, what goods are missing from these contexts and how does this affect knowledge of these Mediterranean and Scandinavian connections?

ABSTRACTS

1 THE METROPOLE AND THE MEDITERRANEAN

Whatley, Stuart (Museum of Copenhagen) - Keenan, Samuel (Museum of Copenhagen)

From ca. 1000-1250 Copenhagen developed from a village or set of villages into a walled town, which by the mid 15th century became the capital of Denmark and seat of the Crown. By the 1600s, it had grown into the largest city in Denmark and Scandinavia, undertaking global trade as a Metropole. Through this process, many foreigners in the form of merchants, sailors, architects and the clergy moved to Copenhagen, creating a multi-cultural population centred on the town square and the harbourside.

Although recent research has focused on the role of the city's Dutch and German inhabitants and their material culture, little has been studied on the Mediterranean connections and their part in transforming the city. From the 15th to the 17th century, artefacts in new ceramic and glass forms from Spain and Italy are found in Copenhagen, indicating a transformation in the preparation and cooking of food, and new dining styles, a process viewed over Northwestern Europe. These were found alongside Mediterranean foodstuffs and liquids that over time would become a common site on Danish tables and part of the everyday diet. New ceramic forms were also utilised (olive jars) alongside older types such as amphorae in the transport of liquids.

This talk will focus on what was transported, what was used and by whom, and where the artefacts were retrieved from, to understand the effect of the Mediterranean trade on Copenhagen lifestyles.

2 GOTHENBURG AND THE MEDITERRANEAN - TRACES OF TRADE ROUTES

Wennberg, Tom (Museum of Gothenburg)

Gothenburg was the main Swedish port to the west during the Early Modern times. The city where founded 1621 by king Gustavus Adolphus of Sweden with the specific purpose to be a part of the global trade of the time. Gothenburg played a peripheral role in this system of trade routes during the 17th century though. There are, however, both written and archaeological evidence of the world trade strongly influencing the inhabitants of Gothenburg. Tobacco, exotic spices, and ceramics are typical finds that give evidence for this long-distance trade.

One of the centers of trade with connection to the Mediterranean was Lisbon. The importance of this specific connection has recently become apparent in the archaeological source material. The evidence for trade routes into the Mediterranean Sea is scarcer. Though we know of these connections, the archaeological finds with a Mediterranean provenance are very few. This presentation will the archaeological evidence and discuss possible reasons for this skewed picture.

3 MEDITERRANEAN GLASS IN THE NORTH - ANALYZING A LONG TRADITION SPANNING CENTURIES

Haggren, Georg (University of Turku; University of Helsinki)

Small numbers of Mediterranean vessel glass was imported to Scandinavia already during the Roman, the Merovingian and the Carolingian Era. Vikings are known of their raids but they were also tradesmen uniting European markets. Vikings were no uncommon visitors in Constantinople, and these connections continued through the era of crusades. As a result, for example some enameled Byzantine glass beakers were introduced to early Scandinavian towns.

In the early second millennium there were three alternative routes from Scandinavia to the Mediterranean and back. The first one was the hazardous western route along the Atlantic coast, the second possibility was based on land routes through the European continent and over the Alps, while the third one followed eastern river routes from the Baltic to the Black Sea. This route was closed for good in the 1240s when the Mongols conquered vast Eastern European areas.

Glass researchers noticed already in the early 20th an exclusive 13th to 14th century group of enameled beakers. C. L. Lamm identified them first Eastern Mediterranean calling them Syro-Frankish but later on they have been shown to be products of Venetian workshops. These beakers were distributed literally over whole of Europe, including Scandinavia.

During the 15th century glass exports from the Mediterranean ceased temporarily. The demand of the exclusive products of Italian workshops increased again in the 16th century. This time several skilled workers migrated closer to their markets too. Glass houses producing vessels à la façon de Venise were founded in several cities north of the Alps. In the end, a couple of such factories were located in Denmark and Sweden too.

How should we interpret the trade of Mediterranean vessel glass that continued over centuries? Why were the skills and the production transported to north at the end? How did this process take place?

4 WHO USED VENETIAN ENAMELLED GLASS BEAKERS IN CENTRAL SWEDEN? - RECENT FINDS AND NEW UNDERSTANDINGS

Kjellberg, Joakim (Medeltidsmuseet/Upplandsmuseet)

Finds of venetian enamelled glass drinking vessels – often referred to as Aldrevandin beakers after its most famous example in the British museum – have appeared among the artefact assemblages from several recent excavations in Sweden. The finds that will be discussed in this paper comes from Stockholm as well as Uppsala, Old Uppsala and Enköping in the province of Uppland in central and eastern Sweden.

The shards from Stockholm, Uppsala and Enköping come from 13th and 14th century urban household deposits. The sherd from Old Uppsala comes from a building in a more rural setting, interpreted as part of the archbishops manor in the 13th century. The new finds thus complete and partly challenge the previously interpreted narrative of a very

exclusive category of glass only present in the most high-status places, such as the previous finds from the royal castle in Stockholm. The paper will focus on the geographical, chronological and social contexts of the finds.

1058 DRYLAND AGRICULTURE AND LAND USE; PAST, PRESENT AND FUTURE RESILIENCE

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Whitehouse, Nicki (University of Glasgow) - Fiorentino, Girolamo (University of Salento)

Session format: Discussion session (with formal abstracts)

Drylands provide a vital but sometimes overlooked land resource, ranging from forests and other wooded lands through to grasslands and deserts. They have been inhabited for thousands of years and are home to societies that display a range of adaptive behaviours. The current climate crisis is putting livelihood in drylands at risk, as climate and environmental changes are having a magnified impact on these ecosystems and the societies that inhabit them. Up to now, traditional and long-term agricultural and ecological knowledge has been largely under-explored in these regions, despite the challenges facing these areas today and the richness of information to be gained.

At the same time, we believe the rest of the world can learn from drylands: agricultural systems have typically developed in areas of more limited natural resources (e.g., rainfall, soil fertility), demanding and changing climatic contexts, and sometimes challenging socio-political systems, but are also based on crops that can be grown in a wide range of ecological niches. Communities have often transformed soils and adapted land use to maximise opportunities for crop growing in the face of aridity (e.g., cultivation terraces) and scarce resources. Similarly, the integration of farming with livestock and wild resources is often key to achieve food security in drylands. The resilience of dryland systems may therefore offer important lessons for more northern latitudes whilst knowledge of traditional and ancient land and farming adaptations also offer important understanding and solutions for drylands themselves.

In this session we would like to focus on the archaeology of dryland agriculture and land use (broadly defined), with a particular emphasis on case studies from the Mediterranean, South-west Asia, South and Central Asia and dryland Africa. This session draws its inspiration from a recently funded Marie Curie Doctoral Training Network [AGRI-DRY] with a focus on this topic.

ABSTRACTS

1 AGRI-DRY: DRYLAND AGRICULTURE AND LAND USE; PAST, PRESENT AND FUTURE RESILIENCE

Whitehouse, Nicki (Archaeology, University of Glasgow, UK) - Madella, Marco (Complexity and Socio-Ecological Dynamics (CaSEs), Research Group, Universitat Pompeu Fabra, Barcelona, Spain) - Fiorentino, Girolamo (Department of Cultural Heritage, Università del Salento, Italy) - Mothulatsipi, Sarah (Archaeology Unit, Dept History, University of Botswana, Botswana) - Ordonez, Alejandro (Department of Biology: Centre for Biodiversity Dynamics in a Changing World, University of Aarhus, Denmark) - Schoeman, Alex (School of Geography, Archaeology & Environmental Studies, University of Witwatersrand, Johannesburg, South Africa)

Drylands have been inhabited for thousands of years and are home to societies that display a range of adaptive behaviours; these practices are underpinned by Traditional Ecological Knowledge. Drylands are especially vulnerable to climate change, shifts in precipitation patterns, increasing desertification, and extreme events, whilst inappropriate soil management practices have led to major land use changes and soil degradation. These factors hinder the ability of communities to produce food, and negatively influence their ways of life and well-being. Future climate change will continue to severely impact these ecosystems and communities and there is a critical need to understand how to produce food more sustainably.

Long-term perspectives on how and why agricultural systems have emerged and developed in the light of evolving needs and changing environmental conditions offer a way of understanding how people developed and interacted sustainably with their environment. Combined traditional and ancient agricultural practices provide more than a historical perspective: they offer solutions to the challenges posed by the need to grow food within a warming world. At the same time, the rest of the world can learn from drylands: agricultural systems have typically developed in areas of more limited natural resources (e.g., rainfall, soil fertility), demanding and changing climatic contexts, but also have used novel and diverse crops that can be grown in a wide range of ecological niches.

We focus on a recently funded EU Marie Curie DN and UKRI project, AGRI-DRY, which uses the Mediterranean Basin, North Africa & Sahara, and Southern Africa as the main geographic foci and outline case studies that highlight key crops, farming and land use strategies that we believe were critical to a resilient system.

2 LONG-TERM TRENDS IN ECOSYSTEM AND AGRICULTURAL BIODIVERSITY IN NEOLITHIC WEST ASIA

Roe, Joe (University of Bern)

We now understand that biodiversity is critical to maintaining life-supporting ecological processes. Agriculture is typically associated with significant loss of biodiversity: globally, as has become all too evident in the last few centuries; but also in drylands specifically, which are frequently considered under threat from rangeland degradation and 'desertification'. It is perhaps surprising, then, that the world's earliest agricultural systems—which can be traced to West Asia at the beginning of the Holocene (c. 11,500 BP)—emerged within dryland ecologies characterised by relatively low biodiversity and high ecological instability. These are ecosystems that are thought to be particularly susceptible to climatic and anthropogenic disturbance, yet they are also where we see our species' first experiments in large-scale ecological intervention. Though several potential solutions to this paradox have been presented, far less attention has been paid to verifying the premise: was early agriculture actually associated with a loss in biodiversity?

This paper represents a first attempt to trace the long-term evolution of biodiversity in early agricultural systems in West Asia using computational methods. Potential biodiversity of the plant community is modelled using stacked species distribution models and palaeoclimatic reconstructions. Observed biodiversity of the agricultural system is measured in the taxonomic composition of a large dataset of 240 distinct archaeobotanical assemblages from 135 Neolithic sites across the region. Contrasting these two independent signatures of biodiversity reveals a complex association between ecosystem and agricultural biodiversity in the first farming societies. It also questions the assumption that agriculture necessarily leads to a loss of biodiversity, or that it has always done so.

3 THE BOOM AND BUST OF DESERT AGRICULTURE: ARABLE TRANSFORMATION OF THE COUDE DE DRAA, MOROCCO UNDER MUSLIM RULE

Pelling, Ruth (UCL (University College London); Historic England) - Fenwick, Corisande (UCL) - Bokbot, Youssef (INSAP) - Mattingly, David (University of Leicester)

Long term sustainability of arable agriculture in deserts is by necessity reliant on water, manure and appropriate crop choice, while economic expansion beyond subsistence requires significant investment. Such landscapes are vulnerable, reliant on both politics and economic markets as well as the fragility of non-renewable resources. The emergence of Saharan trading networks associated with new Islamic states in North Africa (8th-10th centuries) and the great medieval empires of the Almoravids and Almohads (11th-13th centuries) is associated with the development of successful specialist farming landscapes across Morocco. Until recently the archaeological focus has tended to be on the urban and trading centres and the crops produced rather than the farming communities. A number of recent projects are attempting to re-focus on the arable practice as well as the lives of farmers. The Moroccan-British Oas-Civ project (INSAP, Uni of Leicester and UCL; Fenwick et al. 2021; Mattingly et al 2017), has been surveying and excavating sites within a well-preserved farming landscape with hundreds of settlements and extensive networks of irrigated cultivation plots in the desert of the Coude de Draa, south eastern Morocco. The earliest traces of occupation and associated cereal cultivation date from the centuries immediately prior to Muslim rule, apparently extending and flourishing during the medieval period, before ultimately failing by the 19th century. As part of the associated EVERYDAYISLAM Project (UCL) this paper will trace the changing character, timing and impact of arable farming in the Coude de Draa following the arrival and expansion of Muslim rule. While the presentation will focus on the survey results, and provisional archaeobotanical evidence from the first three seasons of excavation, it will also consider the potential of other analytical techniques for understanding arable change in this environment.

Fenwick et al (2021) <https://doi.org/10.1558/jia.20440>

Mattingly et al (2017). <https://doi.org/10.1163/21915784-12340009>.

1060 FEMINIST PERSPECTIVES ON SOCIAL ARCHAEOLOGY. AGE SESSION IN MEMORIAM LIV HELGA DOMMASNES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Monton-Subias, Sandra (ICREA; Pompeu Fabra University) - Fries, Jana Esther (Lower Saxony State Institute for Cultural Heritage) - Palıncaş, Nona (Vasile Pârvan Institute of Archaeology, Romanian Academy) - Wicker, Nancy (The University of Mississippi, Department of Art & Art History) - Doris Gutmiedl-Schumann, Doris (University of the Bundeswehr Munich, Historical Institute)

Session format: Regular session

Archaeology provides important tools to study past societies. Past people from all parts of societies left behind material remains. Archaeology can therefore shed light on the living conditions of marginalized groups. This has been one of the main topics in feminist archaeology from the very beginning. But feminist archaeology does not only explore

the past; it also considers present-day societies regarding the relationship between archaeological discourse and contemporary cultural logics, the role of archaeology for the general public, or the rationale and working conditions within archaeological institutions.

This session, sponsored by the Archaeology and Gender in Europe (AGE) network, will acknowledge and celebrate the pioneering and fundamental investigations that Professor Liv Helga Dommasnes (1949-2023) contributed to feminist archaeology and archaeology in general through discussion of: a) feminist perspectives on social archaeology, and b) feminist archaeology for an equitable future.

Contributions dealing with current concerns in feminist archaeology will be welcome, encompassing, but not limited to, the following topics:

Feminist analytical frameworks, concepts and interpretations of social dynamics

The development of feminist analyses of archaeological discourse

Re-conceptualization of the past and its communication to the general public

Decolonial/de-patriarchal perspectives

Feminism and archaeological institutions

Networking and collaborative work in feminist archaeology

Feminist archaeology and queer archaeology: marriage or divorce?

Feminist archaeology for a non-patriarchal present and future

Non-Western feminist perspectives and their relevance for archaeology

The future of feminist archaeology: where are we going now?

ABSTRACTS

1 RECALLING LIV HELGA'S INITIAL WORKS ON WOMEN AND FEMINISM

Hjorungdal, Tove (Department of archaeology and ancient culture)

Liv Helga Dommasnes (1949-2023) was the very first Norwegian archaeologist to situate archaeology and interpretations of the past in a feminist position. As her first works are written in Norwegian, and thus less known, it is of importance to be aware of their early appearance and their importance to further development of gender and feminism in Scandinavian archaeology. Her first work, her master artium thesis (1976) dealt with Viking Age burials in western Norway. Tools of analysis were inspired by social anthropology, Peggy Sanday's method of division of work by gender, together with Binford's social persona with reference in quality and quantity of burial equipment. Important results were the visibility of women in Viking age Western Norway, by their rich dress outfit, together with textile equipment, a variety of tools, and west European imports. Conclusion: women were in charge of the farms when male partners were out trading and raiding.

Still more important is that Liv Helga, who earned a degree in philosophy, initiated an analysis of archaeology as a part of western patriarchal traditions in society and academia. This was first published in Norwegian journal KAN (Women in Archaeology in Norway), of which she was one of the editors, from 1985 on. Liv Helga published a program for women's studies in archaeology. Feminist analyses were made as well of the heritage discourse in Norway.

Later, she published a popular book in Norwegian on West Norwegian archaeology. The background of the book was her decades of curatorial and academic work in the regions around the Historical Museum in Bergen. The book had an intersectional and multispecies approach to prehistory.

2 WHO CARES? MOVING BEYOND NARRATIVES OF WAR OR ECONOMY IN LATER MEDIEVAL ARCHAEOLOGY

Dempsey, Karen (Cardiff University)

Decades of gender and feminist archaeologies have highlighted that caring activities are not foregrounded in archaeological narratives despite their pivotal roles in maintaining society. Yet, the practices of care are articulated in particular ways that leave material traces. For the later medieval period in Britain and Ireland, much indirect evidence survives as evidenced through spatial arrangement of buildings, mortuary contexts, placed deposits and living plants preservation. The work of early gender archaeologists, their feminist perspectives and social approaches have enabled researchers to address new questions outside of the traditional narratives of power, economy or status. What can we now say about gendered aspects of the material practices of medieval care? In this paper, we will explore daily life in medieval castles through the lens of 'care', upending traditional narratives that elevate militaristic function at the expense of understanding lived and gendered experiences. These alternative stories embrace archaeological ambiguity

and highlight the full sensorium of daily life as well as the entangled emotional experiences of medieval people. In doing so, it shows the power - theoretically and methodologically - of centring care in our archaeological narratives.

3 A FEMINIST ARCHAEOLOGY FOR EARLY COLONIAL GLOBALIZATION (AND FOR OUR PRESENT)

Monton-Subias, Sandra (Universitat Pompeu Fabra)

In this paper, I will discuss the latest theoretical foundations that define the feminist approach of maintenance activities. The analytical approach of maintenance activities was collectively born within a group of Spanish feminist archaeologists to highlight the structural role of a set of routine tasks of everyday living indispensable to create and sustain life, and the values, attitudes, capacities, behaviours, and social dynamics required and promoted by them. Human beings cannot survive in a healthy fashion in their absence because they make human life possible. By foregrounding cooperation, interdependence, social bonding, cultural continuity, affective capacity, empathy and care as fundamental to social life, this approach offers different interpretations of the past because dynamics that usually remain unseen are "reinserted" into history as central.

I will use the example of early colonial globalization to illustrate how maintenance activities, and their material culture, were both important in shaping and resisting this phenomenon. This example will also serve to discuss how new paradigms to interpret the past emerge when focus shifts away from the patriarchal cultural logic that dominates this interpretation.

4 EXPLORING ARCHAEOLOGICAL INTERPRETATIONS: REINFORCING STEREOTYPES OR DECONSTRUCTING SOCIAL CONSTRUCTS? INSIGHTS FROM HUNTER-GATHERER SOCIETIES AT CZECH PALEOLITHIC SITES

Lecbychová, Olga (Institute of Archaeology of the Czech Academy of Sciences, Brno) - Matulová, Klára (Institute of Archaeology of the Czech Academy of Sciences, Brno)

In recent decades, Western society has faced the redefinition of gender roles, with some fearing that the deconstruction of traditional social norms would lead to the loss of the 'good old (patriarchal) world' based on a binary concept of biological sexes merging with gender and their rigid social roles.

Challenging stereotypes is part of a reflexive approach applied in various social science disciplines today, emphasising not the replacement of one stereotype with another, but rather a focus on constant openness to different perspectives and understanding their contextuality. Gender archaeology has shown that, despite the use of the precise methods of the natural sciences in archaeology, our reconstructions of past societies have been unconsciously shaped by the social patterns of contemporary society.

This contribution deals with mapping interpretations of the social structures of hunter-gatherer cultures and their visual presentations, with particular reference to archaeological research in the Czech Republic, and explores the social impact and responsibility of archaeology in shaping current social norms. Archaeology demonstrates that it is possible to reconstruct gender arrangements more freely and that patriarchy is a product of historical evolution rather than grounded in biology.

5 ASEXUAL FIGURINES OR NEOLITHIC DEITIES? THE CASE OF CUCCURRU S'ARRIU (SARDINIA)

Carta, Arianna (University of Primorska)

Archaeological narratives about gender have concerned not only "flesh-and-blood" bodies but also their most direct representations: figurines. In this contribution I will attempt to show how archaeological theories and interpretations have shaped women's prehistory by mystifying or erasing female gender, both in processual and post-processual archaeological theories. On the one hand, until the 90s, the deceased in graves with significant finds have often been assigned male gender, and figurines have been often considered Mother Goddesses without any serious inquiry. With post-processual theories the main trend has been to define the figurines as "asexual", thus erasing female gender and excluding women from the main narrative. In the attempt to show the consequences of these (mis)interpretations, I will discuss the case of a Sardinian Neolithic's statuette, with such iconographic features that it was used as the cover of *The Oxford Handbook of Neolithic Europe* (2019). This figurine has been found in the Cuccurru S'Arriu's Neolithic burial (tomb #386) and it is dated ca. the first half of V millennia BC, located in Cabras (Sardinia).

Through an interdisciplinary iconographic and comparative analysis, I will try to show how this figurine could have been a goddess. In addition, I will argue that the female body narrative, within archaeological theories, has apparently changed in order not to change (i.e. add gender and stir), as Tomasi di Lampedusa's words featured in EAA's motto 2024: "If we want that everything remains the same, it is necessary that everything changes." G. Tomasi di Lampedusa (1896-1957) - *The Leopard*..

6 TOWARD AN INTERSECTIONAL ARCHAEOLOGY: CHALLENGING NEOLITHIC FUNERARY CONTEXTS

Morell-Rovira, Berta (ArchaeologyHub.CSIC; IMF-CSIC) - Díaz-Zorita Bonilla, Marta (Archaeometry Research Group, Institute for Pre- and Protohistory and Medieval Archaeology, Eberhard Karls Universität Tübingen) - Gibaja Bao, Juan F. (IMF-CSIC) - Masclans, Alba (Independent researcher)

This communication presents a series of case studies delving into diverse Neolithic funerary contexts across Central Europe and the Western Mediterranean. Employing a multi-proxy approach, the research integrates diverse bioarchaeological analyses, including mobility and dietary isotopes, ¹⁴C dating, grave good and use-wear analysis of lithic tools. These case studies challenge the conventional biological-sex dichotomy, revealing a nuanced variability in the archaeological record and emphasising the necessity for a more refined theoretical framework to address this complexity.

The research actively promotes an intersectional perspective, exploring how multiple social categories intersect to shape past funerary practices. In this context, intersectionality recognizes the interconnected nature of social categories, emphasizing the interweaving of various aspects of identity. These include, but are not limited to, gender, age, ethnicity, social class, sexuality, individual abilities, among others

Participation in this session is envisioned as an opportunity for exchanging ideas and methodologies, addressing doubts, and collectively developing a more robust and inclusive approach to interpreting archaeological records. Through this presentation, we would like to contribute to the significance of intersectional perspective in archaeological research, emphasising its relevance for achieving a more accurate and comprehensive understanding of the social dynamics within past communities.

7 SCIENCE AND THE INTERPRETATION OF PREHISTORIC SOCIAL DYNAMICS: THE MEMORIES PROJECT AS A CONTRIBUTION TO FEMINIST ARCHAEOLOGY

Cintas Peña, Marta (University of Seville) - Lucíañez Triviño, Miriam (University of Seville) - Herrero-Corral, Ana (Austrian Archaeological Institute, Austrian Academy of Sciences) - Rebay-Salisbury, Katharina (University of Vienna; Austrian Archaeological Institute, Austrian Academy of Sciences) - Fuentes Porto, Alba (University of La Laguna) - Kanz, Fabian (Medical University of Vienna) - Montero Artús, Raquel (University of Seville)

Thanks to the impetus of the feminist movement, research has undergone a profound transformation in recent decades. The change is particularly visible in the field of archaeology, where many researchers, including Liv Helga Domasnes, have shed light on the invisible, normative as well as exceptional women. This has contributed to the creation of a collective memory in which not only men, but also women and children are represented.

Cutting-edge techniques have opened up new possibilities for reconstructing the biographies of prehistoric women in the absence of written records. Their application has allowed us to bring to light some unique women (such as the "Ivory Lady" of the Chalcolithic site of Valencina) who had previously been identified as men. This in turn requires us to rethink traditional models of social complexity on the one hand, and the relationship between gender and power on the other.

This contribution outlines the MEMORIES project (Memoria de Mujeres. Recuperando Identidades Singulares en la Prehistoria) and presents its first results. The main objective of the project is to deepen this line of research through the study of exceptional funerary contexts, such as the artificial cave of La Molina (Seville). At this site, the remains of an adult female were found, together with an exceptional set of grave goods, which remind us of the burial of the 'Ivory Lady'.

We will discuss how building a new science-based analytical and conceptual framework to interpret social dynamics in prehistory will contribute to the future of feminist archaeology.

8 LEARNING FROM NON-EUROPEAN PERSPECTIVES ON GENDER TO BETTER UNDERSTAND WOMEN IN EUROPEAN PREHISTORY

Palincas, Nona (Vasile Pârvan Institute of Archaeology, Romanian Academy)

It is widely recognized that European feminist archaeology - as well as European gender archaeology more broadly -, at least when it focuses on past societies from the regions that are presently part of the Western countries, continues to be dominated by what we generally call Western perspectives on gender - i.e. perspectives rooted primarily in Western sociology and contemporary Western social experiences, legal and political debates. At the same time, European studies on gender in archaeology have also recognized the value of non-European perspectives, particularly those based on critical social theory and ethnographic and anthropological fieldwork as important sources of inspiration for new ways of thinking about gender. Considering that there is still plenty of room for learning from non-European/non-Western perspectives, this paper will look at sociological, anthropological and archaeological work made

in Africa, the Americas and parts of Asia in search for new ideas and then revisit a few case studies from the Eastern European Bronze and Early Iron Ages to see how they could be interpreted differently. The focus will be on women's statuses and roles in prehistoric societies.

9 GENDERED SPACES AT WAH-SUT: THE FICTIONAL TALE OF PRINCESS RENISENEB THROUGH AN ARCHAEOLOGICAL LENS

Crawford, Courtney (American University in Cairo)

Gender archaeology has created new ideas and concepts for interpreting archaeological material. In Egyptology, the topic of women and gender studies has become more popular in recent years but the attempt to gender spaces through fictional storytelling has yet to take off in the field. One site in particular, Wah-Sut, contained many artifacts that pertain to women that can illuminate their role and their spaces in ancient Egypt. Additionally, most archaeology work is only analyzed by an academic audience, which does not allow the general public to learn more about the past. Feminist archaeologist, Janet Spector, wrote a fictional story based on archaeological material and historical texts of an artifact only used by women to allow both academics and non-academics to understand the past better. Although her research focuses on North American Archaeology, it highlights the importance of archaeological storytelling and how it can help a larger audience understand the ancient world. This author creates a fictional story about Princess Reniseneb by using archaeological evidence that was found in a palace at the site of Wah-Sut to contextualize the artifacts found as well as create a story that can attract a larger audience to the study of women in ancient Egypt.

10 LOOKING AT ARCHAEOLOGICAL EVIDENCE OF CHILDHOOD: A DIACHRONIC REVIEW OF OBJECTS, SOCIALIZATION PRACTICES AND ENVIRONMENTS IN PAST SOCIETIES

Romagnoli, Francesca (Universidad Autónoma de Madrid) - Comino Comino, Alba (Universidade Nova de Lisboa) - García-Basanta, Andrea (Universidad Autónoma de Madrid) - Prados Torreira, Lourdes (Universidad Autónoma de Madrid)

The Archaeology of Childhood is focused on the study of the youngest individuals, their needs, activities, and living and playing spaces. The study of childhood is also strongly interested in understanding the relationships that children maintain within their social group, both within their age group and with adults, and look at childhood as a key period not only in the personal development of an individual but also because it is the period in which individuals are acquiring skills and knowledge and are being integrated into the community. The discipline developed in the last few years influenced by Feminist Archaeology that drew attention to the social aspects in the past and stressed the invisibility of several social and age groups, including childhood, both in archaeological research and the socialisation of knowledge. Furthermore, the feminist perspective highlighted as age categories and roles are culturally defined. Thus, they are not always and everywhere the same and are not directly linked to biological features: childhood is a social and cultural phenomenon since prehistoric times. In this paper the authors present the current approaches in the Archaeology of Childhood, discuss the biases and constraints that still limit the development of this discipline, and provide an overview of the archaeological knowledge on childhood in different periods and cultural contexts in the past.

11 COFFEE WITH ELAGABALUS: TRANSGENDER ARCHAEOLOGY FOR A BETTER FUTURE

Jaffe, Gali (Freelance Lecturer/Researcher)

In the past few years, we are witnessing an escalation in transphobic attacks across all types of communication forms, from books, to written journalism, to websites, internet news outlets, and especially social media.

These attacks are based on misinformation, as well as a fear of change and alternative lifestyles. The main accusation of recent times is that the whole idea of transgender people is new, and as I will lay out in my talk, this notion is absurd beyond all measure.

In depth current archaeological research proves the existence of transgender and queer people for at least the last five thousand years. This is manifested in many various archaeological finds. There is evidence of priests changing their gender to serve a specific goddess, there are graves which show male skeletons with female grave goods, or female skeletons with male grave goods (including weapons), contemporary written sources attesting to the existence of transgender monks and much more.

As a trans woman and archaeologist, I believe that by using this knowledge and spreading this information widely, we can affect a change in the way transgender people today are being treated, and maybe even change and eradicate the myth that "Transgender people are a new idea".

In my lecture I will show how we can use these archaeological finds of the past together with modern new media tools, such as social media sites, to inform a wide audience about the existence of transgender people in the ancient past. By combining the finds and the internet to inform the people of the present and the future, we can change the narra-

tive which is being utilised now against transgender people, and maybe in this way, help make the lives of transgender people, and future society in general, better ones.

12 FEMINIST ARCHAEOLOGY AND QUEER ARCHAEOLOGY: DIVORCE OR FAMILY COUNSELING?

Eklund, Anna (Department of Archeology and Ancient History, Uppsala university)

There is no shortage of theoretical perspectives introduced within archaeology, and the same applies within gender archaeology, in which queer and intersectionality are two of the latest newcomers. Archaeology's enthusiasm for embracing new – often not so new – theoretical approaches from other scientific disciplines are well known and debated. Once in every decade another revolutionary theory is introduced and embraced, a period of infatuation occurs and all is well for a while. However, soon the feeling of novelty passes and the limitations and incompatible elements become visible, and this is where it goes wrong. Instead of putting in the effort of improving and developing the theory further, another, supposedly better fitted theoretical approach is adopted, and so it continues. The previous theoretical approach is now considered out of fashion and not to be discussed further. Maybe now is the time to refrain from the usual divorce procedure and instead engage in family counseling? I suggest that gender archaeology abandon this adopt-and-discard attitude towards theoretical frameworks and start to engage more deeply in the development of theoretical approaches, both old and new. In this way, we can create theoretical frameworks that contribute to new archaeological knowledge, and, ideally, perhaps even contribute to knowledge development in other disciplines.

1061 APPRECIATING THE ARCHAEOLOGICAL VALUE OF PRESERVED FAECES USING MULTIFACETED METHODS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Green, Eleanor (BioArCh, University of York) - Fuks, Daniel (Ben-Gurion University of the Negev; McDonald Institute for Archaeological Research, University of Cambridge) - Dunseth, Zachary (Archaeology Program, Boston University)

Session format: Regular session

Ancient feces are a valuable type of archaeological material and intact dung, or coprolites, provide a micro-context which serves as time capsules of past ecologies and economies. Preserved dung is being increasingly investigated through an expanding range of archaeological science techniques. Among them, geoarchaeological (micromorphological, mineralogical), archaeobotanical (palynological, carpological, phytolith), parasitological, spectroscopic (Raman, NIR, FTIR) and biomolecular (genomic, proteomic, lipidomic, isotopic (^{14}C , $\delta^{13}\text{C}$, $\delta^{15}\text{N}$)) methods are being employed to reconstruct archaeo-faunal diets and microbiomes. The relative rarity of coprolites and the multidisciplinary nature of their study means there is little opportunity for like-minded researchers to connect formally. So, building on the community success of the coprolite session at the EAA 2023 Belfast, this session will provide a space to bring together dispersed researchers working on, and interested in, this special archaeological material. All archaeological fecal-related research will be considered, and we are particularly interested in multiproxy studies or those which advance the application of archaeological science techniques to intact coprolites.

ABSTRACTS

1 FODDERING STRATEGIES AND VEGETATION EXPLOITATION THROUGH THE MULTIPROXY STUDY OF HERBIVORE DUNG FROM MIDDLE BRONZE AGE N-ITALIAN SETTLEMENTS

Dal Corso, Marta (Department of Geosciences, University of Padova) - D'Aquino, Silvia (Dipartimento dei Beni Culturali, Università di Padova) - Piazzalunga, Giorgio (Dipartimento dei Beni Culturali, Università di Padova) - Baldan, Maela (Department of Geosciences, University of Padova) - Bortolini, Mara (Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice) - Battistel, Dario (Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice) - Manfrin, Maria Sofia (PrEcLab – Laboratorio di Preistoria, Protostoria ed Ecologia Preistorica del Dipartimento di Beni Culturali e Ambientali, Università degli Studi di Milano) - Gillis, Rosalind (Deutsches Archaeologisches Institut, Referat Naturwissenschaften, Berlin) - Polisca, Federico (Department of Geosciences, University of Padova) - Nicosia, Cristiano (Department of Geosciences, University of Padova)

During recent excavations at two Middle Bronze Age (MBA, ca. 1650-1350 BCE) settlements in northern Italy, particular attention has been given to the extrapolation of data from archaeological stratigraphy to understand past lifeways. Usually, cultural layers in sites inhabited by early farming societies are enriched in organic material that largely derives from dejections of humans and animals, besides other routine activities. Rarely, however, in-situ stabling layers have been identified as such in the stratigraphy and thoroughly analysed. In this presentation we will discuss

the investigation of MBA stabling layers at two sites south of Verona, with radically different preservation conditions: the waterlogged settlement of Oppeano and the site of La Muraiola di Povegliano, located in a well-drained area. In both contexts stabling layers composed of herbivore dung and litter have been exposed. At Oppeano, these deposits are found as finely laminated accretions, alternated to ash, inside perfectly preserved wooden “byre-houses”. At La Muraiola, instead, remains of similar stabling areas occur as calcium phosphate crusts. In the framework of the ERC CoG project GEODAP (Geoarchaeology of Daily Practices), we applied a multidisciplinary approach that includes soil micromorphology, botanical micro- and macro-remains and organic geochemistry to the study of stabling layers. Here we will focus on the palynological, carpological, anthraco-/xylo-logical and parasitological records to reconstruct foddering practices and environmental exploitation related to herding. Results are compared with other available datasets, which include GC-MS analysis and the faunal assemblage of livestock from the sites. A variety of different natural environments, partly disappeared, will emerge and seasonality of foddering practices will be discussed, leading ultimately to a better understanding of the lifeways of MBA communities in the Po Plain.

2 UNPICKING THE CONTENTS OF VIKING-AGE LATRINES PRIMARILY USING ANCIENT DNA METHODOLOGIES

Green, Eleanor (University of York)

Faecal concretions are amorphous masses of cemented material which, under favourable conditions, form via phosphatization in cesspits. Their potential biomolecular content is most similar to archaeological sediment. In this project, faecal concretions from Coppergate, York, UK, were analysed using a range of bioarchaeological techniques, including archaeogenetics, palaeoproteomics, lipidomics and microscopy. Results from ancient metagenomic analysis demonstrate that these samples contain a plethora of ancient DNA relating to the human diet, human waste and the local environment. Unlike coprolites (distinct faecal samples), the concretions give a mixed host DNA signature. Nevertheless, we hypothesised that these samples were likely to be human-derived given that they were found in formal waste pits. The human contribution to the cess was confirmed using CoproID and a hybridization capture of 1240k SNPs was performed, resulting in six of the ten concretions covering over 10,000 ancestrally informative SNP positions. Using a tool developed for forensic crime scene investigations, a minimum number of human contributors to the concretion's genetic profile was established. With further development, the analysis of concreted masses could present a new bioarchaeological opportunity to assess health, subsistence and environment at a community level.

Note, this work was completed with collaborators who will be acknowledged throughout.

3 DETECTION OF FAECAL MATTER IN A NEOLITHIC COMBUSTION FEATURE AT ABRIC DEL XICOTÓ (SPAIN) THROUGH A MULTIPROXY GEOARCHAEOLOGICAL ANALYSIS

Fernández-Palacios, Enrique (Archaeological Micromorphology and Biomarkers Laboratory (AMBI Lab), Instituto Universitario de Bio-Orgánica “Antonio González”, Universidad de La Laguna, 38206, Tenerife, Spain; Departamento de Geografía e Historia, UDI Prehistoria, Arqueología e Historia Antigua, Facultad de Humanidades, Universidad de La Laguna, 38206, Tenerife, Spain) - Égüez, Natalia (Archaeological Micromorphology and Biomarkers Laboratory (AMBI Lab), Instituto Universitario de Bio-Orgánica “Antonio González”, Universidad de La Laguna, 38206, Tenerife, Spain; Departamento de Geografía e Historia, UDI Prehistoria, Arqueología e Historia Antigua, Facultad de Humanidades, Universidad de La Laguna, 38206, Tenerife, Spain) - González-Olivares, Cynthia (SERP (Seminari d'Estudis i Recerques Prehistòriques), Universitat de Barcelona, 08001, Barcelona, Spain; Institut d'Arqueologia de la Universitat de Barcelona), Universitat de Barcelona, 08001, Barcelona, Spain) - Herrera-Herrera, Antonio (Archaeological Micromorphology and Biomarkers Laboratory (AMBI Lab), Instituto Universitario de Bio-Orgánica “Antonio González”, Universidad de La Laguna, 38206, Tenerife, Spain; Departamento de Química, Facultad de Ciencias, Universidad de La Laguna, 38206, Tenerife, Spain) - Mallol, Carolina (Archaeological Micromorphology and Biomarkers Laboratory (AMBI Lab), Instituto Universitario de Bio-Orgánica “Antonio González”, Universidad de La Laguna, 38206, Tenerife, Spain; Departamento de Geografía e Historia, UDI Prehistoria, Arqueología e Historia Antigua, Facultad de Humanidades, Universidad de La Laguna, 38206, Tenerife, Spain) - Mangado, Xavier (SERP (Seminari d'Estudis i Recerques Prehistòriques), Universitat de Barcelona, 08001, Barcelona, Spain; Institut d'Arqueologia de la Universitat de Barcelona), Universitat de Barcelona, 08001, Barcelona, Spain) - Sánchez de la Torre, Marta (SERP (Seminari d'Estudis i Recerques Prehistòriques), Universitat de Barcelona, 08001, Barcelona, Spain; Institut d'Arqueologia de la Universitat de Barcelona), Universitat de Barcelona, 08001, Barcelona, Spain)

The use of caves as livestock shelters during the recent prehistory is widely known. The geoarchaeological term *fumier* refers to human-related biogenic input of herbivore (generally ruminant) dung inside of caves and rockshelters. Most of the documented *fumier* deposits show meters of stratified sequences of burned and unburned dung, which are easily recognizable in the field. However, sporadic penning within rockshelters might not leave such a stratigraphic imprint. Here, we present combined microcontextual and biomolecular data of a Neolithic combustion feature at Abric del Xicotó (Alòs de Balaguer, Lleida, Spain). We aim to characterize the functionality of the combustion feature, and

approach animal husbandry strategies by providing information on fuel use and livestock composition. Micromorphological, microremains (faecal spherulites, ash pseudomorphs, and phytoliths), and organic biomarker data (n-alkanes and their $\delta^{13}\text{C}$ stable isotope composition, faecal sterols and bile acids) have been obtained. Preliminary data shed light on the use of the combustion feature, the presence of husbandry activity at the rockshelter, and the nature of the animals and their diet.

4 THE FAECAL MATTER AT HAND – THE UTILISATION OF FAECAL BIOMARKER ANALYSIS IN PALAEOENVIRONMENTAL RECONSTRUCTIONS

Bertheussen, Anastasia (University of Oslo)

This paper will explore the use of faecal biomarker analysis to investigate human-environment dynamics. Prehistoric landscape utilisation of the interior regions of the Scandinavian peninsula is still debated. However, evidence of significant landscape modification in these regions do exist in the form of e.g., the creation of mosaic forest structures. Arguably, considerable effort was made to create spaces or niches in these transitory spaces. Faecal biomarker analysis is increasingly used in archaeological research. However, on the Scandinavian peninsula, few studies have been conducted using this method. Through my research, I aim to utilise faecal biomarker analysis as a supportive tool in multi-proxy paleoenvironmental reconstructions. In this presentation, I aim to discuss the potentials and difficulties of using faecal biomarker analysis for this purpose.

A set of analysis results obtained from Mesna Lake will serve as a starting point for my discussion where faecal biomarkers proved to be highly valuable in supporting the argument of anthropogenic influence. I will then continue by presenting my future research on Aursjøen in the Dovre mountains. Despite being quite early in the research process, Aursjøen has already indicated to be a good research area due to its biodiversity and rich history. More specifically, I am interested in investigating human-faunal relationships as e.g., multiple trapping pits for reindeer have been identified. Faecal biomarker analysis might prove to be a beneficial tool in identifying different faunal markers and overall be used as supportive evidence of the changing human-faunal dynamics.

5 SMELL THE DIFFERENCE: VOLATILE ORGANIC COMPOUNDS (VOCs) AS A RAPID MEANS FOR ASSESSING THE SOURCE OF COPROLITES

Whelton, Helen (University of Bristol) - Zhao, Wanyue (University of Bristol) - Shillito, Lisa-Marie (Newcastle University) - Bull, Ian (University of Bristol)

Coprolites comprise complex mixtures of lipids derived from diet and biochemical processes of the producer. Analysis of lipids preserved within coprolites is well established and a range of faecal biomarkers are routinely used as a means of identification and an indicator of dietary inputs. Faecal lipid biomarker analysis requires extraction and separation of organic compounds before analysis by gas chromatography-mass spectrometry (GC-MS). One of the main drawbacks of this technique is the large sample size required and the laboratory and analytical resource required to separate lipid fractions prior to analysis and identification.

An alternative technique, proposed as a means of fast screening coprolites, is the characterisation of headspace volatile organic compounds (VOCs). The odour of rehydrated coprolites can be used as an informal means of faecal identification. Using this principle, VOCs from coprolites previously analysed and identified by their lipid profiles, were analysed using solid phase micro extraction (SPME) and GC-MS. A number of discriminatory compounds were identified and shown to differentiate between human, herbivore, and carnivore coprolites. Coprolites and their associated sediments could not be differentiated between using this method, suggesting leaching of VOCs into the burial matrix. The analysis of VOCs provides an alternative, more rapid way to characterise coprolite origin.

6 DATING DUNG: RADIOCARBON DATING OVICAPRID FECAL PELLETS

Dunseth, Zachary (Boston University) - Fuks, Daniel (Ben Gurion University of the Negev; University of Cambridge)

Ancient dung is a scarce but important archaeological resource, encapsulating information on past economies and ecologies. At the 2023 EAA meeting in Belfast, we presented a multi-proxy workflow proposal for maximizing non-destructive, semi-destructive and destructive analyses of individual dung pellets. This included using radiocarbon dating on shavings of the outer surface of dung pellets, based on results indicating their efficacy for this purpose. This result is significant for maximal multi-proxy workflows because the outer surface may act as a trap for biomolecular and microbotanical contaminants and is often discarded in coprolite analysis. Building on these results, we conducted a series of follow-up experiments designed to confirm or qualify the efficacy of the pellet exterior for reliable radiocarbon dating. These involve tests for consistency, homogeneity, pretreatment effects, and reliability of radiocarbon dates obtained from dung pellet exteriors. This paper presents the latest findings and highlights additional directions for improving the dating of ancient dung. The apparent utility of fecal pellet exteriors for radiocarbon dating will facil-

itate the application of multiple destructive analyses to single coprolites, particularly for species with medium to small fecal pellets, such as sheep and goat, among others.

7 THE DOG OR ITS MASTER? FURTHER INTERDISCIPLINARY RESEARCH ON COPROLITES FROM STARE GMAJNE ENEOLITHIC PILE-DWELLING SITE IN SLOVENIA

Tolar, Tjaša (ZRC SAZU, Institute of Archaeology) - Caf, Nina (ZRC SAZU, Institute of Archaeology, Ljubljana, Slovenia) - Galik, Alfred (Austrian Academy of Sciences, Austrian Archaeological Institute, Vienna, Austria) - Le Bailly, Matthieu (University of Bourgogne Franche-Comte, Faculty of Sciences and Techniques, Besançon, France)

The initial results on the seven waterlogged preserved Eneolithic dog coprolites from Slovenia discovered in 2007 and 2014 and published in 2019 (Tolar and Galik) and 2021 (Tolar et al.) are now complemented by the analyses of seven newly discovered, waterlogged preserved dog-human coprolites found during the 2021 excavations at the Stare gmajne pile-dwelling site. The preserved pollen, plant and animal macro-remains and parasites indicate that we are probably dealing with two different origins, both that of the dog and that of its master. The differences between the individual coprolites and between the contents of the coprolites and the sediments surrounding them are presented.

TOLAR, Tjaša, GALIK, Alfred (2019) A study of dog coprolite from Late Neolithic pile-dwelling site in Slovenia. *Archaeological discovery*. 2019, vol. 7, no. 1: 20-29.

TOLAR, Tjaša, GALIK, Alfred, LE BAILLY, Matthieu, DUFOUR, Benjamin, CAF, Nina, TOŠKAN, Borut, BUŽAN, Elena, ZVER, Lars, JANŽEKovič, Franc, VELUŠČEK, Anton (2021) Multi-proxy analysis of waterlogged preserved Late Neolithic canine excrements. *Vegetation history and archaeobotany*, vol. 30, no. 3: 107-118.

8 UTILIZING CT SCAN AND LIPID ANALYSIS IN COPROLITE STUDIES: A CASE STUDY OF JOMON SITES IN JAPAN

Shiroishi, Tetsuya (Yamagata University) - Nishida, Yasutami (Niigata Prefectural Museum of History) - Sakiko, Namigata (Archaeological Research Institution of Yokohama, Yokohama Historical Foundation) - Fukui, Junichi (Hokkaido Archaeological Operations Center) - Miyata, Yoshiki (The University Museum, The University of Tokyo)

In this presentation, we introduce a case study of coprolites excavated from shell middens dating back to the Jomon Period (equivalent to the Neolithic Period) in the Japanese archipelago. Previous year, We conducted artifact observation, CT scanning, and lipid analysis on coprolites excavated from two shell middens (Shomyoji and Motomachi shell middens).

A total of 48 specimens were examined, with 25 undergoing CT scanning and 5 subjected to lipid analysis. The non-destructive nature of CT scanning allowed for a larger quantity of specimens to be analyzed, while the destructive nature of lipid analysis limited it to 5 specimens. Indeed, coprolites are highly valuable artifacts in the Japanese archipelago, and it is necessary to analyze them non-destructively whenever possible.

As a result of the analysis, CT scanning revealed numerous fish bones, while lipid analysis also indicated the possibility of marine fish and shellfish. Additionally, gross observation uncovered fish bones bearing dog tooth marks and other “sandy” materials. These “sandy” materials may have contained sand ingested during the meal of a canine, suggesting that the coprolites may be of canine origin rather than human.

In addition, we will report on sites currently under analysis (e.g., Torihama shell mounds) when we present our findings at the EAA 2024 Annual Meeting.

9 UNVEILING INDIVIDUAL DIETARY PROFILES AND CULINARY PRACTICES OF THE PAST: A MULTIDISCIPLINARY ANALYSIS OF PALEOFECES

Maixner, Frank (Eurac Research Institute for Mummy Studies, Bolzano, Italy) - Sarhan, Mohamed (Department CIBIO, University of Trento, Italy; Eurac Research Institute for Mummy Studies, Bolzano, Italy) - Oegg, Klaus (Institute of Botany, University of Innsbruck, Innsbruck, Austria) - Rattei, Thomas (CUBE - Division of Computational Systems Biology, Centre for Microbiology and Environmental Systems Science, University of Vienna, Vienna, Austria) - Reschreiter, Hans (NN) - Moritz, Robert (Institute for Systems Biology, Seattle, USA) - Segata, Nicola (Department CIBIO, University of Trento, Italy) - Zink, Albert (Eurac Research Institute for Mummy Studies, Bolzano, Italy) - Kowarik, Kerstin (Austrian Archaeological Institute, Austrian Academy of Sciences, Vienna, Austria; Prehistoric Department, Museum of Natural History Vienna, Vienna, Austria)

Paleofeces act like a miniature time capsule, providing highly resolved snapshots into individual dietary habits. Various information sources are present in naturally desiccated ancient feces, including plant and animal macro- and micro-fossils, parasite eggs, and biomolecules (DNA, proteins, lipids, and metabolites). Here we will present two multidisciplinary paleofeces studies that unlocked new insights into past cuisines and individual culinary practices through the reconstruction of in-depth dietary fingerprints.

By undertaking a complementary -omics approach, including high throughput sequence analysis of ancient biomolecules and microscopy, we analyzed the stomach content of the 5,300-year-old Iceman mummy, commonly known as Ötzi. Our analysis showed that the Iceman seemed to have had a remarkably high proportion of fat in his diet, supplemented with dried wild meat, cereals, and traces of bracken. Microscopic examination provided in addition first evidence of food preparation methods showing that the Iceman either consumed fresh or dried meat. In our second study we subjected four human paleofeces from the Hallstatt salt mines dated from the Bronze Age to early Modern Times to an in-depth microscopic, metagenomic and proteomic analysis. Our dietary survey identified bran and glumes of different cereals as one of the most prevalent plant fragments. This highly fibrous, carbohydrate-rich diet was supplemented with proteins from broad beans and occasionally with fruits, nuts, or animal food. The miner's diet was complex and included also fermented food. Specifically, fungal analysis of one of the Iron Age samples showed significant levels of *Penicillium roqueforti* and *Saccharomyces cerevisiae* DNA, fungi that ferment blue cheese and beer, respectively.

By integrating findings from multiple disciplines, we could reconstruct holistic portraits of past individual foodways and culinary practices. Importantly, the application of cutting-edge analytical techniques to paleofecal studies continues to push the boundaries of archaeological research, offering new avenues for investigating the past.

1065 ADVANCES IN THE STUDY OF ANCIENT POTTERY: BRINGING SOCIAL ARCHAEOLOGY AND DIGITAL ARCHAEOLOGY TOGETHER

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Oikonomou, Artemios (Science and Technology in Archaeology and Culture Research Center (STARC), The Cyprus Institute; Institute of Nuclear and Particle Physics, NCSR Demokritos) - Kathariou, Kleopatra (Department of History and Archaeology, University of Ioannina, Greece) - Valamoti, Soultana (Aristotle University of Thessaloniki)

Session format: Regular session

Pottery analysis is a means of great importance in archaeological research, as the information it offers helps to better approach and interpret not only the objects themselves but also the archaeological settings they belong to (including domestic, administrative, religious, and funerary contexts) as well as the various activities of the ancient societies they are linked to.

Studying pottery is a demanding task, since it is found in huge amounts at almost all excavation sites around the world and usually in fragments. The application of ICT tools over the recent decades fulfilled the need to record, manage, retrieve and analyze these data. Analytical techniques based on heterogeneous sources (such as drawings, photographs, 3D scans etc.) have been brought together, whereas the creation of pottery databases and digital repositories facilitates the ceramologists' work to manage the plethora of information they deal with as well as to proceed to their pottery-based interpretations.

Furthermore, archaeometric approaches have become over the years a powerful set of analytical tools that allow a deep understanding of the processes of manufacture, the provenance and the use of pottery. Chemical, structural, petrographic analysis and the study of organic residues from ceramic objects have revealed a hidden world allowing us to understand their biography.

Our session aims to move forward through a fruitful dialogue between the different research paths that Digital Archaeology and Archaeometry have developed for the study of ancient ceramics on one hand and major archaeological questions about past human societies on the other. This session will try to put emphasis on the synergistic effects of ICT tools, scientific approaches, and Archaeology to enhance our knowledge about ancient pottery and shed light into daily life, special events and contact networks in Greece and adjacent areas (Italy, Balkans, Eastern-Mediterranean) from Prehistory until the end of Late Antiquity.

ABSTRACTS

1 INTEGRATING CERAMIC PETROGRAPHY AND DIGITAL IMAGE ANALYSIS. INVESTIGATION OF PASTE PREPARATION METHODS AND RESOURCES PROCUREMENT AT OGLIASTRETTO (CS)

Serino, Donatella (Sapienza University of Rome) - Vanzetti, Alessandro (Sapienza University of Rome) - Marino, Sara (Sapienza University of Rome) - Cannavò, Valentina (University of Modena and Reggio Emilia)

The Neolithic (6th millennium BCE) and Copper Age (3rd millennium BCE) settlement of Ogliastritto is located in the southern hilly edge of the Plain of Sybaris (Calabria, Italy). Macroscopic characterization of two pottery assemblages and thin section petrography of n=42 vessels and daub fragments were conducted for the compositional and the technological classification of the ceramic pastes. As a result, the main paste recipe was identified as the IM3

fabric, locally produced and heterogeneous in granulometry, suggesting that different processes were applied to the raw clay materials, like tempering and sieving/fractioning. A minor portion of the pottery assemblage is grouped into macroscopic impasto classes and petrographic fabrics which show a certain compositional variability. While such diversity is representative of the local intrusive-metamorphic lithology, it also allows to infer that various deposits were exploited by local producers, who selected the resources offered by the surrounding environment and landscape. Therefore, to interpret the variability in texture and composition found in the ceramics in terms of paste preparation methods and resources procurement, n=12 samples of clays, silts, sands and soils were further collected within 7 km from the site to characterize locally available raw materials. Petrographic analysis usually involves qualitative descriptions of ceramic fabrics. Here a quantitative approach was adopted by performing digital point-counting on 2D images, in order to achieve an accurate modal and textural analysis and a reliable comparison between raw materials and ceramics. Specifically, the JMicroVision Software was used as a virtual point-counter which generates a grid of random points to be classified and measured. The combination of archaeometry and digital image analysis has represented therefore a valuable tool for the in-depth investigation of deposits exploitation strategies at the local scale, and to better define the local crafting tradition and the social implications involved.

2 BRONZE AGE COOKING CERAMIC FABRICS FROM NORTHERN GREECE AND BULGARIA: TECHNOLOGICAL VARIABILITY AND USES

Dimoula, Anastasia (Eidikos Logariasmos Kondilion Erevnas A.P.TH, Aristotle Univ. of Thessaloniki) - Tsirtsoni, Zoi (UMR 7041-Archéologies et Sciences de l'Antiquité CNRS) - Valamoti, Soultana Maria (Eidikos Logariasmos Kondilion Erevnas A.P.TH, Aristotle Univ. of Thessaloniki)

The clay recipes used in the production of cooking pots and/or cooking ceramic fabrics, commonly share functional characteristics, associated with their intended use over fire. However, their technological features, from the selection and processing of raw materials to firing, differ considerably between settlements and regions, as well as over time. As for evidence of their use, research in this field is rather limited. This presentation integrates macroscopic, analytical, and experimental data obtained within the framework of ERC project PlantCult, in order to explore this technological variability, as well as to establish those properties related to culinary function. Our ultimate goal is to identify specific traces, petrographic and macroscopic, indicative of the use of cooking pots.

Our methodological approach comprises integrated contextual, macroscopic, and petrographic analysis, along with digital data processing and documentation, of a range of cooking pots sampled from eight sites in northern Greece and Bulgaria, dating from the Early to the Late Bronze Age (3rd-2nd mill BC). The study is complemented by the analysis of experimentally manufactured cooking pots, used in a series of cooking experiments. The research results demonstrate that while cooking fabrics in our study area exhibit strikingly consistent functional properties, they are characterised by respective technological variability due to diverse environmental, socioeconomic, or other factors. Additionally, the identification of use traces on ceramic cooking fabrics is facilitated by the comparison between analytical archaeological data and experimental data.

3 INVESTIGATING THE COARSE POTTERY FROM THE SANCTUARY OF KALAPODI. AN ARCHAOMETRIC APPROACH

Christodoulou, Kelly (National and Kapodistrian University of Athens; N.C.S.R Demokritos) - Hein, Anno (N.C.S.R Demokritos)

The present study focuses on the archaeological and archaeometric investigation of the coarse pottery assemblage discovered in the South Temple Sequence of the sanctuary of Kalapodi in ancient Phokis. Coarse pottery in general, is nowadays the main focus of the studies of 'New' Archaeology since they can provide answers to questions related to origin of production and, moreover, pottery exchange, the technological choices made by the ancient potters and the socioeconomic meanings evolving to these human actions. Although studies and publications of this specific ceramic category exist for several sites in Mainland Greece, this is the first study of pottery that derives from a cult place with successive layers of use from Late Mycenaean (LHIII) to Early Iron Age (Late Geometric Period).

The ultimate goal of this research is the examination of the typology and the range distribution of coarse pottery per chronological phase and the comparison of archaeological results with the context, as well as, the results of the analytical techniques (pEDXRF, petrography, SEM). The above combined results showed a remarkable variability and the formation of different coarse categories, based on their elemental composition and petrographic fabric. Analytical techniques presented a clearly selective use of local clay sources for the production of specific Mycenaean (cooking and pithos ware) and geometric coarse vessels (burnished ware). Of quite importance were also the macroscopic and archaeometric results of a very particular and much discussed coarse pottery, the so called Handmade Burnished Ware, which appeared to have a continuous use from Mycenaean to Early Iron Age and different places of origin (local and non-local).

4 MORTARIA FROM KARABOURNAKI, NORTHERN GREECE: TYPOLOGICAL AND PETROGRAPHIC ANALYSES

Manakidou, Eleni (Faculty of Philosophy, School of History and Archaeology; LIRA Laboratory, Department of Archaeology, School of History and Archaeology, University of Thessaloniki, 54124 Thessaloniki, Greece; Center for Interdisciplinary Research and Innovation (CIRI-AUTH), Balkan Center, Buildings A and B, 10th km Thessaloniki-Thermi Rd, P.O. Box 8318, 57001 Thessaloniki, Greece) - Dimoula, Anastasia (LIRA Laboratory, Department of Archaeology, School of History and Archaeology, University of Thessaloniki, 54124 Thessaloniki, Greece; Center for Interdisciplinary Research and Innovation (CIRI-AUTH), Balkan Center, Buildings A and B, 10th km Thessaloniki-Thermi Rd, P.O. Box 8318, 57001 Thessaloniki, Greece) - Valamoti, Soutana-Maria (LIRA Laboratory, Department of Archaeology, School of History and Archaeology, University of Thessaloniki, 54124 Thessaloniki, Greece.; Center for Interdisciplinary Research and Innovation (CIRI-AUTH), Balkan Center, Buildings A and B, 10th km Thessaloniki-Thermi Rd, P.O. Box 8318, 57001 Thessaloniki, Greece)

The coastal site at Karabournaki in Thessaloniki, northern Greece, was one of the most significant harbors of antiquity in the northern Aegean, especially flourishing during the Archaic period (7th-6th c. BC). The intense commercial activities of the site are evident through the ceramic wares present, mainly transport or tableware, deriving from various areas throughout the Aegean and the Eastern Mediterranean. The present interdisciplinary study focuses on a particular domestic ware, the so-called mortaria or ceramic grinding bowls, which are commonly not traded in large-scale, but at Karabournaki they exhibit remarkable quantity and variety.

In this context the aim of the study is twofold. Firstly, to establish the provenance of the mortaria, in order to interpret their role in this trading site. Secondly, to explore their technological attributes (clay composition, vessel building and firing, surface treatment), along with their use-wear traces, both directly linked to their intensive grinding function. To achieve this, the methodology applied included integrated macroscopic typological and petrographic analyses, complemented by digital data processing and documentation. Our study shows that the specific use of mortaria required specialized ceramic fabrics to withstand the mechanical stresses of grinding in food preparation or other workshop activities. Moreover, the results of our study demonstrate that mortaria, originating from various Aegean and Eastern Mediterranean production centers, reached the harbor of Karabournaki in order to be used in situ and also probably to be distributed to neighbouring settlements and the hinterland of Central Macedonia.

5 THE BIOGRAPHY OF THE POTTERY OF WESTERN ACHAEA (DYMAIA CHORA) IN THE CLASSICAL PERIOD. A PRELIMINARY ARCHAEOLOGICAL AND ARCHAEOMETRIC APPROACH

Argyropoulos, Vassilios (Ephorate of Antiquities of Achaia; University of Thessaly, Department of History, Archaeology and Anthropology) - Kougia, Nickoula (Department of Geology, University of Patras) - Iliopoulos, Ioannis (Department of Geology, University of Patras)

In recent years, alongside the discovery of new archaeological sites, the archaeological excavations that have been carried out in the NW Peloponnese and especially in the countryside of western Achaia (Dymaia Chora), have brought to light a significant number of pottery finds. Among them evoke interest grave goods, mainly vases dated to the 5th and 4th century B.C. These are considered to be imported products of Attic, Corinthian or Elean workshops, local productions influenced by western Greek workshops, or typologies encountered across Achaia and Elis. The group of red-figure vases are of particular interest, probably products of a new-appearing pottery workshop in Dymaia Chora, influenced by red-figure pottery of South Italian and especially Apulian workshops.

The research about the vases' biography is not only based on their morphological and stylistic characteristics, but is also complemented by archaeometric techniques. The study of the mineralogical and petrographic characteristics of the ceramic samples allowed us to infer about their provenance and pottery technology. A diverse and comprehensive framework of data collected provided all necessary elements for the documentation and interpretation, not only of the vases, but also of the wider social context to which they belong.

The aim of this synthetic study is to reveal the function of vessels in the context of the burial sphere, also the approach and interpretation of social structures and identities and finally the understanding of socio-economic processes and fermentations, in the 5th and 4th c. BC, in the region of western Achaia.

6 A NEW CENTER FOR CERAMIC PRODUCTION FROM THE ROMAN PROVINCE OF ACHAEA. ARCHAEOLOGICAL DATA AND ARCHAEOMETRIC ASPECTS

Kougia, Nickoula (Department of Geology, University of Patras; ERAAUB, Departament d'Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona) - Iliopoulos, Ioannis (Department of Geology, University of Patras; ERAAUB, Departament d'Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona)

The existence of ceramic kilns in the city of Patras offer concrete evidence of great development throughout the Imperial period, after its foundation as an Augustan colony. The city's role as a major ceramic production center is underlined, mainly due to its key location within regional and long distance trading networks. The rich corpus of ceramic kilns and workshops in Patras' territory, has expanded our understanding of the functional roles they played in urban and rural space. Representative ceramic fragments among the locally encountered typological repertoire of the workshops were studied in conjunction with analytical techniques, in order to determine the local compositional patterns. The archaeometric study and interpretation of pottery through thin-section analysis enabled the classification of different ceramic fabrics. The mineralogical analysis through X-Ray Powder Diffraction (XRPD) allowed us to estimate the equivalent firing temperatures that the pottery has sustained inside the kilns, providing important information about the ceramic technology. Furthermore, the geochemical analysis of the ceramic assemblage offered adequate data for developing a comprehensive geochemical database. The results obtained have helped us to reconstruct local and regional networks of exchange, to unveil practices of the past and understand technological choices.

7 CHEMICAL CHARACTERIZATION OF HELLENISTIC-ROMAN FINE WARES FROM TWO WORKSHOPS IN THE REGION OF ELIS, GREECE: A PRELIMINARY STUDY

Triantafyllidi, Elena (Department of History, Archaeology and Cultural Resources Management, University of the Peloponnese, Old Camp, 24133 Kalamata, Greece) - Tsampa, Kalliopi (X-ray Fluorescence Laboratory, Institute of Nuclear and Particle Physics, NCSR Demokritos 153 10 Aghia Paraskevi Attiki, Greece) - Karydas, Andreas-Germanos (X-ray Fluorescence Laboratory, Institute of Nuclear and Particle Physics, NCSR Demokritos, 153 10 Aghia Paraskevi Attiki, Greece)

The current study aims to outline the pottery tradition of north western Peloponnese by examining a group of Hellenistic-Roman fine wares from two important workshops: Ancient Elis and Ancient Olympia, Greece. Both sites had a flourishing pottery tradition, especially from the Classical period and onwards, something that can be verified from the remnants of pottery kilns. In the current study 40 samples (20 from Ancient Elis and 20 from Ancient Olympia) date in Hellenistic-Roman period, were examined both microscopically and chemically. In the case of Ancient Elis, the material comes from the South Stoa and consists mainly from utilitarian pottery fragments such as black glazed and terra sigillata table wares. In Ancient Olympia pottery comes from a well in Leonidaion and from a Hellenistic bath in a building complex, north of Prytaneion. Leonidaion pottery consists mainly from plain wares, like jugs while Prytaneion pottery represented mainly by utilitarian black glazed and terra sigillata wares. Samples were examined microscopically using LED for a preliminary grouping of the fabrics. XRF analysis using a handheld analyzer was used for the chemical characterization of the clay matrices. The analysis showed that both workshops using highly calcareous clays (CaO>10wt%) for the manufacture of high quality, durable vessels. The microscopic examination revealed that Ancient Elis pottery consists from 5 distinct fabrics while 4 chemical groups were determined based on the CaO content. In general, no microscopical (fabric) and chemical correlation was testified with the exception of the terra sigillata type that forms a distinct group, microscopically and chemically. In Ancient Olympia 7 fabrics were determined while chemically not a distinct chemical group was defined, based on the CaO content. This study provides important new data on western Peloponnesian fine wares by analyzing samples from two thriving workshops of Hellenistic-Roman period.

8 THE VASE, THE CONTENT, THE USE. ORGANIC RESIDUE ANALYSIS OF FIGURED POTTERY IN CONTEXT.

Pola, Angela (Università degli Studi di Pavia) - Bosi, Adele (CNR)

Traditionally, figured pottery has mainly been analysed with the attributive/chronological purposes of identifying painters and workshops and cataloguing its rich figurative repertoire, often underestimating the undeniable fact that beyond the rich mythological representations, a figured vase is also a functional object whose shape and decoration are closely connected to its practical use and function within society. To fill this gap, a new research project on figured pottery from central pre-Roman Italy (*) has developed an interdisciplinary approach to study the uses and functions of figured vases. This project allows the investigation of the relationship between shapes, uses, and contents, their consistency and possible variation in connection with different contexts (necropolis, sacred areas, inhabited areas), through a diachronic perspective including the study of imports and local production. With the application of organic residue analysis (ORA), the use of the vases is analysed by identifying the commodities they once contained. The

combination of archaeological methodology and archive research allow us to re-contextualise the vases, investigating their function in their archaeological discovery context and the broader socio-economic and cultural context of the society in which they were used. The paper briefly presents the project, focusing specifically on the problems derived from performing ORA to highly valuable decorated ceramics, the development of a new analytical methodology for the determination of molecular markers from ancient complex matrices, and a new extraction/clean-up protocol and HPLC-MS/MS analysis after derivatisation, providing an archaeological interpretation of some of the first results achieved.

9 CAPACITY OF SYMPOTIC VESSELS IN THE LATE CLASSICAL PERIOD: REFLECTIONS ON THE CHANGES OF DRINKING HABITS

Kathariou, Kleopatra (University of Ioannina, Greece)

The capacity of a vessel is related to its function since form follows function. It is true that there are not many studies of vessel capacities so far; the existing isolated ones focus on black-figured attic vases exported to Italy or red-figure and black-glazed ones found in the excavations of the Athenian Agora. In this presentation we will focus on drinking vessels made in specific workshops of the late 5th and the early 4th century BC, when production of well potted and decorated vases was gradually replaced by mass vase manufacture.

The dominance of cups was later followed by smaller, more practical shapes, e.g. stemless and cup-skyphoi. What do the changes over time in vase shapes and their capacities tell us? Does the significantly smaller volume suggest changes in drinking habits, the consumption of less wine or different drinking activities?

Serving and mixing vessels will be studied in parallel to drinking vases either when produced in the same workshop or when found in an assemblage, in order to examine whether there is a functional relationship between them. In the cases of workshops, where red-figure drinking vases are known to have been produced together with black-glazed ones we will examine the differences in their capacity.

With this study, by bringing capacity into discussion we will try to connect pottery to everyday life and to trace changes in consumers' behavior towards its use.

10 SIZE DOES MATTER - WHAT THE CAPACITY OF DRINKING VESSELS CAN TELL US ABOUT THE INSTRUMENTALISATION OF CONSUMPTION HABITS

Dauth, Thomas (University of Innsbruck)

By the 4th century BC at the latest, black-glazed pottery had advanced from a luxury item to a mass product. In ceramic production centres around the Mediterranean, new vessel forms were developed to meet local needs. An initial review from the most recent excavations on Monte Iato in inland of western Sicily revealed striking similarities but also discrepancies within the ceramic find material. In particular, black-glazed drinking vessels showed a high degree of variability, both in terms of shape and capacity. This diversity is not reflected in current research on Hellenistic pottery. Rather, a study of the relevant publications gives the impression that new types of drinking vessels replaced older types and became progressively smaller from the 4th to the 2nd century BC, which can be attributed to changes in consumption habits. As findings from Monte Iato show, the change in consumption habits was not abrupt. Rather old consumption patterns may have been instrumentalized for social and political purposes, at least in selected situations.

The simplest and most time-efficient method of calculating the capacity of vessels is to use CAD programs to convert profile drawings into 3D objects and read the volume directly from them. In this way it is possible to calculate the average capacity, as well as the ratio between diameter, height and volume, of the most common types of drinking vessels from a large number of published vessels. This allows an approximate capacity to be calculated even for vessels that are only preserved in fragments but whose type can be determined. Fragments from stratified contexts can then be compared with these average values, allowing conclusions to be drawn about different, sometimes coexisting, consumption habits. This, at least in the case of Monte Iato, allows interesting conclusions to be drawn about everyday life, traditions and consciously represented identities.

11 APPROACHES TO CERAMIC ILLUSTRATION IN A DIGITAL AGE. EVALUATING AND COMPARING DIFFERENT METHODOLOGIES

Bruderer, Oliver (University of Zurich, Department of Archaeology)

Archaeological illustrations are an important means for understanding and communicating pottery remains found on archaeological excavations – quite often in huge quantities. With the ongoing digitisation various digital technologies support the illustration of pottery and have the potential to replace the traditional measuring and drawing by hand. There are, for example, automated drawing tools like the “Laser Aided Profiler” (laseraidedprofiler.com), or one can apply 3D documentation, as for example ‘Structure from Motion’. Whereas in the traditional hand drawing every line gets measured and drawn intentionally (and controlled) by the illustrator, the digital methods draw shapes based on

optical-mathematical measurement. Thus, they are influenced – and sometimes limited – by various physical parameters.

Upon closer inspection many of the assumed advantages as for example “making the drawing more precise”, “making the process faster”, “making the method easier to use” need to be reconsidered. But which method serves which purpose? What are the benefits of digital methods, and where are their limits?

As many in the fields, the Monte Iato excavation project of the University of Zurich has been confronted with these questions. A systematic evaluation of the above mentioned methods (traditional drawing / «Laser Aided Profiler» / «Structure from Motion») was done with artefacts in the Archaeological Collection in Zurich as well as with excavation material in Sicily.

12 IMAGES ON GREEK POTTERY “SEEN” BY A COMPUTER

Reinhardt, Corinna (Universität Zürich, Institut für Archäologie, Fachbereich Klassische Archäologie)

Images on ancient Greek pottery as sources for the study of ancient societies and their thinking are a well known topic in the discipline of Classical Archaeology and look back on a detailed and elaborate methodology. New developments of Artificial Intelligence, for example in the field of comparing and identifying images (and texts) present the discipline with challenges and new opportunities. Distant viewing of a larger dataset or an image-based search of similar poses, gestures or objects within the images provide a fresh look at a familiar material. However, these are only the beginnings of a digital archaeology in the field of image studies.

The presentation, thus, seeks to explore some of the potential of using methods of (mainly) Computer Vision in the study of Greek vase paintings and at the same time identifies problems for further developments. It is based on the results of a project which began at Friedrich-Alexander-Universität Erlangen Nürnberg/ Germany with funding from the Emerging Fields Initiative of the University from 2019-2022. It called Iconographics: Computational Understanding of Iconography and Narration in Visual Cultural Heritage. There, colleagues from the disciplines of Art History, Christian Archaeology, Classical Archaeology and the team of the Pattern Recognition Lab worked together on the challenge of developing image recognition and else for the humanities.

13 FROM REALIA TO VIRTUAL REALITY. A PROJECT OF MEDITERRANEAN ARCHAEOLOGICAL HERITAGE VALORISATION OVERSEAS THROUGH DIGITAL ARCHAEOLOGY AND AI

Mandic, Josipa (Aix-Marseille Université) - Saltini Semerari, Giulia (University of Michigan) - Vita, Cesare (Université Rennes 2)

This paper presents a project for the valorisation of matt-painted pottery found in Southern Italy through the creation of a virtual 3D models database hosted by the Museum of Anthropological Archaeology (University of Michigan) for scientific and didactic purposes. Matt-painted ware is one of the most tangible expressions of indigenous cultural identity between the 9th and 6th centuries BCE and a valuable source for understanding local funerary, domestic and ritual contexts and interactions dynamics during the Greek colonization. This pottery has been subject, in the last 30 years, to chrono-typological, contextual and archaeometric analyses resulting in a well-defined chronological, stylistic and technological framework. This project aims to take a step forward in the study of this material culture by harnessing Digital Archaeology and AI technologies in order to (1) create a public database for the valorization, research and teaching of this ware and (2) provide a useful case study for similar future initiatives. The project will create virtual 3D restitutions of a comprehensive dataset of regional and chronological specimens, which will be searchable for identification and 3D printing. The scientific aim of this project is the creation of a virtual depository of data for the implementation of AI software for the recognition of shapes and decorations of matt-painted pottery. The didactic aim is to facilitate, also overseas, the fruition and knowledge of those less treasured Mediterranean cultures through their virtual exhibition and use of new technologies.

14 MAKING SENSE OF HELLENISTIC POTTERY: PAST, PRESENT, AND FUTURE

Laftsidis, Alexandros (CReA-Patrimoine (ULB))

Research interest on Hellenistic pottery presented a notable delay in relation to the study of ancient Greek ceramics from other historical periods. It was not until the late 1980s that the study of Hellenistic pottery gained considerable traction. Fast forward a few decades, and our understanding on workshops, local ceramic traditions, trade networks and particularly the chronological distribution of different vessel-types has dramatically improved. The advancements, though, in the employment of scientific analysis and the hitherto attempts towards synthetic works moving away from merely positioning the examined pottery in time and place leave much to be desired. This situation begs the question of what the preferable approach to the study of this ceramic evidence should look like moving forward.

The paper attempts to offer an answer to the above question, aspiring to simultaneously provide a tentative theoretical framework for handling ceramic assemblages of the period. First, the use of archaeometric analysis should become

more widespread, joining forces with traditional archaeological approaches to answer questions of production, use, and provenance of pottery. Also, the wider application of software solutions, such as pottery databases, can facilitate the 'taming' of the overwhelming amount of pottery and allow for patterns of similarities/differences to emerge on a local and/or supra-local level. All the above approaches, however, should be informed by theory, which could help navigate through different interpretations and avoid unnecessary steps in analyzing pottery. Further, the underused so far scientific area of psychology can offer promising theoretical support. Finally, one should never lose sight of the ultimate goal, namely the enhancement of our understanding of Hellenistic societies. Treating our ceramic evidence as the remains of social practices, after it has been placed in its correct socio-economic and political contexts, could bring us one step closer to the realization of this difficult task.

15 THE CRACKING THE CODE PROJECT; ANCIENT TALES FROM THE GRAVE. A QUANTITATIVE APPROACH TO AN UNKNOWN PROTOGEOMETRIC COMMUNITY FROM AETOLIA

Simoni, Eleni (University of Patras) - Christakopoulou, Olga (Hellenic Ministry of Culture and Sports)

The Protogeometric cemetery at Stamna in Aetolia, Greece consists of over 500 burials, most of which date back to a very short period between 900-800 BC. The way most of the cemetery has been unearthed (rescue excavation prior to the construction of a highway) points to a promising site, the full extent of which could not be revealed and will take a very long time until this happens. Therefore, the application of every available method to understand the short but flourishing life of the settlement in a period relatively unknown in Mediterranean archeology is welcome and highly sought after.

In this article we will focus on the 267 burial pithoi of the cemetery. From the material published to date, we can classify them into 11 categories based on their manufacture. Additional data concerns the typology, quantity and decoration of the abundant grave-goods that accompanied them. Even though the site is not visible anymore, a very important piece of information, the spatial identity of the pithoi has been recorded. We know that they were located inside 27 burial clusters and make up more than half of the total graves of the site.

After having georeferenced the clusters, we apply a series of available GIS tools (spatial analysis, spatial statistics, KDA) and attempt to answer questions concerning the social and economic character of the settlement, about which nothing else is known. Are there significant differences among the burials in the different clusters? Does the distribution of pithoi and their offerings reflect a stratified society? Are contacts with other areas occurring? In this way, we propose a multidimensional excavation data processing tool and we highlight the importance of very thorough spatial recording in rescue excavations.

16 A MASS OF FUSED LAMPS FROM LATE ANTIQUE ATHENS - DIGITAL RECONSTRUCTION AND INTERDISCIPLINARY ANALYSIS

Petrakis, Manolis (Directorate of the National Archive of Monuments; National Archaeological Museum, Athens)

This paper explores an intriguing mass of fused wasters at the National Archaeological Museum in Athens. Comprising approximately one hundred intact or partially preserved terracotta lamps dating to the 4th century CE, it represents the largest known failed batch of lamps from a pottery kiln in Greece. Acquired by the museum in 1865 from the antiquities dealer Dimitrios Giagias, according to whom it was discovered in Metaxourgeion (next to the Athenian Kerameikos), this lamp mass is exhibited in the Museum's Vase Collection. However, technical difficulties, such as the fragile nature of the object, have hindered its thorough examination, making even its observation from all angles extremely difficult.

This paper addresses these challenges by applying ICT tools, aiming to provide a comprehensive analysis of the lamps-mass. Using photogrammetry, a 3D model has been created to document and study the challenging object, replacing traditional macroscopic analysis. Through the examination of this model, the paper endeavors to contextualize the find, determine its date, attribute the lamps to specific pottery workshops, and enhance our understanding of the lamp manufacturing process and the utilization of pottery kilns in Late Antique Athens. Furthermore, comparisons with samples from the workshops of neighboring Kerameikos have been conducted to confirm the provenance of the failed batches.

In addition to digital analysis, the paper employs archaeometric techniques, including X-ray examinations, to gain sight into the interior of the lamp mass. By integrating these multidisciplinary approaches, this study seeks to contribute to our understanding of ancient ceramic production and trade networks in the region and to demonstrate the use of 3D models in archaeological studies.

1068 AGRARIAN CHANGE IN THE MEDIEVAL MEDITERRANEAN: TOWARDS HOLISTIC ARCHAEOLOGIES OF ENVIRONMENTAL CHANGE

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Pluskowski, Aleks (University of Reading) - Kirchner, Helena (Autonomous University of Barcelona) - García-Contreras, Guillermo (University of Granada) - Alexander, Michelle (University of York)

Session format: Round table (without formal abstracts)

As the Mediterranean rapidly enters a new era of changing climate, holistic archaeologies can offer vital perspectives on how societies responded to environmental challenges through innovation and adaptation during the formative 'long Middle Ages'. This aim of this roundtable is to discuss how we can best approach the varied and fragmented data to better understand the relationship between societal and environmental change in the medieval Mediterranean. The recently begun ERC synergy project "Re-thinking the "Green Revolution" in the Medieval Western Mediterranean (6th - 16th centuries)" (MEDGREENREV) provides a framework for exploring the opportunities and challenges of integrating different types of archaeological, historical and environmental data, as well as scales of analysis, relevant theoretical frameworks and comparative approaches.

During this roundtable, we would like to explore:

- 1) Key research questions for archaeologies of environmental change
- 2) The challenges of integrating different types of data
- 3) The challenges of dating and robust chronologies
- 4) Long-term versus short-term perspectives on environmental change
- 5) The role of climate
- 6) Accommodating different theoretical frameworks
- 7) Comparative approaches across the Mediterranean world
- 8) Lessons for the future

We invite everyone interested in the complex relationship between societal and environmental transformation in the medieval Mediterranean to contribute to this discussion.

1071 MACHINE LEARNING METHODS IN ARCHAEOLOGICAL RESEARCH: NEW APPROACHES, BARRIERS AND STANDARDIZATION

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Berganzo-Besga, Iban (Ramsey Laboratory for Environmental Archaeology (RLEA), University of Toronto Mississauga) - Jakubczak, Michał (Institute of Archaeology and Ethnology, Polish Academy of Science) - Bulawka, Nazarij (Catalan Institute of Classical Archaeology) - Troiano, Maurizio (Department of Information Engineering, Electronics and Telecommunications (DIET) - University of Rome "La Sapienza"; Research Unit of Molecular Genetics of Complex Phenotypes, Bambino Gesù Children's Hospital, IRCCS, Rome) - Nobile, Eugenio (The Sonia and Marco Nadler Institute of Archaeology, Tel Aviv University)

Session format: Regular session

During the last years we have entered a new phase in the application of artificial intelligence (AI) in archaeology. The main advances within machine learning (ML) and deep learning (DL) have been successfully implemented in multiple archaeological case studies. However, it is easy to see that the use of these new methods comes with its own set of problems, and lack of a common procedure and standardization.

The variety of applications includes sites detection and material culture analysis, showing that these methods are able to define a wide spectrum of socio-economic aspects of the societies, such as the individual preferences of craftsmen, the technological mindset of the communities, or their exchange of ideas beyond any geographical borders.

At this session, in order to integrate the archaeological ML research into general archaeological practice, we would like to welcome every researcher who struggles with the above problems and also:

- All case studies on the application of AI, especially with the use of new algorithms and approaches to different sources of archaeological information with a clear focus on improvements.
- Analyses of how ML and DL have been implemented in archaeological research with a clear focus on the issues that have arisen and those studies that have proposed solutions to these issues. Plans for the use of these methods and the barriers researchers are encountering.

- Best practices and procedures, which can include comparative analysis, of how to approach the most common issues in archaeological research, such as the small amount of training data available.
- Ethical issues in ML-based archaeological research with a particular focus on the growth that AI has had globally during the last year.

ABSTRACTS

1 A DEEP LEARNING BASED TAPHONOMIC STUDY OF DS (BED I, OLDUVAI GORGE) AND ITS IMPACT ON RECONSTRUCTING EARLY HOMININ-CARNIVORE INTERACTIONS

Jiménez-García, Blanca (Universidad de Alcalá; Instituto de Evolución en África) - Cifuentes-Alcobendas, Gabriel (Universidad de Alcalá; Instituto de Evolución en África) - Baquedano, Enrique (Museo Arqueológico y Paleontológico de la Comunidad de Madrid; Instituto de Evolución en África) - Domínguez-Rodrigo, Manuel (Universidad de Alcalá; Instituto de Evolución en África; Rice University)

The importance of accurately identifying bone surface modifications (BSMs) has sparked considerable discussions regarding suitable methodological and interpretive frameworks for discerning taphonomic agents and their patterns of bone modification within dynamic taphonomic processes, particularly those involving interactions between different agencies.

Although efforts have been made to devise various comprehensive and objective experimental criteria to aid in detecting specific taphonomic agency, these criteria have largely remained unchanged for several decades, making it difficult to reach a consensus on the application of appropriate objective standards. Here, machine learning and convolutional neural networks demonstrate significant potential in accurately identifying and characterizing bone surface modifications.

The results depicted here contribute significantly to the ongoing discourse on early hominin behavior, emphasizing the importance of integrating traditional and AI-driven methodologies in taphonomic research.

In this study, we provide a thorough examination of the faunal assemblage retrieved from level 22A of DS (David's Site) within Bed I of Olduvai Gorge combining traditional methods based on quantification and physical attributes of the assemblage and more novel approaches based on deep learning and computer vision tools. These findings make a substantial contribution to the still ongoing discussion on early hominin behavior, emphasizing the importance of integrating traditional and AI-driven methods in taphonomic research. This holistic approach enhances our ability to identify specific carnivore agencies, better understand carnivore-hominin interactions, and reconstruct their roles within any given taphocoenosis.

2 A NEURAL NETWORK ANALYSIS FOR METRICS PREDICTION OF PRE-POTTERY NEOLITHIC-B LAMINAR ARTEFACTS FROM SOUTHERN LEVANT

Nobile, Eugenio (The Sonia and Marco Nadler Institute of Archaeology, Tel Aviv University, Israel.) - Troiano, Maurizio (Department of Information Engineering, Electronics and Telecommunications (DIET) - University of Rome "La Sapienza", Italy.; Bambin Gesù Paediatric Hospital.) - Mangini, Fabio (Department of Information Engineering, Electronics and Telecommunications (DIET) - University of Rome "La Sapienza", Italy.) - Mastrogiuseppe, Marco (Department of Information Engineering, Electronics and Telecommunications (DIET) - University of Rome "La Sapienza", Italy.) - Vardi, Jacob (Israeli Antiquities Authority, Israel.) - Gopher, Avi (The Sonia and Marco Nadler Institute of Archaeology, Tel Aviv University, Israel.) - Frezza, Fabrizio (Department of Information Engineering, Electronics and Telecommunications (DIET) - University of Rome "La Sapienza", Italy.) - Conati Barbaro, Cecilia (Department of Sciences of Antiquities, University of Rome "La Sapienza", Italy.)

The Pre-Pottery Neolithic B phase (10,600-9,000 years Cal B.P) is highly characterised by laminar production all over the Levant (Syria, Lebanon, Jordan and Israel) and South-eastern Anatolia (Turkey). This specific chrono-cultural phase consists of a specific reduction process that is aimed to produce mainly blades and secondarily bladelets. The laminar production represents indeed the main technological blank for tools shaping (e.g. arrowheads, sickle elements, borer/awls etc...) and tool resizing/recycling (e.g. multiple or combined tools). However, the conservation of such artefacts is often highly affected by several anthropic and natural causes, such as rituals, recycling activities and/or post-depositional processes. We therefore developed a methodology that aims to solve the laminar artefacts' metrics lack using a machine learning approach, specifically a neural network analysis based on a Bayesian regularization training algorithm.

The neural network analysis was carried out on Middle PPNB sites from the Southern Levant such as Motza, Yiftahel, and Nahal Reuel (Israel).

3 CLASSIFICATION OF GLASS BEADS BY IMAGE CLUSTERING FROM EARLY MEDIEVAL AUSTRIAN SITES

Tobias, Bendeguz (Österreichische Akademie der Wissenschaften - Institut für Mittelalterforschung) - Seidl, Benedict (University of Vienna, Institut für Urgeschichte und Historische Archäologie) - Miklautz, Lukas (University of Vienna, Faculty of Computer Science Research Group, Data Mining and Machine Learning) - Plant, Claudia (University of Vienna, Faculty of Computer Science Research Group, Data Mining and Machine Learning)

Glass beads were among the most common grave goods in the Early Middle Ages, with an estimated number in the millions. The color, size, shape and decoration of the beads are diverse leading to many different archaeological classification systems that depend on the subjective decisions of individual

experts. The lack of an agreed upon expert categorization leads to a pressing problem in archaeology, as the categorization of archaeological artifacts, like glass beads, is important to learn about cultural trends, manufacturing processes or economic relationships (e.g., trade routes) of historical times. An automated, objective and reproducible classification system is therefore highly desirable. We present a high-quality data set of images of Early Medieval beads and propose a clustering pipeline to learn a classification system in a data-driven way.

The pipeline consists of a novel extension of deep embedded non-redundant clustering to identify multiple, meaningful clusterings of glass bead images. During the cluster analysis we address several challenges associated with the data and as a result identify high-quality clusterings that overlap with archaeological domain expertise. To the best of our knowledge this is the first application of non-redundant image clustering for archaeological data.

4 AI CLASSIFICATION OF CERAMIC SHERDS: NEW FRONTIERS FOR THE ARCHAIDE PROJECT

Saraceni, Quirino (Department of Computer Science, University of Pisa) - Gattiglia, Gabriele (Department of Civilisations and Forms of Knowledge, University of Pisa) - Dubbini, Nevio (Miningful SRLS)

In recent years, there has been a growing emphasis on incorporating Artificial Intelligence (AI) methodologies in Archaeology, aimed at automating data processing, leaving archaeologists more time and resources for non-automatable tasks. In this regard, the ArchAIDE project (H2020 RIA, GA 693548) provided an automatic classification tool for ceramic fragments' decoration through a photo. Such a system has been the base for further research projects, e.g. developing a robotic platform to manipulate the fragments, exploiting the potential of ArchAIDE. To reach the goal, the improvement of the initial deep learning (DL) system, developed in TensorFlow 1.x and based on ResNet101, has been necessary.

ArchAIDE framework has first been ported to PyTorch, which provides dynamic control over graphs and facilitates code updates. Then the original Convolutional Neural Network has been fine-tuned - e.g. trials on dropout and intermediate features, addition/deletion of final layers - and other DL models have been explored, such as ResNet50 and Google Inception_v3. Top-5 accuracy has been improved from the original ~75% to ~90% and the top-1 accuracy from ~40% to over 60%, with ResNet50.

Moreover, we introduced the implementation of Continual Learning (CL), which lets the network incrementally add new instances and classes without re-training from scratch, porting ArchAIDE onto a CL framework (Avalanche). Such an approach will make ArchAIDE improvable with new ceramic types and classes more easily. Both the introduction of new instances into the existing ones (domain-incremental scenario) and new classes into the network (class-incremental scenario) got a fair top-5 accuracy, i.e. ~60%, and a top-1 accuracy comparable to that of the first version by ArchAIDE, i.e. ~40%.

The update and the CL approach are able not only to enhance recognition but also to future-proof ArchAIDE and make it more sustainable, enabling ongoing alignment with evolving data and research priorities.

5 EMPLOYING MACHINE LEARNING TRANSFER KNOWLEDGE TECHNIQUES FOR IMPROVED FUNGAL RECOGNITION IN ARCHAEOLOGICAL MICROSCOPY IMAGERY

Mircea, Cristina (Department of Molecular Biology and Biotechnology, Faculty of Biology and Geology, Babes-Bolyai University, Cluj-Napoca, Romania) - Mircea, Ioan Gabriel (Department of Computer Science, Faculty of Mathematics and Informatics, Babes-Bolyai University, Cluj-Napoca, Romania)

The present research aims at tailoring current Computer Vision Machine Learning models to the particular task of classification and recognition of fungal communities in the context of ancient archaeological fabrics studied using Scanning Electron Microscopy (SEM).

As state-of-the-art approaches towards the classification and recognition of various entities in imagery have had exponential success growth rates for the past decade, it is only fair to suppose a custom-tailored deep learning model will perform properly given proper training on such tasks.

The research is conducted in a highly transdisciplinary fashion, the bioarchaeologists being the element to the success of the endeavor as they will provide both the qualitative input data for training as well as the feedback for assessing the performance of the proposed Computer Vision Deep Learning model for continuous improvement and validation purposes.

The training of the models will be conducted on a curated dataset obtained from the literature with an emphasis on the data harvesting and preprocessing stages. The attention will focus on highly qualitative SEM imagery depicting a comprehensive range of fungi associated with archaeological textiles. The validation will be performed on modern textiles reinoculated with species of fungi isolated from the original archaeological textiles.

6 TOWARDS A SHARED PRACTICE FOR DEEP LEARNING APPLICATIONS TO LIDAR-BASED ARCHAEOLOGICAL PROSPECTION

Poggi, Giulio (Istituto Italiano di Tecnologia) - Sech, Gregory (Istituto Italiano di Tecnologia) - Jaturapitpornchai, Raveerat (Istituto Italiano di Tecnologia) - Fiorucci, Marco (Istituto Italiano di Tecnologia) - Traviglia, Arianna (Istituto Italiano di Tecnologia)

Deep Learning (DL) applications in LiDAR-based archaeological prospection assist the manual screening of extensive territorial data with beneficial implications for studying and safeguarding archaeological landscapes. However, the implementation of DL is still far from identifying shared best practices widely applicable to a range of archaeological features differing in size and shape and located in diverse geographical and geomorphological contexts. In addition, the scarcity and restricted scale of archaeological datasets often impose constraints on experimental settings, impeding the pursuit of general trends in the definition of tools and methods.

This presentation presents the results of a comprehensive testing framework aimed at facilitating the selection of appropriate preprocessing methods for DEM-derived products (visualisations) and DL model configurations for enhancing semantic segmentation performance in archaeological applications. This study assesses the influence of diverse visualisations and model configurations in identifying five different archaeological classes on two geographically distinct datasets in the Netherlands and Mexico.

Results show that the selection of the appropriate visualisation influences the overall performance of DL models up to 8%, although it is not possible to identify one visualisation that outperforms the others in all archaeological classes. Performance varies up to 25% across different model configurations and visualisations, underlying the importance of selecting the right match between visualisations and configurations. Lastly, this presentation evaluates how the combined use of the two different datasets can improve semantic segmentation performance by using transfer learning techniques from archaeological datasets instead of general-purpose images (e.g. ImageNet). Preliminary results suggest that this method is a valuable solution to overcome some issues related to the limited size and scarce availability of archaeological datasets.

7 CHALLENGES AND SOLUTIONS IN AUTOMATED LARGE-SCALE ARCHAEOLOGICAL MAPPING WITH DEEP LEARNING: INSIGHTS FROM DTM ANALYSES IN POLAND

Jakubczak, Michal (Institute of Archaeology and Ethnology, Polish Academy of Science) - Tyszkiewicz, Michal (École Polytechnique Fédérale de Lausanne (EPFL)) - Leloch, Michal (Faculty of Archaeology, University of Warsaw)

Recent years have seen numerous projects leveraging machine learning across various fields of archaeology and beyond. Researchers are increasingly recognizing the vast potential of this technology. Yet, we are at the early stages of developing efficient, practical, and accessible machine learning tools for archaeology, necessitating the formulation of a comprehensive methodology.

Thanks to the ISOK project, which focuses on flood protection, we now have free access to a Digital Terrain Model (DTM) of Poland. This model, generated from LiDAR data with a measurement density of 4 to 12 points per square meter, enables the effective remote sensing of many archaeological sites. However, with forested areas alone spanning almost 100,000 km², conducting manual analyses across the entire region is an enormous challenge, likely unfeasible for a small team. Neural networks have emerged as a solution to this issue.

In our paper, we aim to present the outcomes of use of neural networks for the remote sensing of archaeological sites preserved in the land's relief. Our project focused on mounds, charcoal piles, and trenches. We will discuss not only our outcomes but also the significant challenges encountered in data preparation, processing, and result interpretation.

8 COMPUTER VISION BEST PRACTICES IN COMPUTATIONAL ARCHAEOLOGY

Berganzo-Besga, Iban (Ramsey Laboratory for Environmental Archaeology (RLEA), University of Toronto Mississauga (UTM)) - Orengo, Hèctor (Landscape Archaeology Research Group (GIAP), Catalan Institute of Classical Archaeology (ICAC); Catalan Institution for Research and Advanced Studies (ICREA)) - Lumbreras, Felipe (Computer Vision Center (CVC), Autonomous University of Barcelona (UAB))

Landscape Archaeology has progressed enormously in recent years thanks to the introduction of new computer vision (CV) technologies (Argyrou and Agapiou, 2022). In particular, Machine and Deep Learning (ML and DL)-based approaches have demonstrated a wide range of archaeological applications beyond site detection, such as geochemical analysis (Oonk and Spijker, 2015) phytolith detection and classification (Berganzo-Besga et al., 2022a), and the identification of ceramic fragments (Wright and Gattiglia, 2018) between others.

This presentation is intended to provide a guide for the application of ML in archaeological research through a list of best practices. Both training and validation approaches will be presented. The most common problems encountered by archaeologists will be considered, such as the low-density of archaeological features to be detected and the small amount of training data available (Berganzo-Besga et al., 2023). Likewise, a series of methods will be shown to deal with the high number of false positives usually present in the algorithms' results.

The main objective of this talk is to present a comprehensive guide on the design, application, and validation of CV methods, the most common technology within the field of computational archaeology, for the automated identification of archaeological features.

9 INVESTIGATING DOCUMENT AI FOR ARCHAEOLOGICAL REPORTS: A COMPARATIVE ANALYSIS

Santos, Ivo (CIDEHUS - Universidade de Évora; HPC-Chair - Universidade de Évora)

The recent surge in Machine Learning (ML) and Artificial Intelligence (AI) has catalyzed the growth of various fields, including archaeology, possibly pushing into a new era. Evidence of this growth is demonstrated by the constant evolution, expansion and publication of models, datasets, algorithms, and related resources. Some of these efforts are only accessible through a paywall, others push the user to use APIs, but many are freely accessible through platforms such as HuggingFace and GitHub.

This work focuses on an endeavor to extract information from Portuguese archaeological reports, primarily in PDF format, with tools generically identified as Document AI and integrated into the author's PhD project. The corpus is composed of almost, 11000 documents, some digitally born, mostly following different formal structures.

Despite the plethora of tools, algorithms, and datasets saturating the AI landscape, the study aimed to evaluate the efficacy of some of these approaches, with a particular emphasis on accessibility.

We must acknowledge that the revolutionizing nature of the moment implies that this work may soon be describing already overshadowed technologies, not including new cutting-edge approaches, but we believe that the documentation and dissemination of our conclusions could benefit other researchers in their current and future endeavors.

10 APPLICATION OF A DEEP CONVOLUTIONAL NEURAL NETWORK TO SATELLITE IMAGERY FOR THE DETECTION OF PREHISTORIC STRUCTURES IN THE SAHARA DESERT

Brucato, Alessia (University of Bari Aldo Moro (UNIBA); National Research Council of Italy, Institute of Heritage Science (CNR ISPC)) - Taggio, Nicolò (Planetek Italia, GEOAI) - Masini, Nicola (National Research Council of Italy, Institute of Heritage Science (CNR ISPC)) - Scardozzi, Giuseppe (National Research Council of Italy, Institute of Heritage Science (CNR ISPC)) - Lucarini, Giulio (National Research Council of Italy, Institute of Heritage Science (CNR ISPC))

This research introduces a DeepLearning-based approach on satellite imagery to detect and classify archaeological prehistoric structures related to the Holocene period and distinctive of two macro-regions of the Sahara Desert.

Given the challenges of ground-based surveys in these regions, this study aims to enrich our understanding of Saharan prehistoric groups' occupation models, mobility patterns, and their role in exchanging goods and knowledge. The first case study explores settlements and temporary encampments of hunter-gatherers and herders in the oases of the Egyptian Western Desert during the Early and Middle Holocene. The analysis will concentrate on distinctive features such as the slab structures, a type of stone hut foundation, and the Steinplatz-type hearth-mounds, both characteristic of this region. The second case study focuses on landmark monuments associated with Middle and Late Holocene pastoral groups. These monuments, including 'Keyhole,' 'Antenna,' 'Croissant,' and 'V' tumuli, are located in the central and western Sahara, and date between the 4th and the 2nd millennium BC.

This study utilizes a diverse set of satellite imagery, including very-high-resolution optical images (Bing Maps, Google Earth), satellite panchromatic photos from the Cold War era (Hexagon KH-9, Corona KH-4B), and multispectral and radar data (ESA's Copernicus Sentinel).

The satellite images are processed using both cloud platforms and local software (Google Earth Engine, SASPlanet, QGIS) to highlight potential archaeological sites through image-enhancing techniques such as Spectral Indices and PCA. The processed dataset, combined with information from the archaeological record, was prepared to train a Deep Convolutional Neural Network (Ultralytics YOLOv8) for the identification of similar archaeological features.

Preliminary results indicate that the algorithm effectively detected potential new archaeological features, subsequently validated through visual inspections and on-site verifications. This methodology showcases the capability of integrating satellite imagery and Artificial Intelligence to unveil previously undiscovered archaeological sites in desert environments.

11 DEVELOPING A MACHINE LEARNING TOOL FOR THE IDENTIFICATION OF ARCHAEOLOGICAL FEATURES IN LANDSCAPE DATA

Curran, Susan (The Discovery Programme) - Corns, Anthony (The Discovery Programme) - O'Keeffe, John (The Discovery Programme) - Kokalj, Žiga (ZRC SAZU) - Čož, Nejc (ZRC SAZU) - Kocev, Dragi (Bias Variance Labs) - Kostovska, Ana (Bias Variance Labs) - Dimitrovski, Ivica (Bias Variance Labs) - Davis, Stephen (University College Dublin)

The demand for utilising machine learning (ML) in archaeology is steadily rising due to the swift advancement of image analysis techniques and the increasing accessibility of high-quality airborne laser scanning data (ALS). The Automatic Detection of Archaeological Features (ADAF) tool has been developed to offer user-friendly software utilising ML models, particularly convolutional neural networks, for the automatic detection of archaeological features from ALS data. The ADAF tool has been funded by Transport Infrastructure Ireland (TII) in order to mitigate the potential of development-led excavation during the construction of major road schemes.

The software requires minimal interaction and no prior user knowledge of ML techniques, significantly enhancing its accessibility to the archaeological community. The underlying ML models have been trained on an extensive archive of ALS datasets in Ireland, expertly labelled with three types of archaeological features (enclosures, ringforts, barrows). The key components of the tool include the Relief Visualization Toolbox (RVT) and the Artificial Intelligence Toolbox for Earth Observation (AiTLAS), both actively used in aerial archaeology. RVT is essential for processing input data (for training and inference) by converting digital elevation models into ML-friendly visualisations, while AiTLAS provides access to the ML models. A series of experiments has been conducted with different visualisation methods and ML architectures for object detection and semantic segmentation to determine the optimal configurations for the software.

This paper concludes the project with the ADAF tool published under open access for reuse within the research community. An evaluation of the ADAF tool will be explored through comparative analysis compared to human-only identification of archaeological features. Identification issues, such as false positives, will be discussed along with their reduction using ADAF tool functions and GIS post-processing. Finally, the retraining of the ADAF ML model will be explored for use with new ALS datasets and monument types.

12 MACHINE LEARNING AND ARCHAEOLOGICAL PREDICTIVE MODELLING: FUTURE HORIZONS IN PREDICTING THE PAST

Magnini, Luigi (Ca' Foscari University of Venice (Italy)) - Pedersoli, Stefano (University of Sassari) - Bettineschi, Cinzia (University of Augsburg)

What happens when combining two controversial digital archaeology methodologies? Which unique contributions can arise in terms of research outputs? This presentation will focus on the theoretical and practical implications of employing artificial intelligence (AI) to implement predictive models for landscape organization, and site identification.

While AI, and particularly Machine Learning (ML), stands out as one of the trendiest methodologies in the current panorama of digital applications in archaeology, it is surprising that only a limited number of case studies have explored its potential for predictive modeling. The inexplicable (?) persistence in exclusively applying ML for micromorphology identification on DTMs (did someone mention mounds?) has asphyxiated even the numerous and, potentially, infinite neurons of the most sophisticated neural network, reducing the potential of AI in archaeology to two primary research lines: feature detection and artifact analysis.

This research aims to investigate the topographical and geographical factors influencing anthropic location choices in relation to the site type and available resources. The study focuses on two classes of sites: control places in mountainous areas and nuraghes (Sardinian megalithic structures of the Bronze and early Iron Age). In the first case study, the dataset was not sufficiently large or standardized for training a neural network model, leading us to opt for a theory-driven approach combined with symbolic AI. In the second case study, the abundance of known sites enabled the development of a dedicated protocol bringing together data-driven analysis and ML. Spatial statistics were used to extract significant topographical, geological, and geomorphological variables, while CNNs were employed to pinpointing regions with the highest archaeological potential in terms of probability of finding nuraghes. The presentation

will discuss both case studies and will underline the relevance of choosing the best approach according to the type and consistency of the available dataset, and the overarching archaeological question.

13 A PICTURE IS WORTH A THOUSAND WORDS - AUTOMATED WORKFLOW OF ARCHAEOLOGICAL ILLUSTRATIONS USING DEEP LEARNING

Klein, Kevin (Vor- und frühgeschichtliche Archäologie, Institut für Altertumswissenschaften, Johannes Gutenberg University Mainz, Mainz, Germany; Palaeogenetics Group, Institute of Organismic and Molecular Evolution (iomE), Johannes Gutenberg University Mainz, Mainz, Germany) - Brami, Maxime (Palaeogenetics Group, Institute of Organismic and Molecular Evolution (iomE), Johannes Gutenberg University Mainz, Mainz, Germany) - Gorelik, Alexander (Vor- und frühgeschichtliche Archäologie, Institut für Altertumswissenschaften, Johannes Gutenberg University Mainz, Mainz, Germany) - Lämmel, Ralf (Software Languages Team, University of Koblenz, Koblenz, Germany)

The transition from Neolithic to Bronze Age societies in Europe is characterized by an enormous amount of archaeological material, including tens of thousands of graves, published to different standards. The primary challenge in analyzing and classifying these assemblages lies in the lack of easily accessible, machine-readable data. There are two potential data sources in publications: written descriptions and illustrations. Working with content from numerous publications is difficult, due to differences in written descriptions and the absence of common recording systems. Manually processing large amounts of drawings to extract information such as size or orientation of graves is a time-consuming, repetitive and error-prone task.

To facilitate the processing of large amounts of data we developed a two step workflow which is implemented in a software called AutArch (Klein et al. 2023): the first step is completely automated and utilizes neural networks for object detection and classification, image processing algorithms and OCR. The second step consists of an interactive user interface allowing for manual adjustments but also offers a toolset for data analysis.

Using AutArch, we were able to quickly identify graves in archaeological PDFs and assemble a dataset of 613 Neolithic burials. Basic attributes such as the size, orientation and number of skeletons in the burial pit were automatically extracted. Crucially, the workflow can relate attributes on the page, such as the grave outline, the north arrow and the scale, to generate archaeologically-relevant data from drawings. It can also extract and analyze whole-outline shape data using EFA.

In sum, AutArch harnesses the power of AI to deliver fast, efficient and standardized data collection from archaeological illustrations. The old maxim, 'a picture is worth a thousand words', has never been truer.

Klein, K. et al. (2023), 'An AI-assisted workflow for object detection and automated recording in archaeological catalogues'. ArXiv: 2311.17978.

14 NAMED ENTITY RECOGNITION APPLIED TO XML-TEI-ENCODED FRENCH ARCHAEOLOGICAL REPORTS. FIRST RESULTS OF THE ARCHES PROJECT

Rego, Diane (Inrap) - Menu, Ariane (Inrap) - Bryas, Emmanuelle (Inrap)

Over 2,000 archaeological field reports are produced every year at the Inrap, encompassing the whole French territory and all chronological eras. In spite of a dedicated online catalog platform (Dolia) and a permanent archiving at the CINES (French National Computer Center for Higher Education), the reports lack open accessibility and reusability due to their PDF format and the sheer volume of data they represent. Facing this situation, this paper will present ARCHES (Archéologie & Édition Structurée), a project experimenting new approaches to the field reports' publishing chain in order to FAIRify our data.

Financed with the support of the French National Fund for Open Science (Fonds National pour la Science Ouverte), ARCHES aims to explore ways of improving the dissemination and exploitation of field reports using Machine Learning and the XML-TEI format. This presentation will display the first results of the project, showing the successes and pitfalls encountered during the creation of a dedicated Named Entity Recognition model, from the annotation campaign on INCEPTION and training with the spaCy Python library to its evaluation. Building on a previous experiment made within the ARIADNEplus project, this model aims to identify fifteen types of archaeological entities, from objects and features to materials and techniques, from people and organizations to places and chronological references, and more. Then, we will explain how this model can enrich the semantic mark-up in TEI to already XML-structured archaeological reports to enhance the online publication and consultation of FAIR archaeological data.

15 FINDING A MATCH: A DIGITAL COMPARISON OF ARCHAEOLOGICAL POTTERY DRAWINGS AND MORPHOLOGICAL DATA

Zampierin, Daniele (Freie Universität Berlin) - Zampierin, Luca (Independent researcher)

From the third century BCE onwards, the Indian Ocean, particularly its Western half, has been the stage for the development of a large trade network connecting three different continents and countless different cultures. Despite being the topic of ever-growing interest from the international archaeological and historical community, the image of the Indian Ocean trade network is still extremely fragmented, isolated, and far from a comprehensive understanding of its original dynamics. Among the multiple difficulties that a researcher faces when investigating such long-distance interactions, identifying the provenance of ceramic artefacts is one of the most significant and complex.

Within the provenance study of pottery, the most adopted approaches are two: raw material analysis and morphological comparison. Despite being sometimes used independently, ideally, the two approaches should be combined to have a complete picture and a better identification. However, the combination of the two methods requires an enormous amount of data extraction and comparison resulting in an enormous investment of time and effort.

This paper introduces a new methodology, based on machine learning, which has been developed specifically to speed up the provenance study of ceramic artifacts from Khor Rori (Oman). Such methodology, built combining gradient boosting and content based image retrieval, offers the possibility of searching for morphologically comparable artefacts from a large collection of archaeological materials. In particular, the program confronts the morphological data and the archaeological pottery drawings providing the researcher with a limited set of potential matches to choose from. Consequently, the researcher is left only with the duty of choosing the most similar ceramic classes simply by comparing the material description. The presentation aims to start a discussion on the advantages and disadvantages of the adoption of machine learning in pottery provenance studies.

16 THE SHADOWS OF DIFFERENCES: NEURAL NETWORKS AND PREPROCESSING STRATEGIES IN DIGITAL ARTEFACT ANALYSIS

Blochin, Jegor (independent researcher) - Lashmanov, Oleg (independent researcher) - Korolev, Alexander (independent researcher) - Silaeva, Nina (independent researcher) - Vasilyev, Stanislav (independent researcher)

This paper explores the application of neural networks in digital archaeology, specifically focusing on artefact analysis. Over the past decade, numerous implementations have emerged, targeting artefact classification, typology analysis, and pattern recognition. Stressing the importance of high-quality preprocessing in image recognition, our team has dedicated several years to developing an algorithm for searching analogies among archaeological artefacts in diverse databases from multiple institutions. We thoroughly explore the pros and cons of different preprocessing pipelines, evaluating approaches like image matting for effective artefact segmentation in photographs containing additional objects. The paper provides a comparative analysis of different neural network types, including convolutional neural networks and transformers, for similarity detection. While these networks are generally effective, our experience highlights the necessity of additional preprocessing steps for optimal performance in archaeological tasks. Finally, drawing on practical insights, we propose a comprehensive pipeline covering detection, classification, semantic segmentation, and similarity search. The proposed approach synthesizes our team's practical experience, offering a valuable contribution to the field of machine learning in digital archaeology.

1072 CROP HISTORY RESEARCH: AFTER PREHISTORY

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Ros, Jerome (Institut des Sciences de l'Évolution de Montpellier; CNRS) - Fuks, Daniel (Ben-Gurion University of the Negev) - Ryan, Philippa (Interdisciplinary Research, Royal Botanic Gardens Kew) - Alexander, Michelle (BioArCh, Department of Archaeology, University of York) - Peña-Chocarro, Leonor (Instituto de Historia, Consejo Superior de Investigaciones Científicas (CSIC))

Session format: Regular session

Reconstructing the pathways of agricultural crop diffusion and evolution is essential to research on the origins and development of agriculture through time, with long-recognized implications for modern crop improvement and understandings of human history. Yet, until recently, research has largely focused on initial domestication beginning with the southwest Asian Neolithic over 10,000 years ago, to the near exclusion of more recent crop histories directly affecting today's agricultural diversity. This session aims to bring together a diverse group of researchers working on agricultural developments over the last 3,000 years or so, from any region. This session will look at the notions of legacies, transitions, changes and evolutions from a socio-economic and/or environmental perspective. Papers (reviews or case studies) may include archaeobotanical, ethnoarchaeological, biomolecular, isotopic, historical or other

methods of inquiry. Interdisciplinary studies are encouraged and we are particularly interested in work focused on a particular crop plant or group of crops.

ABSTRACTS

1 WILL CORDIA MYXA STAND UP, PLEASE? UNTANGLING THE HISTORIES OF CORDIA SPECIES IN THE ANCIENT EASTERN MEDITERRANEAN

Muthukumar, Sureshkumar (National University of Singapore)

The fruit stones of the edible sebesten plum (*Cordia myxa*), whose native range extends from mainland Southeast Asia to Iran, are reported present in Egyptian archaeological sites from the early Bronze Age on. The exceptionally early presence of this Asian species in Egypt remains unexplained and perplexing. Some of these fruit stones may be misidentifications of the related grey-leaved saucer berry (*Cordia sinensis*), a native of Africa and Asia. Additionally, a few other Afro-Asian *Cordia* species (e.g. *Cordia dichotoma*, *Cordia africana*) present a long history of human consumption and use. Regardless, the sebesten plum is certainly present in later Egyptian samplings, particularly those of the Greco-Roman period. This paper aims to clarify the dispersal trajectory and uses of *Cordia* species in ancient eastern Mediterranean contexts through archaeological and textual records. Using relocated *Cordia* species as an index for human mobility, the paper will also shed light on linkages between societies in East Africa, Peninsular Arabia, India, and the eastern Mediterranean.

2 ARCHAEOBOTANY, GEOMETRIC MORPHOMETRICS AND GENOMICS OF WORLDWIDE OPIUM POPPY (*PAPAVER SOMNIFERUM* L.) ACCESSIONS REVEAL ITS ORIGINS AND SPREAD

Oliveira, Hugo (Interdisciplinary Center for the Archaeology and Evolution of Human Behaviour (ICArEHB), University of Algarve, Faro, Portugal.) - Machado, Rui (Interdisciplinary Center for the Archaeology and Evolution of Human Behaviour (ICArEHB), University of Algarve, Faro, Portugal.) - Salavert, Aurélie (Unité Mixte de Recherche (UMR) Archéozoologie, Archéobotanique: Sociétés, Pratiques et Environnements, Muséum National d'Histoire Naturelle (MNHN), Centre National de Recherche Scientifique (CNRS), Alliance Sorbonne Université, Paris, France.) - Bouby, Laurent (ISEM, University of Montpellier, CNRS, IRD, EPHE, Montpellier, France.) - Soteras, Raúl (Division of Natural Sciences, German Archaeological Institute (DAI), Berlin, Germany.) - Bonhomme, Vincent (ISEM, University of Montpellier, CNRS, IRD, EPHE, Montpellier, France) - Evin, Allowen (ISEM, University of Montpellier, CNRS, IRD, EPHE, Montpellier, France) - Antolín, Ferran (Division of Natural Sciences, German Archaeological Institute (DAI), Berlin, Germany.)

Studies on the origins and spread of agriculture in the Old-World focus almost exclusively on food crops domesticated in Southwest Asia, namely cereals and pulses. Crops with multiple uses (p.ex. for fibre, oil, medicines) or those cultivated after native species from outside SW Asia have received scarce attention. The opium poppy (*Papaver somniferum* L.) was probably the only major crop domesticated in Neolithic Europe and one of a few species cultivated for various purposes (i.e. narcotic properties, medicinal, seed oil and food).

The earliest poppy remains were recovered in early Neolithic contexts in sites such as La Marmotta (Italy) and La Draga (Spain), dated to 5610–5480 cal BCE and 5311 and 4717 cal BCE, respectively. Poppy seeds are also found in many Linear Pottery Culture (LBK) sites in Central/North-Western continental Europe (5200–5000 cal BCE), out of the area of its presumed wild distribution form. This temporal proximity between poppy presence from the LBK and Cardial is intriguing. One hypothesis is that poppy was initially exploited in the Cardial and moved into the LBK region, following existing networks. The following diffusion of poppy cultivation during late prehistory and classical antiquity remains unclear.

Here, we present a combination of genomic analysis and geometric morphometry of seeds of 160 modern opium poppy accessions from Eurasia. The results are contextualised with radiocarbon dates directly obtained from archaeological poppy seeds, iconographic attestations, and textual references. From these we propose a tentative history of opium poppy diffusion and its uses in prehistory and historical times.

3 ETHNOBOTANICAL PERSPECTIVES ON CROP HISTORIES IN WEST AFRICA

Ryan, Philippa (RBG Kew)

Ethnobotany has the potential to provide new perspectives on recent and longer-term crop histories, and to link up the archaeological and historical record to the present day. Some groups of crops have been little focused on within archaeobotany, because they leave limited or difficult to interpret archaeobotanical remains (such as vegetatively propagated crops). In other instances, ethnobotany can provide ethnoarchaeological insights about crop histories in countries where there has been virtually no archaeobotany. Ethnobotany can provide new information on landrace diversity and varietal groupings and about changes in the role of crops in living memory. Recent changes in the relative

importance and uses of crops are often little documented, but provide a historical baseline from which to consider the role of local crops prior to the great changes in agrobiodiversity patterns brought about by the increased role of commercial monocrops over the last century. This paper will focus on recent ethnobotanical fieldwork in Guinea, West Africa, on yams and fonio.

4 THE CHANGING FORTUNES OF PEA IN IRELAND OVER THE LAST TWO MILLENNIA

Collins, Adam (University College Dublin) - McClatchie, Meriel (University College Dublin) - Negrão, Sónia (University College Dublin) - Vargas Sielfeld, Sofia (University College Dublin)

Current pea production in Ireland for human consumption is clustered around a single, modern pea processing plant in the east of the country. Has pea always been grown in such a small region of the country or was it different in the past? Can we see from the archaeological record how pea was grown in Ireland's past and determine what socio-economic factors influenced its use across Ireland over the past 2000 years? Ireland has a rich history of farming stretching back to the Neolithic period. While ancient Irish farmers cultivated a wide array of crop species and varieties in all areas of the country, modern farming practices have restricted the growth of certain crops to certain areas. The CRO-PREVIVE project examines the extensive archaeological evidence for farming in ancient Ireland, focusing on the trajectories of three target crops - Emmer Wheat, Rye and Pea. This mixed-methods project seeks to examine the transitions, changes and evolutions of each crop from different perspectives to seek an explanation as to why these crops are underutilised in the modern context and by working with industry specialists how we might re-introduce the crops, encouraging more sustainable farming practices and encouraging a more diverse environment for all.

5 COMPARATIVE GENETIC VARIATION IN OLD OLIVE TREES IN THE SOUTH LEVANT - A WINDOW INTO THE HISTORY OF OLIVE CULTIVATION

Barazani, Oz (Agricultural Research Organization, Institute of Plant Sciences, Israel) - Ben Dor, Elad (Agricultural Research Organization, Institute of Plant Sciences, Israel; The Robert H. Smith Faculty of Agriculture, Food and Environment, the Hebrew University of Jerusalem, Israel) - Dag, Arnon (Agricultural Research Organization, Gilat Research Center, Israel)

The olive tree (*Olea europaea*) is the most important fruit tree of the Mediterranean Basin, possessing both economic and cultural significance. The earliest evidences of olive fruits usage (table olives and oil extraction) that had been found in the southern Levant (modern Israel) indicate on the focal role of this region in olive domestication and thus on the importance of local olive genetic resources. With that in mind we study the history of olive cultivation in the southern Levant. Using molecular tools in genetic analysis of old living olive trees we detected ancient landraces and suggest on a trend in cultivar usage along history. In addition, by using comparative analysis between samples collected from the canopies and roots we were able to trace back preferable propagation technique. Our analysis included iconic olives in the garden of Gethsemane and ancient living olive trees, relicts of Byzantine agricultural system in the Negev desert. The findings contributed to the understanding of the importance of the unique germplasm that still exist in the region and initiate ex-situ and in situ conservation programs.

6 SEARCHING THE ORIGIN OF CULTIVATED OLIVES: GENETIC, MORPHOMETRIC AND PHENOTYPIC ANALYSIS OF NATURALLY GROWING OLIVES IN THE ATLIT AREA, ISRAEL

Ben Dor, Elad (The Robert H. Smith Faculty of Agriculture, Food and Environment, the Hebrew University of Jerusalem, Israel; Agricultural Research Organization, Institute of Plant Sciences, Israel) - Barazani, Oz (Agricultural Research Organization, Institute of Plant Sciences, Israel) - Dag, Arnon (Agricultural Research Organization, Gilat Research Center, Israel) - Ben Dor, Yoav (Geological Survey of Israel)

It is known that the ancestor of cultivated olives (*Olea europaea*) is its wild relative - *O. europaea* subsp. *europaea* var. *sylvestris*, yet the original gene pool of var. *sylvestris* remains unknown and whether genuine populations of the wild ancestor still exist is the subject of debate among botanists.

In this research we focused on the most hypothetical southern distribution range of var. *sylvestris* in the East Mediterranean, in a region that is less subjected to gene flow from groves of cultivated olives. In a large scale botanical survey we mapped hundreds of naturally growing olives and integrated genetic, morphometric and phenotypic analyses to create passport data set for individual trees. The variation of size and shape of stones, fruit and oil characteristics and genetic ID was immense in comparison to cultivated varieties. All together the results showed that this special population may be the key to unlocking the origins of cultivated olive trees.

7 OLIVE CROPS IN LATE BRONZE AGE CRETE: BIODIVERSITY AND TEXTUAL SOURCES

Pierini, Rachele (University of Copenhagen)

This paper focuses on the olive crops *Olea europaea* in Late Bronze Age Crete and the distinction between wild and domesticated plants by analysing the textual sources attesting the presence of olive trees on the island, namely Linear A (1800-1450 BCE) and Linear B (1450-1100 BCE) tablets. In Linear A and Linear B, 'olive' is denoted by the sign AB 122 OLIV, which is used as a plain logogram and as a ligatured sign, namely a logogram incorporating a syllabic sign that aims to further specify the typology of the logogram. The Linear B ligatured signs of AB 122 OLIV allow to distinguish between wild and domesticated olive plants. By analysing the written sources from Late Bronze Age Hagia Triada, Zakros, Tylissos, Arkhanes, and Knossos this paper also sheds light on the relevance of the geographical and chronological contexts of these findings in connection to the open questions about the exploitation of olive cultivation in Bronze Age Crete. The study also delves into the broader archaeological context, incorporating data from pollen studies, crop-processing activities, and the identification of olive taxa.

8 VITICULTURE LANDSCAPES OF THE LATE ANTIQUE SOUTHERN LEVANT

Miller, Shulamit (University of Haifa; Hebrew University of Jerusalem) - Bar-Oz, Guy (University of Haifa) - Ben-Eliyahu, Eyal (University of Haifa) - Gambash, Gil (University of Haifa)

Viticulture in the ancient Mediterranean was one of the most prolific agricultural enterprises. If properly tended, vines could grow in diverse landscapes and climate regions, providing both large- and small-scale vintners and landowners with high financial gains at relatively low initial investment.

To date, studies of viticulture in the Roman and Late Antique Mediterranean have focused primarily on the western Mediterranean, with some attention placed on the regions of Greece, Asia Minor, and most recently also Egypt. Nevertheless, the region of the Levant, particularly the southern Levant, remains for the most part outside of scholarly debate, despite rich archaeological and textual evidence attesting to diverse sustainable strategies used in growing vines. This paper attempts to bridge this gap by presenting new evidence and insights into viticultural practices in the southern Levant, with emphasis on the configuration and architecture of vineyards. By examining the landscapes, layout, and planting practices, we are able to discuss sustainable strategies evident in the methods of natural resource exploitation in the context of vineyards. For example, we address viticultural practices in the arid micro-region of the Negev Highlands, which produced prized wines traded throughout the Late Antique Mediterranean. Also, rock-cut vineyards located in hilly landscapes exemplify strategies aimed at combating soil erosion on slopes and at maximizing cultivation potential. Ultimately, despite regional differences, we show that the evidence from the southern Levant corresponds to the broader framework of viticultural tradition common throughout the Mediterranean world.

9 OLIVE FINDING FROM MA'AGAN MIKHAEL B SHIPWRECK (7TH-8TH CENTURY CE)

Schmerler, Noam (School of Archaeology & Maritime Cultures, University of Haifa, Israel) - Ben Dor, Elad (Institute of Plant Sciences, Department of Vegetables and Field Crops, Volcani research Institute, Israel; The Robert H. Smith Faculty of Agriculture, Food and Environment, Israel) - Ben Dor, Yoav (Geological Survey of Israel, Jerusalem) - Barazani, Oz (Institute of Plant Sciences, Department of Vegetables and Field Crops, Volcani research Institute, Israel) - Cvikel, Deborah (School of Archaeology & Maritime Cultures, University of Haifa, Israel)

The Ma'agan Mikhael B shipwreck was found about 30 km south of Haifa, Israel. It is the remains of a 25-meter-long merchantman which plied the Mediterranean Sea at the early Islamic period (7th-8th century CE). The shipwreck was found in pristine condition and excavated in the course of eight seasons (2016-2022). The 250 amphorae found in the hull contained different foodstuff such as dates, nuts, fish and olive fruits. This research focused on 24 out of the 36 amphorae which contained preserved olives, apparently table olives. These amphorae are a unique finding that has no precedent in this time period. Using designed computerized morphometric tools, we aim deciphering the origin of these olives and accordingly the rout of the ship. Our results show that the olives belong to cultivars typical to the southern Levant, the region of modern Israel, Palestine, Syria, and Jordan. This discovery opens new understanding on the use and trading of olives as staple food (table olives), deeply rooted in the customs of the region.

10 FIRST ARCHAEOBOTANICAL EVIDENCE FOR *V. FABA* VAR. *EQUINA* AND *VICIA FABA* VAR. MAJOR CULTIVATION AND BREEDING FROM MEDIEVAL SOUTHERN ITALY

Grasso, Anna (Università del Salento) - Primavera, Milena (Università del Salento) - Fiorentino, Girolamo (Università del Salento)

The faba bean (*Vicia faba* L.) was one of the first plants to be domesticated. The cultivation of this legume made it possible for man to have readily available a high protein food, animal fodder and a natural fertilizer for the fields. These features, along with the ease with which it could be grown and the production cycle in alternative to grains, determined its widespread use for millennia.

The circulation of the small grain fava bean started in the earliest phases of domestication and its size remained essentially the same for thousands of years. However, beginning in the Late Antiquity, there was an increase in the size of the bean, witnessed by some remains identified in the Mediterranean and Central Asia, which led to the *Vicia faba* var. *equina* in Sicily (Italy). Subsequently, in the later Middle Ages, there was a new phase of varietal improvement of the bean in Apulia (Italy) that led to a new faba cultivar, the *Vicia faba* var. *major*.

The purpose of this study is to substantiate this picture, with reference to the morphometric analysis of charred remains of *Vicia faba* specimens collected from various archaeological sites located in south-east Italy, dated to a range of periods, comparing them to modern reference material.

11 THE ROMAN WAY(S). ARCHAEOBOTANICAL RECORDS DOCUMENT DIFFERENCES IN CROP CHOICES IN WESTERN IBERIA DURING ROMAN TIMES

Tereso, João (CIBIO-BIOPOLIS - Research Center In Biodiversity and Genetic Resources/University of Porto; Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon; Centre of Interdisciplinary Studies, University of Coimbra; MHNC - UP - Natural History and Science Museum of the University of Porto) - Seabra, Luís (CIBIO-BIOPOLIS - Research Center In Biodiversity and Genetic Resources/University of Porto; Faculty of Sciences, University of Porto) - Guerra, Amílcar (Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon) - Arruda, Ana (Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon) - Fabião, Carlos (Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon) - Viegas, Catarina (Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon) - Detry, Cleia (Centre for Archaeology. UNIARQ. School of Arts and Humanities. University of Lisbon) - Carvalho, Pedro (Centre of Interdisciplinary Studies, Faculty of Arts and Humanities. University of Coimbra) - Silva, Ricardo (Centre of Interdisciplinary Studies, Faculty of Arts and Humanities. University of Coimbra) - Correia, Virgílio (Museu Nacional de Conimbriga; Centro de Estudos Clássicos e Humanísticos, Universidade de Coimbra)

Until recently, most Roman carpological investigation conducted in Iberia has focused on the South, East and NW areas, namely in the Tarraconensis and Baetica provinces. B-Roman project aimed to tackle the lack of archaeobotanical studies in the Lusitania province by recovering and analysing a large number of samples from several archaeological sites in western Iberia. The aim of this paper is to present and discuss its main results.

Data obtained suggests a greater reliance on a variety of fruits absent or rare in the Iron Age and show a close affinity between Lusitania and Mediterranean Hispanic provinces, rather than with the NW. Despite some investigation and preservation biases affecting the archaeobotanical record, differences in the western fringe are probably driven by south-north environmental contrasts, although social-economic causes are likely also at play.

This interplay between crop choices, environmental constraints, and the introduction of social and economic models under the Romans in western Iberia will be explored using the carpological data as a starting point but integrating other components of the archaeological record in order to put the archaeobotanical information into perspective.

12 SOWING THE SEEDS OF EMPIRE: EARLY STATECRAFT AND THE EMERGENCE OF INDIGENOUS AGRICULTURE ON THE MONGOLIAN STEPPE (C.250 BC-150 AD)

Carolus, Christina (Yale University) - Cameron, Asa (Yale University) - Wright, Joshua (University of Aberdeen) - Honeychurch, William (Yale University) - Chunag, Amartuvshin (National University of Mongolia) - Szpak, Paul (Trent University)

The end of the first millennium BC (c.250 BC-150 AD) marks the genesis of the Xiongnu, eastern Eurasia's first nomadic state, which emerged from central Mongolia to successfully integrate one of the largest-scale political configurations in prehistory. This transformative period also marks the appearance of Mongolia's earliest direct agricultural evidence. Though long assumed to be a "purely pastoral" state, scholars have recently considered connections between these phenomena. Growing evidence suggests a political culture that may have deployed novel foodways in statecraft: namely, the development of flexible indigenous agropastoral systems that integrated or intensified production of foreign cereals. Evaluation of this perspective, however, has been hindered by a historical lack of systematic archaeobotanical analysis from sites of this period. Here we present an overview of current evidence for eastern steppe populations' relationships to agricultural practices and products during the first millennium BC. We then report results of the first and earliest formal macrobotanical and isotopic analyses ($\delta^{13}C$, $\delta^{15}N$, $87Sr/86Sr$) of a set of locally produced crop assemblages from Iron Age Mongolia, including the earliest direct evidence for the presence of wheat, barley, oats and broomcorn millet. These results are discussed in relation to previously published isotopic data from contemporaneous local human and herd animal populations as well as new GIS-based landscape analyses. Results are drawn together to situate agricultural trajectories in the Mongolian steppe within the broader prehistory of the trans-Eurasian crop exchange.

1076 THE LATE ANTIQUE TO EARLY MEDIEVAL TRANSITION IN EUROPE AND NORTH AFRICA: SOCIO-CULTURAL DYNAMICS OF MIGRATION, MOBILITY, AND IDENTITY

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Morgan, Reed (Max Planck Institute for Evolutionary Anthropology, Department of Archaeogenetics; Harvard University, Department of History) - Gerling, Claudia (University of Basel) - Olalde, Iñigo (Universidad del País Vasco) - Villalba, Vanessa (Max Planck Institute for Evolutionary Anthropology, Department of Archaeogenetics Institute of Evolutionary Biology; CSIC-Universitat Pompeu Fabra)

Session format: Regular session

The period spanning the 4th to the 9th centuries AD in the former territories of the Roman Empire and its neighbouring regions witnessed intensified human mobility, social interactions, and cultural transformations. Until recently, archaeological research related to this period has been strongly dominated by migration (or invasion) narratives and ethnic- or religious-based explanatory models, in which the Roman-Barbarian, Latin-Byzantine, and Christian-Islamic dichotomies were the main drivers for exploring and interpreting the data. The recent expansion of bioarchaeological studies, encompassing physical anthropology, isotope analyses, genetics (etc.), has facilitated multidisciplinary research, offering insights into the intricate dynamics of mobility and identity. An increasing number of research projects integrate bioarchaeological analyses with archaeological datasets and illuminate the complexity of human mobility and networks at various scales, as well as varied dynamics of interactions between non-local settlers and indigenous populations, during the Late Antique-Early Medieval transition period. In order to get an overview of recent advances in the investigation of Late Antique-Early Medieval transition, this session aims to bring together experts who combine a variety of methodological approaches such as isotope and aDNA analyses, radiocarbon dating, climate modelling etc. We encourage presentations on archaeological contexts from the former territories of the Roman Empire and its bordering regions, and are interested in diachronic studies that particularly target the transition from the Late Antiquity to the Early Middle Ages. In this framework, special attention is paid to border regions and their hinterlands, which are particularly sensitive to changes in cultural, economic, and political settings due to their geopolitical situation. However, comparisons with core areas of Late Antique and Early Medieval administrative entities are also welcome. Additional session organisers are M. Depaermentier, Vilnius University, Lithuania, and Z. Hofmanová, Max Planck Institute for Evolutionary Anthropology, Germany.

ABSTRACTS

1 TRACING THE ORIGINS OF ALWA: ISOTOPIC INSIGHTS INTO THE FOUNDATION OF SOBA AND THE SOCIO-CULTURAL DYNAMICS OF EARLY MEDIEVAL NUBIA

Ciesielska, Joanna (Faculty of Oriental Studies / Institute for Advanced Studies, Faculty of Physics, University of Warsaw)

By the mid-sixth century AD the territory of modern Sudan was divided between three kingdoms of Nobadia, Makuria and Alwa. The emergence of the medieval city of Soba, the illustrious capital of the southernmost Kingdom of Alwa (6th-15th c. CE), as a major urban settlement in the late post-Meroitic period marked the beginning of a millennium-long history. Scientific explorations in the late 20th century revealed the city's exceptional status, with extensive ecclesiastical complexes, churches, and affluent material culture. Positioned strategically at the confluence of the White and Blue Niles, Soba became a melting pot of diverse populations and a key hub in regional trade networks. While some scholars propose that the initial settlers may have been remnants of the late Meroitic kingdom, others suggest shared ancestry with the founders of neighbouring states, Nobadia and Makuria, possibly originating from the Nuba people in the Kordofan region to the south and southwest of Soba. This presentation explores the application of isotopic research to uncover the social dynamics at the foundation of the medieval metropolis. We applied isotopic analyses to investigate the origins of the people buried at various locations within the city and their concomitant ways of life. Through stable isotope analysis of human skeletal remains, we investigated dietary practices, mobility patterns, and social stratification, while animal remains provide insights into urban economic structures, including subsistence strategies, livestock management and trade networks. Despite no evidence of occupation pre-dating the foundation of the city in 6th c., the obtained results speak not only to local roots of city's inhabitants, but also to the economic reliance on enduring agro-pastoral symbiosis. This presentation explores the application of isotopic research weaving together a rich tapestry of multidisciplinary approaches to unveil the social dynamics and economic intricacies that marked the inception of this medieval African metropolis.

2 ARCHAEOGENETICS AND THE SOCIAL DYNAMICS OF ANCESTRY AND IDENTITY IN VANDAL AND BYZANTINE CARTHAGE, TUNISIA

Morgan, Reed (Harvard University; Max Planck Institute for Evolutionary Anthropology) - Chalhouni, Najd (Institut National du Patrimoine, Tunisia) - ben Romdhane, Hamden (Institut National du Patrimoine, Tunisia) - Bockmann, Ralf (University of Hamburg) - Stevens, Susan (Randolph College) - Rossiter, Jeremy (University of Alberta) - Humphrey, John (Journal of Roman Archaeology) - Pennefather-O'Brien, Elizabeth (Medicine Hat College) - Ringbauer, Harald (Max Planck Institute for Evolutionary Anthropology) - Krause, Johannes (Max Planck Institute for Evolutionary Anthropology)

The early medieval history of Carthage saw the western Mediterranean's second largest city change hands numerous times, between Vandals, Byzantines, and ultimately Arabs. Up to the time of its destruction, it remained a vital port at the centre of Mediterranean trade routes, and historical sources portray it as a vivid hub of cosmopolitan activity. Carthage was a crucible of encounter for a wide array of cultural, linguistic, and religious groups: Romans, Vandals, Berbers, and Eastern Mediterranean populations; Latin speakers, Greek speakers, and speakers of indigenous North African languages; Orthodox, Donatist, and Arian Christians. Up until now, North Africa has remained a major lacuna on the map of ancient DNA research, and bioarchaeological research more generally. Here, a new collaboration between historians, archaeologists, and archaeogeneticists aims to examine biological ancestry and kinship patterns in light of our current understanding of social identities in the early medieval city. We present new archaeogenetic results from more than 200 fifth- to seventh-century burials, representing a wide range of social identities from around the city, including extramural cemeteries, intramural cemeteries, elaborate basilicas, and isolated burials. This paper will present a first attempt to integrate the new genetic insights into migration, ancestry, demography, and kinship in early medieval Carthage together with the longstanding historiography of identity formation in post-Roman North Africa.

3 BIRTH OF A MEDITERRANEAN CITY: EXPLORING THE METAMORPHOSIS OF VALENCIA THROUGH TIME USING ANCIENT DNA

Oteo Garcia, Gonzalo (Sapienza - Università di Roma; Stockholm University (CPG))

Of all places in the Mediterranean, Iberia was probably the New World of the Old World. Coastal areas harboured Greek and Punic colonies for trade but beyond, the hinterland was an ignotous territory and the peninsula known to the wider Mediterranean as a source of metals, this caught the attention of Greeks, Phoenicians, Carthage and Rome who fought for control over its resources. This was the context in which the Romans started founding colonies that in many cases replaced indigenous settlements and transformed the land into a Hispania completely integrated in the Mediterranean sphere. Some of these early Roman sites have survived to our times, such is the case of the city of Valencia (Spain), founded in 138 BCE at the mouth of river Turia on an islet surrounded by marshes.

A new CIVIS3i-funded project starting in 2024 will study the population dynamics behind the foundation of the city and the influences by the various subsequent cultures that shaped it. Over 200 burials have been successfully sampled. The collected dataset encompasses the Roman Republican, Imperial, Visigothic and Islamic medieval periods. The collection is currently undergoing analysis to recover ancient DNA from all the remains. The genomic information will be complemented by stable isotopes and sedimentary DNA recovered from the marshes around the city to try to link changes in diet and the environment with changes in the genetic profile of the population of the city at different times.

At EAA we will be presenting the first preliminary sequencing results from the ancient genomes that cover the early history of Valentia (2nd century BCE to 7th century CE) and various archaeological sites of the city, including the foundational republican-era necropolis, tombs from the imperial-era and a cemetery associated to the Visigothic elite and ruling families in the city.

4 THE DEMOGRAPHIC IMPACT OF THE ROMAN AND VISIGOTHIC PRESENCE IN THE IBERIAN PENINSULA

Carrion, Pablo (Institut de Biología Evolutiva (CSIC-UPF)) - Olalde, Iñigo (BIOMICs Research Group, Department of Zoology and Animal Cell Biology, University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain) - Jiménez-Arenas, Juan Manuel (Departamento de Prehistoria y Arqueología, Universidad de Granada) - Vergès, Josep Maria (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Tarragona, Spain.) - Cuadrado, Miguel Angel (Museo de Guadalajara, Guadalajara, España) - Heras-Mora, Javier (Archaeological Museum of Badajoz, Junta de Extremadura, Badajoz, Spain) - García-Entero, Virginia (Departamento de Prehistoria y Arqueología, Universidad Nacional de Educación a Distancia) - Coromina, Neus (Universitat de Girona) - Lalueza-Fox, Carles (Natural Sciences Museum of Barcelona (MCNB), Barcelona, Spain) - Reich, David (Department of Human Evolutionary Biology, Harvard University, Cambridge, MA, USA.)

The transformation of the political landscape in West Eurasia can be attributed to the Roman Empire, the decline of its Western segment, and the consequential Great Migration era. The influence of these events on the demographic composition of various regions, such as the Iberian Peninsula, remains not fully elucidated. We have collected genome-wide data from 255 newly reported ancient individuals from Iberia spanning from the Roman era to the Great Migration period. The Roman presence in the peninsula dates back to the 3rd century BCE and was fully annexed by the 1st century BCE. It remained intricately connected with the broader Mediterranean through Roman roads and sea routes until its collapse in the 5th century. Our findings reveal that the populations in Roman-period Iberia were as diverse as those in other central and western Mediterranean regions, like central Italy (Antonio et al. 2019) and the Danubian frontier (Olalde & Carrion et al. 2023). Historical records indicate the impact of various groups on Iberia in the 5th century, including Germanic tribes (Buri, Suevi, Vandals & Visigoths) and Sarmatian people (Alans). While some, like the Suevi, established kingdoms, the Visigoths formed the most significant Germanic kingdom in the late 5th century, persisting until the Umayyad conquest in the 8th century. Despite the identification of individuals with Germanic ancestry at specific sites, overall, we observe a remarkable degree of population continuity in Roman-period Iberian populations. Thus, indicating limited demographic changes during this era. The close interconnections of these Germanic groups are evident in the discovery of close relatives at distant archaeological sites.

5 THE GENOMIC HISTORY OF THE BALEARIC ISLANDS

Villalba-Mouco, Vanessa (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; Institute of Evolutionary Biology, CSIC-Universitat Pompeu Fabra, Barcelona, Spain; Max Planck Harvard Research Center for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany) - Sintés, Elena (Independent researcher) - Rohrlach, Adam (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; School of Mathematical Sciences, University of Adelaide, Adelaide, South Australia, Australia) - Mas Florit, Catalina (Equip de Recerca Arqueològica i Arqueomètrica de la Universitat de Barcelona (ERAAUB); Institut d'Arqueologia de la Universitat de Barcelona (IAUB); Universitat de Barcelona (UB), c/ Montalegre 6-8, 08001 Barcelona, Spain) - Cau-Ontiveros, Miguel (ICREA, Pg. Lluís Companys 23, 08010 Barcelona, Spain; Equip de Recerca Arqueològica i Arqueomètrica de la Universitat de Barcelona (ERAAUB); Institut d'Arqueologia de la Universitat de Barcelona (IAUB); Universitat de Barcelona (UB), c/ Montalegre 6-8, 08001 Barcelona, Spain) - Skourtanioti, Eirini (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; Max Planck Harvard Research Center for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany) - Stockhammer, Phillip (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; Max Planck Harvard Research Center for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany; Institute for Pre- and Protohistoric Archaeology and Archaeology of the Roman Provinces, Ludwig Maximilian University, Munich, Germany) - Haak, Wolfgang (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany) - Risch, Roberto (Department of Prehistory, Universitat Autònoma de Barcelona, Barcelona, Spain) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Deutscher Platz 6, 04103 Leipzig, Germany; Max Planck Harvard Research Center for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany)

The Balearic Islands, located in the western part of the Mediterranean Sea, had a rich prehistory and history since the first colonization ~2500 BCE. Later, the islands underwent a distinct dynamic compared to that observed on the European mainland, especially during Late Antiquity, including periods of Vandal and Byzantine occupation. The Balearic Islands became part of Al-Andalus two centuries later than the Iberian Peninsula, and its Islamic rule lasted until the 13th century AD when the Kings Jaume I and Alfonso III of Aragón conquered the islands.

To study the population dynamics associated with the historical changes of this insular setting, we generated genome-wide data from 300 new individuals spanning 3,000 years of history. Our results show that the initial settlers of the Archipelago were genetically similar to the Beaker groups in Western Europe and Iberia. This genetic profile

persisted until the Iron Age. The introduction of central Mediterranean and North African-related ancestries to the Archipelago occurred during the Carthaginian/Punic dominance. However, the most significant genetic shift took place during Roman times, marked by the arrival of genetic ancestries from the Near East and North Africa. In Late Antiquity, we observe increased mobility, with outlier individuals displaying diverse ancestries from mainland North/Central Europe, Northeast Asia, and North Africa. The onset of Islamic domination in the Archipelago coincided with the introduction of West African ancestry in Menorca. Excess North African ancestry was found in individuals buried in Islamic, but not in Mozarab contexts. Finally, the “Christianization” of the Archipelago correlated with a decrease in North African and Near-Eastern ancestries, attributed to the arrival of contemporary groups from Northeastern Iberia.

Our comprehensive study intertwines archaeology, history, and genetics providing a holistic view of the interplay between human populations and historical transitions in the Balearic Archipelago over 3000 years.

6 FROM WINE EXPORT HUB TO PILGRIMAGE CORRIDOR: MITZPE SHIVTA AND SOCIO-ECONOMIC SHIFTS IN THE LATE ANTIQUE NEGEV DESERT

Lehnig, Sina (University of Haifa; Minerva Stiftung für die Forschung, Max-Planck-Gesellschaft)

At a first glance, Mitzpe Shivta in the northern Negev Desert is located in an arid, sparsely populated region. Yet satellite images reveal the remains of thousands of agricultural structures that bear witness to a period between the 4th and 6th centuries CE when the Negev experienced an unprecedented economic and demographic heyday. Mitzpe Shivta was embedded in this thriving agricultural landscape. Positioned on a hilltop and surrounding slopes, the site boasts a perimeter wall, towers, a church, a chapel, domestic units, a large cistern, and numerous rock-hewn rooms adorned with inscriptions and cross paintings.

Our research, encompassing inscriptions, radiocarbon dates, and pottery, indicates occupation of Mitzpe Shivta from the 6th to 8th centuries CE, spanning the Middle Byzantine to Early Islamic periods. The Middle Byzantine era (450-550 CE) witnessed regional prosperity fueled by the Mediterranean-wide export of locally produced wine, notably in Gaza Jars. However, the Justinian Plague around 541 CE precipitated a decline in wine exports. By 620 CE, Akaba Jars signalled Arab influence from the south, yet pilgrim inscriptions suggest a surge in Mitzpe Shivta's economy due to Christian tourism to St. Catherine Monastery at Mount Sinai.

Concurrently, Mitzpe Shivta's rise coincided with the gradual abandonment of the nearby Byzantine settlement of Shivta, evident in sealed doors and deserted buildings. Our project, placed at University of Haifa, aims to unravel the correlation between Mitzpe Shivta's ascendance and Shivta's decline, exploring shifts in settlement patterns from affluent villages to fortified hilltop settlements which become apparent Mediterranean wide during the 6th century. We will delve into the economic roles of monasticism and pilgrimage amid dwindling agriculture. Utilizing bioarchaeological methods, micro-geoarchaeology, epigraphy, and SfM, we seek to illuminate Mitzpe Shivta's occupation history and economic framework, offering insights into Negev settlement dynamics during periods of socio-economic upheaval and cultural change.

7 BASEL IN THE FIRST CENTURIES AD: INTERDISCIPLINARY INSIGHTS INTO MOBILITY AND SOCIO-CULTURAL STRUCTURES

Gerling, Claudia (University of Basel) - Depaermentier, Margaux (Vilnius University) - Alder, Cornelia (University of Basel) - Hajdas, Irka (ETH Zurich) - Kempf, Michael (University of Basel) - Hofmanová, Zuzana (Max Planck Institute for Evolutionary Anthropology) - Schwarz, Peter-Andrew (University of Basel)

Basel (Switzerland) played an important role in Late Antiquity and the Early Middle Ages due to its location at the margins of multiple socio-cultural entities and influences. It became a melting pot of political, cultural and economic interactions, integrating large-scale and local exchange networks. In the framework of a SNSF-funded project, we analyse various burial sites in Basel dating to the 4th-8th centuries AD using archaeological, anthropological, isotope and aDNA analysis, radiocarbon dating as well as environmental multicomponent modelling. Our aim is to provide new interpretations of human mobility, social structures and lifestyles at the periphery of the late West Roman administrative boundaries and to propose local mobility, subsistence strategies and communication networks beyond traditional migration narratives and ethnic categorisations. The project started with a pilot study on the Basel-Waisenhaus grave group, where we were able to revise the traditional idea of a strict separation between “Romans” and immigrated “Alamans” by the river Rhine.

8 COMMUNICATION AND CONNECTIVITY IN 6TH-CENTURY PANNONIA: SIGNS OF AN ETHNOGENESIS?

Koncz, István (Eötvös Loránd University) - Tian, Yijie (Department of Ecology and Evolution, Stony Brook University) - Knipper, Corina (Curt-Engelhorn-Zentrum Archäometrie) - Faragó, Norbert (Institute of Archaeological Sciences, Eötvös Loránd University) - Szeniczey, Tamás (Department of Biological Anthropology, Eötvös Loránd University) - Vyas, Deven (Department of Ecology and Evolution, Stony Brook University) - Vida, Tivadar (Institute of Archaeological Sciences, Eötvös Loránd University) - Veeramah, Krishna (Department of Ecology and Evolution, Stony Brook University) - Geary, Patrick (Institute for Advanced Study)

For long archaeological research, when describing early Medieval European societies, focused on trying to identify cultural/ethnic groups or various social classes. While this approach has come under intense criticism in the last decades, its results still form the basis of our understanding of the period and its communities. Recent developments in the archaeology of identity and the integration of bioarchaeological methods in fine-scale studies shifted the focus of archaeological research towards a series of new questions, but also gave us a chance to revisit old ones.

The comprehensive analysis of five cemeteries from the 6th-century Little Hungarian Plain (LHP), NW Hungary and SW Slovakia, provides a great opportunity to study not only the formation and development of individual communities, but also their connections and relationship in a well-defined region. LHP became one of the core territories of the Langobard polity in Pannonia as early as the beginning of the 6th century. Mortuary data indicate a stratified society with communities that integrated individuals of various cultural and social backgrounds. Isotopic evidence suggests that individual and group mobility played an important role in their formation. Paleogenomic analysis identified biologically related groups in all communities, and it also found genetic connections between sites.

In the middle of the 6th century, we witness the appearance of locally developed artefact types that spread rapidly in wider areas suggesting well-developed communication networks. This coincides with the appearance of precious metals, belt sets and second animal style in male burials suggesting the emergence of a warrior elite that will rise to its true importance later in Italy.

The combination of archaeological, paleogenomic and isotopic data suggests that LHP was part of intensive intra- and extraregional networks which could be interpreted both the cause and the consequence of the formation of a common identity in the region.

9 ON THE WAY FROM ITALY TO GOTLAND - THE FINDS OF OSTROGOTHIC SOLIDI FROM POLISH BARBARICUM

Zapolska, Anna (University of Warsaw) - Dymowski, Arkadiusz (Independent Scholar)

The Ostrogothic coins found in present-day Poland are sporadic, yet their undeniable presence is noted. Research on these coins is impeded by the fact that many artefacts, especially those from Pomerania and East Prussia, have found their way into collections of German museums and subsequently, due to World War II, have either gone missing or been dispersed. Consequently, information regarding these artefacts primarily derives from literature and only one comes from the latest discoveries.

Among the Roman solidi minted in Roman mints under Ostrogothic control found in the territory of present-day Poland, there are specimens originating from individual finds, such as the solidus from Darłowo in Pomerania, while others come from hoards. Some of these coins could have been produced in Ravenna during the reign of Theodoric I or could be imitations made on Gotland.

The analysis of these coins – die studies made with the use of AI, but also studying them in the context of other artefacts, settlement sites, and cemeteries will help answer questions regarding the reasons and circumstances of the influx of these coins into the areas of Pomerania, Kuyavia, and Greater Poland. Additionally, it will shed light on whether we are dealing with the migration of small groups of people from Scandinavia to the southern Baltic coast, the “transit” of Scandinavian mercenaries through Polish lands towards Italy (and back), or the existence of a network of trade and/or political connections among Germanic tribes in Late Antiquity in Europe.

EARLY MEDIEVAL POPULATION MOVEMENTS FROM THE STEPPE INTO EUROPE: INTEGRATING ARCHAEOLOGY, HISTORY AND ANCIENT GENOMICS

Gnecchi Ruscone, Guido Alberto (Max Planck Institute for Evolutionary Anthropology 04103, Leipzig, Germany; Department of Archaeology and Museology, Faculty of Arts, Masaryk University, 60200, Brno, Czechia) - Rácz, Zsófia (Institute of Archaeological Sciences, ELTE - Eötvös Loránd University, 1088, Budapest, Hungary) - Traverso, Luca (Max Planck Institute for Evolutionary Anthropology 04103, Leipzig, Germany) - Liccardo, Salvatore (Department of History, Universitätsring 1, 1010 Wien; Institute for Medieval Research, Austrian Academy of Sciences, Ignaz-Seipel-Platz 2, 1010 Wien) - Pohl, Walter (Department of History, Universitätsring 1, 1010 Wien; Institute for Medieval Research, Austrian Academy of Sciences, Ignaz-Seipel-Platz 2, 1010 Wien) - Vida, Tivadar (Institute of Archaeological Sciences, ELTE - Eötvös Loránd University, 1088, Budapest, Hungary; Institute of Archaeology, HUN-REN Research Centre for the Humanities, 1097, Budapest, Hungary) - Krause, Johannes (Max Planck Institute for Evolutionary Anthropology 04103, Leipzig, Germany) - Hofmanová, Zuzana (Max Planck Institute for Evolutionary Anthropology 04103, Leipzig, Germany; Department of Archaeology and Museology, Faculty of Arts, Masaryk University, 60200, Brno, Czechia)

Recent genomic studies showed that during the Migration Period and the Early Middle Ages, people carrying Central or East Asian ancestries appeared in Europe at different in multiple waves. The earliest genomic evidences involve only a handful of individuals from the 5th century CE. Chronologically, this corresponds to the Hunnic period when over only a few decades several raids into the former territory of the Roman Empire of the Hun group of steppe riders have been recorded. Nevertheless, only a limited archaeological record presenting eastern or central Asian Steppe connections have been found for this time period. The scarcity of the genomic and archaeological evidences leaves open the questions on what was the actual impact of large-scale migrations from the steppe, from where and what role migration had in shaping populations' cultural identity within the Hunnic empire. Around a century later, in the late 6th century CE, another, this time substantial, influx of people carrying East Asian or admixed ancestries appear in the Carpathian Basin. This coincides with the historical accounts of the arrival in 568 CE of the Avar people who settled in the Carpathian Basin within a large territory that included the former Roman province of Pannonia, establishing their "Qaganate" (i.e. empire) that lasted over 250 years. Alongside historical accounts, the Avar period left an abundant and culturally diverse archaeological record testifying trans-Eurasian connections.

Combining new and published genomic data with archaeological and historical contextualization, we: 1) investigate the impact of these movements from the steppe in Early Medieval Europe; 2) test possible geographic origins following the main historical and archaeological hypotheses discussed in modern scholarly debates, using comparative ancient genomic data available from preceding and coeval contexts across the Eurasian Steppe.

1077 RESEARCH DATA MANAGEMENT IN THE FIELD

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Riebschläger, Fabian (German Archaeological Institute; NFDI4Objects) - Novák, David (Institute of Archaeology of the Czech Academy of Science, Prague)

Session format: Regular session

Gathering, curating and storing research data during field work is not a trivial task. In fact, it can quickly get messy. Archaeologists often have to deal with less-than ideal working conditions and heterogeneous research methods and diverse documentation requirements. On top of that, projects often involve specialists from different disciplines, such as the natural sciences, who bring their own requirements and practices to the table.

This often leads to data silos that have to be subsequently integrated. At the same time, the demands on research data management and data quality have continuously risen in recent years. Institutions that fund research expect professional data management. Compliance with the FAIR principles is a mandatory requirement. This increases time and effort required by researchers and, in some cases, demands new technical skills that are not reflected in today's educational curricula.

Against this backdrop, many research projects have developed their own workflows and best practices to enable high-quality documentation with minimised effort. Initiatives such as the National Research Data Infrastructure for Objects (NFDI4O) in Germany are trying to bring the community together to transfer these project-specific specifications into commonly accepted standards and best practices.

In our session we aim to discuss these workflows and best practices developed in projects to improve our understanding of practical research data management in the context of field research. We invite contributions that deal with the entire documentation process or specific aspects. These include, but are not limited to:

- Workflows & Tools: from data collection in the field to FAIR data
- Best Practices: data formats and standards you use

- AI / Machine learning for data processing and/or quality management
- Working with silos: transformation and publication of data
- Reuse Open Data: from BigData to ML/AI Application
- Projekt specific excavation manuals and data models.

ABSTRACTS

1 FROM FIELD TO FAIR: DATA WORKFLOW AT THE AUSTRIAN ARCHAEOLOGICAL INSTITUTE (OEAI)

Schwaiger, Helmut (Austrian Archaeological Institute) - Burkhart, Karl (Austrian Archaeological Institute) - Danthine, Brigit (Austrian Archaeological Institute) - Welte, Micheline (Austrian Archaeological Institute) - Baudouin, Elise (Austrian Archaeological Institute) - Hye, Simon (Austrian Archaeological Institute)

As the largest archaeological research institute in Austria with a wide variety of projects and documentation types, it was essential for the OeAI to develop a common strategy for dealing with research data. Free and open-source software is used in the field wherever possible to enable interoperability. For example, field projects, such as the Ephesos excavation or the 'Crossing the Seas' survey project use QGIS with the Tachy2GIS or QField interface. To make data exchange with restoration or ceramic processing easier and less error-prone, the data is regularly compared with the Axiell Collections object database. Additionally, data from other infrastructure and research units is also integrated, such as photo documentation, using predefined forms.

Care is taken to ensure FAIR data, not only for long-term archiving but also for other projects and applications. For this it is important that both controlled vocabularies and structured data models are used that can build on one another. Special core services have been set up at the OeAI for this purpose, such as OeAI.DAM, the central contact point for images and other digital assets. Specific interfaces have been programmed into other projects so that data can be available and exchanged without redundancy.

2 DEVELOPING SOFTWARE FOR THE DOCUMENTATION OF ARCHAEOLOGICAL FIELDWORK IN NFDI4OBJECTS

Riebschläger, Fabian (German Archaeological Institute; NFDI4Objects) - Kleinke, Thomas (Verbundzentrale des GBV (VZG); German Archaeological Institute; NFDI4Objects)

Archaeological field research is very heterogeneous, encompassing methods like excavations, surveys, and building recordings. Documentation requirements vary greatly across archaeological disciplines and the regional heritage agencies. In addition, the recorded data from numerous specialist disciplines involved, for example from natural science, have to be integrated. User requirements for software to document field research are also diverse. Input workflows should be intuitive. The navigation of the data should support analysis and interpretation. In addition, the security and integrity of the data should of course be guaranteed. And finally, the data should be as easy as possible to export in an appropriate form for publication and long-term archiving.

In its search for suitable software to document its field projects and to replace the its old system, the German Archaeological Institute (DAI) defined a number of requirements that were considered particularly important:

- A sufficiently flexible, adaptable data model.
- A standardized core data schema for data comparison across geographical, temporal and thematic boundaries.
- Multilingual data entry.
- Offline and online functionality with robust data synchronization.
- Effortless publication of primary research data in accordance with the requirements of the international research community and the funding providers.
- The exclusive use of open source software.

As no suitable software was found, the decision was made to design one from scratch. The focus was on enabling complete documentation of archaeological fieldwork, supporting existing workflows, and improving them through the use of customised digital technologies. This distinguishes Field from generic platforms, such as GIS or CAD.

The individual roles of the software were split into separate components: a desktop application for on-site data entry, a server component for synchronisation via the Internet and a dynamic publishing platform. The software is now being further developed together with the community within NFDI4Objects.

3 THE MILESIAN APPROACH IN CONTEXT: ORGANIZING A DATA CENTRIC WORKFLOW BETWEEN FIELD AND FIND PROCESSING

Steinmann, Lisa (Universität Hamburg) - Sliwka, Fabian (Universität Hamburg) - Huy, Sabine (Christian-Albrechts-Universität zu Kiel)

Large and diverse research hubs such as the Miletus Excavation need to take a normative and unifying approach to data management across multiple concurrent projects. The first publication of the Miletus Documentation Manual in 2021 (DOI: 10.25592/uhhfdm.11389) establishes a modular workflow for the different work areas and projects in Miletus. The Manual sets transparent guidelines for systematic documentation and collaboration, as well as data quality and storage.

The new documentation system relies on a highly customized idai.field-database, which all researchers use for data collection. Custom tools supplement this workflow: Mainly milQuant, an intuitive app that synchronizes with the database to provide quantitative visualizations without demanding technical expertise from its users. Our approach enables and promotes swift collaboration and data flow between a diverse group of researchers representing the full spectrum of different archaeological disciplines and methods.

Due to its hierarchical data model, idai.field inherently integrates data generated in the numerous work areas of an archaeological excavation. However, the default configuration lacks a specific module for the immediate communication of observations between field and find processing right when and where it is needed: during the excavation itself. To bridge this gap, we established the 'First Impression'-form that allows researchers from both areas to share notes on intermediate results with their respective counterparts in an immediate and efficient manner. milQuant completes this qualitative approach as a quantitative tool, combining data from both field and depot to generate conclusive information packages for further analysis. Furthermore, it has proven to be a quick and powerful tool for quality control of newly collected data on site.

In our presentation, we will showcase the systematic workflow and collaboration between field and depot, using case studies from recent excavations in Miletus with reference to the Documentation Manual.

4 CURATING DIGITAL ARCHIVES: DATA MANAGEMENT AND STANDARDISATION

Green, Katie (University of York) - Zoldoske, Teagan (University of York)

The archaeological intervention done in advance of building a new high speed rail line connecting the North and South of England is one of the largest in UK history. While the High Speed 2 (HS2) project has created a wealth of new information, before any of that information can be disseminated to the general public it must first be properly collected, documented, and linked. To this end, effective data management is vital and should be in place before data collection has begun. It is integral to facilitate effective data collection and dissemination while keeping it FAIR - Findable, Accessible, Interoperable and Reusable - in order to achieve the greatest public value for an archive.

From the beginning of the project HS2 created technical specifications. These technical specifications aimed to standardise data collection processes, facilitating both data utilisation by HS2 and its transfer to the Archaeology Data Service (ADS), the digital repository responsible for the long-term curation of the dataset. However, not all facets of archaeological data collection were confined by strict technical specifications in order to allow contractors to employ their own systems and methodologies. This paper will examine the implementation of technical specifications by the HS2 project on the ADS workflows. It will discuss how, when detailed standardisation was specified and data was approved by HS2 before deposit it resulted in greater uniformity in the data. It will then compare this with instances where data had less stringent control, necessitating greater processing time by the ADS to optimise dissemination and to ensure data remained FAIR. The paper will conclude by reflecting on HS2's data management practices and their potential application to projects both large and small.

5 COMBINING FLEXIBILITY AND STANDARDISATION IN BORN-DIGITAL FIELD RECORDING

Indgjerd, Hallvard (Museum of Cultural History University of Oslo)

Challenges of data sharing, consistency and compatibility are neither new nor unique to borne digital data, but have become far more visible with the tools and expectations of the digital era. Fundamentally, this is a positive development, but it does require innovation and attention to data management at all stages of research.

For example, incorporating Linked Open Data standards and controlled vocabularies at the collection stage, is likely to result in an improvement of data FAIRness by default, making it less of a daunting task towards the end of a project.

As a pragmatic approach, this paper supports the use of software- and platform-agnostic data strategies that allow field archaeologists and specialists to leverage their existing knowledge while preserving the integrity of the data.

While focusing on Mediterranean projects, the paper will compare experiences of digital recording in small research-focused fieldwork projects with those of larger institutions, exemplified with the Norwegian University Museums' field units. The goal of creating consistently valid, preservable, and FAIR data is shared across the two research

situations, but the opportunities and constraints differ considerably. Thus, different approaches to software development and data management strategies might be necessary.

Special attention will be paid to the integration of GIS and 3d data in field recording solutions. The advent of cheap, but flexible RTK GNSS receivers, faster 3d modelling workflows, and customisable Open Source web-GIS libraries has created radically new opportunities. Spatial analysis and data capture need no longer be separate actions, but can take place on site by those closest to the data in the dirt. This has potential to break down barriers between researchers and foster a more reflexive field praxis.

6 HOCUS POCUS AND THE LOCUS IS DONE. USING LARGE LANGUAGE MODELS IN TRANSCRIBING AND PARSING FIELD NOTES

Paukkonen, Nikolai (University of Helsinki)

For the last two years, various so-called artificial intelligence (AI) applications and especially large language models (LLM) have been featured prominently in the media. Multiple uses in various fields have been already found, with several attempts made to utilize them in archaeology as well. One possibility would be to use advanced speech-to-text capabilities in addition to LLM's chat interface to format freely spoken documentation (describing e.g. stratigraphical units, finds or samples) into a shape that can be used for instance to automatically update stratigraphical databases.

In this paper I present a prototype of an open-source Android application that communicates with OpenAI API to convert audio recorded through its microphone into pre-formatted JSON data. In addition to presenting the application itself, some test results from the field are also examined, with focus on the ease of use and reliability. The approach could make possible fieldwork without writing - whether on notebooks, laptops or tablets - and thus ensure consistent quality of documentation, even in extreme conditions, such as subzero temperatures or rain.

7 DIGITAL RECORDING FOR FIRST RESPONSE MISSIONS TO CULTURAL HERITAGE SITES IN DISASTER ZONES

Fritsch, Bernhard (DAI) - Iacono, Elvira (DAI) - Marzban, Pouria (DAI) - Ducke, Benjamin (DAI)

The German Archaeological Institute (Deutsches Archäologisches Institut, DAI), the Federal Agency for Technical Relief (Technisches Hilfswerk, THW), and the Leibniz Research Institute for Archaeology (LEIZA) have jointly developed KulturGutRetter (KGR), as a first response unit for recording and securing cultural heritage material affected by destructive events. The intention behind it, for the existing expertise in Germany, is to focus on a team of experts that can act quickly in the event of a crisis in order to assist in stabilizing, preserving and, where needed, salvaging objects and buildings.

In order to facilitate future rescue missions and to guarantee a consistent and efficient collection of data, KGR is working on systems of data collection, evaluation and processing that can be used before, during and after a catastrophic event. While data acquisition and management in a KGR mission necessitate lots of special requirements, setting up an appropriate data model utilizing open source software is fundamental to satisfy the needs of different areas of expertise involved. The overall workflow and tools used can also easily be adopted for excavation documentation and archaeological research purposes.

In this presentation, the complete process of the KGR mechanism from gathering data in challenging environments by using mobile devices, up to the final transfer of completed data packages, are shown as well as the possible adoptions of the workflow for other areas of archaeological work. The goal of the digital backbone of KGR is to use international standards in terms of terminology and, at the same time, to keep the processes as simple as possible, so that the work can quickly be executed also by volunteers and on short notice, since time is a crucial factor in documenting cultural heritage in crisis situations.

1078 WOMEN AT ARCHEOLOGICAL CONFERENCES FROM THE 19TH CENTURY TO THE LATE 1990S: PRESENCE, REPRESENTATION AND EXPERIENCES

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Gustavsson, Anna (Gothenburg University) - Coltofean, Laura (Research Cluster 5: History of Archaeology, German Archaeological Institute, Germany) - Bucolo, Raffaella (University of Verona, Italy) - Gutschmiedl-Schumann, Doris (University of the Bundeswehr Munich, Historical Institute, Germany)

Session format: Regular session

This session explores female presence and experiences at archaeological and related scientific meetings in Europe and beyond from the long nineteenth century to the late 1990s. It aims to survey all aspects of women's representation and participation at congresses, conferences, symposia and more, from amateurs and professionals to independent

and accompanying delegates (e.g., as wives and daughters of male delegates). The focus is especially on archaeological meetings (e.g., CIAAP, UISPP, EAA); however, congresses of archaeosciences (e.g., ICAZ) and other archaeological sub-disciplines are equally relevant, as well as neighboring fields such as geology, anthropology, history and paleontology depending on the extent of their interdisciplinary nature and connection to archaeological research activities. We welcome papers that examine any of the following topics and more:

- methodological approaches to identifying and studying women at congresses via newspapers, archives, oral histories and personal accounts, among other sources;
- case studies about with female participation in general at specific congresses;
- case studies reconstructing individual women's experiences at conferences;
- the networking, knowledge exchange and career perspectives that such events opened for women;
- the role of intersectionality in female access to, participation in, and experiences at congresses.

Finally, the session also aims to map the current state of research on women's engagement in congresses in the history of archaeology and establish a network of researchers interested in the topic.

ABSTRACTS

1 ROSALIE OLIVECRONA AND THE 1869 INTERNATIONAL CONGRESS OF PREHISTORIC ANTHROPOLOGY AND ARCHAEOLOGY IN COPENHAGEN

Gustavsson, Anna (Dep of historical studies, Gothenburg University)

In 1870, the Swedish author and women's right activist Rosalie Olivecrona (1823-1898) published a travel report and review covering the 1869 CIAAP congress in Copenhagen. The report was printed in *Tidskrift för hemmet*, a women's magazine founded by Olivecrona and her friend Sophie Adlersparre (1823-1895). The magazine was dedicated to "the women of the Nordic countries". The text is valuable both as contemporary congress report, and because it is a published account authored by a female participant.

This paper aims at discussing Olivecrona's impressions and experiences at the congress 1869, by looking into which themes and elements she chose to write about, and how she wrote about them. Apart from educating her readers and update them with scientific news, Olivecrona commented on the participation of women at the congresses, and in science in general. Furthermore, this contribution will discuss how the report -the genre and Olivecrona's specific report- can serve as a point of departure for a deeper analysis of the issues and debates in the society of the era, which was mirrored and confronted in Olivecrona's text.

2 SCIENCE BEHIND LEISURE: WOMEN AT THE 1876 INTERNATIONAL CONGRESS OF PREHISTORIC ANTHROPOLOGY AND ARCHAEOLOGY

Coltofean, Laura (Archaeology and Gender in Europe (AGE) - EAA Community; Research Cluster 5: History of Archaeology, German Archaeological Institute)

This paper discusses the participation of women at the 8th Congrès international d'anthropologie et d'archéologie préhistoriques (CIAAP; International Congress of Prehistoric Anthropology and Archaeology) organized at the Hungarian National Museum in Budapest, Hungary, in 1876. Using the publications resulting from the congress, newspapers articles and archival material, the paper first explores the methodological approaches which can be applied to identifying the women who joined the 1876 CIAAP – and other similar scientific meetings in general – and subsequently to reconstructing their collective and personal experiences at the event. The paper then offers an inter-sectional, quantitative, and comparative analysis of female and male, both domestic and international, presence at the congress, which aims to assess the existence of underlying patterns in their attendance. It also examines the ways in which women are portrayed in the scientific programme, in preparing the archaeological exhibition of the congress, in leisure activities such as excursions, parties, and meals organized as part of the congress, as well as in anecdotal accounts. Finally, the paper offers insights into individual women's experiences at the 1876 CIAAP, highlighting the networking and knowledge exchange they engaged in, as well as the career opportunities the event opened for them.

3 JOHANNA MESTORF AT THE INTERNATIONAL CONGRESSES OF PREHISTORIC ANTHROPOLOGY AND ARCHAEOLOGY 1869-1876

Koch, Julia (Universität der Bundeswehr München)

Johanna Mestorf, curator at the Museum Vaterländischer Alterthümer (Museum of Patrimonial Antiquities) at the University of Kiel (Germany) from 1873 and director of this museum from 1891 to 1909, was one of the few women to obtain a paid position in European archaeology in the 19th century. The participations to the International Congresses of Prehistoric Anthropology and Archaeology (CIAAP) in Copenhagen in 1869, Bologna in 1871, Brussels in 1872,

Stockholm in 1874 and Budapest in 1876 are named as important stations in her professional career. She published detailed reports on her travels from 1871 to 1876. Through her participation, she gained national and international reputation among the (male) scientific community. But what was so special about it, apart from the fact that she was at the first congresses the only woman to take part as a professional scientist?

The first part of the paper presents the obstacles that a single, middle-class woman in 19th century Europe had to overcome if she wanted to travel to a congress. How did Johanna Mestorf prepare for her participation? How did she finance her travels? What social restrictions did she experience?

The second part examines Johanna Mestorf's participation in the congresses. How did she manage to be recognised as an archaeologist even though she was not allowed to give papers herself? What role did she play at these congresses? And how did she manage to personally build up an international network that included prominent archaeologists of her time?

The paper will discuss in more detail the importance of travelling to conferences for Johanna Mestorf's career and the effect of her presence on the acceptance of women in archaeology in the 19th century.

4 THE ARCHAEOLOGIST MARGARETE GÜTSCHOW AND WOMEN'S PARTICIPATION AT THE 3RD INTERNATIONAL ARCHAEOLOGICAL CONFERENCE OF ROME IN 1912

Bucolo, Raffaella (Verona University)

This paper aims to explore the participation of women in archaeological conferences in the early 20th century, starting from a specific case of study, an individual experience of Margarete Gütschow (1871-1951). Gütschow should be included among the first women who played a role in the development of the archaeological discipline: her life story, found partly within her correspondence, has allowed us to understand her personality and work as part of the German Archaeological Institute in Rome.

In 1912, she attended the 3rd International Archaeological Conference, which was organized in Rome by the most important scholars of that time. By examining the conference program and archival material, I will investigate female participation at the Roman Conference of that year in terms of numbers and roles. At the same time, one of my goals is to understand the possible networking that the specific event opened for Margarete Gütschow. Her correspondence and life story are enriched with the names of other female archaeologists, friends, and colleagues with similar paths.

As known from an archival document, during the event, exclusively women participants could be hosted at the "Lyceum" of via del Tritone, the seat of a female cultural association: it would be interesting to define the role of the "Lyceum" as a place of exchange among women or of isolation from men.

5 WOMEN OF ARCHAEOLOGY AND THE LIMES CONGRESS

Ivleva, Tatiana (Newcastle University) - Jones, Rebecca (Heriot-Watt University)

The paper discusses the participation, role, and influence of female archaeologists in the International Congress of Roman Frontier Studies ('LIMES Congress'). This Congress is a worldwide academic forum for researchers working on all aspects of Roman frontier archaeology. The Congress has a long history, with 25 congresses in the 75 years since the first congress in 1949. The number of male attendees has always outnumbered the number of women, perhaps no surprise given the military focus of the conferences and history of our discipline.

In this paper, we present an analysis of the presenters' gender over the past 70 years and discuss the involvement of female researchers and professional female archaeologists on specific geographical frontier zones and topics. Our research of the past Congress' books of abstracts and proceedings has shown a notable discrepancy in the gender balance in the study of certain Roman provinces and the topics presented. Research on military sites, the Roman army, and late Antiquity is heavily dominated by men, with no area seeing more women presenting than men. However, the balance is reasonable when it comes to certain aspects of material culture, frontier society, and civilian settlements. Moreover, while female scholars working on Eastern European, Balkan, Rhine, and Danube frontiers are well-represented and frequently attend the Congresses, there is an overwhelming and continuous dominance of male academics when it comes to research on British, Near Eastern, and North African frontiers. We evaluate the reasons for such discrepancies and discuss whether the growing number of participating women archaeologists has contributed to shifting the balance. Alongside the official Congress publications, we have used oral histories and personal accounts of still living women participants.

6 THE ROLE OF WOMEN ARCHAEOLOGISTS IN ORGANIZING ARCHAEOLOGICAL CONGRESSES IN UKRAINE

Shabelnikova, Irina (Oles Honchar Dnipro national university)

Archaeological congresses in Ukraine were held at the initiative of the Moscow Archaeological Association from 1869 to 1911. During this period, 15 congresses were organized, 6 of which in Ukraine: the 3rd and 11th in Kyiv (1874, 1899), the 6th in Odesa (1884), the 12th in Kharkiv (1902), the 13th in Katerynoslav (1905), and the 14th in Chernihiv (1908). These meetings contributed to research on antiquities in the places where the next congress was to be held, to the emergence of archaeological associations and museums, and overall to the formation of archaeology as a discipline in Ukraine. Reports and summaries on archaeology, history, historical geography, art history, ethnography, numismatics, etc. were presented at the congresses and published in the volume of summaries "Trudy". In addition, the excursions and exhibitions included in the program introduced numerous archaeological monuments into scientific circulation.

Dozens of publications have been devoted to the congresses so far, focusing especially on their scientific content. However, these meetings have not been examined yet from the perspective of women's history. This paper, therefore, discusses the role of women archaeologists in organizing archaeological congresses in Ukraine, which was one of the easiest ways for them to join the archaeological community of the conservative intellectual society of the nineteenth and early twentieth centuries. It particularly focuses on women such as P. Uvarova, K. Melnyk-Antonovych, K. Skarzhynska, A. Kartsova-Miklashevska, A. Skrylenko, N. Polonska-Vasylenko, V. Kozlovska, I. Fabrycius, and M. Viazmitina, among others. Their participation in these events is an example of their search for ways to influence the social and cultural realities of their times, as well as an attempt to assert themselves as specialists in the field of archaeology.

7 WOMEN'S PARTICIPATION IN ARCHAEOLOGICAL CONFERENCES IN THE EARLY FEDERAL REPUBLIC OF GERMANY

Gutmiedl-Schuemann, Doris (University of the Bundeswehr Munich, Historical Institute)

The aim of this paper is to explore the participation of women in archaeological conferences in the early Federal Republic of Germany (especially in the 1950s). Several conferences, mainly focusing on prehistoric and protohistoric archaeology, were held regularly in different places, such as the Annual Meeting of the "Nordwestdeutscher Verband für Altertumsforschung" or the "West- und Süddeutscher Verband für Altertumsforschung". However, since each conference was organized independently by local groups, the representation of women and female archaeologists varied from one event to another from year to year.

For this paper, I examined archival material, especially lists of participants and conference programs. This material reveals that the participants were sometimes registered and addressed in a gender-neutral way, while in other occasions and conferences gender was highlighted by the modality used to register the participants. This can also be observed in the conference programs.

After presenting the archival material, I will explore the impact of the different modes of representation of female participants on the women archaeologists and their careers.

This paper is part of the ongoing research project "Akteurinnen archäologischer Forschung zwischen Geistes- und Naturwissenschaften: Im Feld, im Labor, am Schreibtisch" (AktArcha) on female archaeologists at the Historical Institute of the University of the Bundeswehr Munich.

8 "NO NEED TO HIDE IN THE CORNER": THE LEGACY OF MARIA GIMBUTAS (1921-1994) AT INTERNATIONAL CONFERENCES AND SCIENTIFIC EVENTS

Civilyte, Agne (Lithuanian institute of History)

This paper is dedicated to the works of archaeologist Maria Gimbutas (1921-1994), the creator of the famous Kurgan and Mother Goddess hypotheses. After escaping from the Soviet occupation and the looming repressions in her home country, Lithuania, Gimbutas survived difficult years in refugee camps in Germany and experienced many challenges as an immigrant in the United States. Despite these hardships, she remained an active researcher and defended her doctoral thesis at the University of Tübingen, Germany in 1946.

Gimbutas continued working after she moved from Germany to Boston in 1949. Her participation in different congresses, especially where she first presented her ideas about the migration patterns of the Kurgan people, brought her into the spotlight. This paper will give an overview of how Maria Gimbutas worked as a co-organizer of congresses, how the topics of those scientific events and of her own papers were selected, and how her ideas were received in archaeology in the second half of the twentieth century based on archival material, personal memories, and her diary.

Furthermore, the paper will discuss how Gimbutas managed to maneuver complex political constraints and disseminated her ideas not only in the free world, but also behind the Iron Curtain during the Cold War.

9 HELGA HERDEJÜRGEN, A MODERN ARCHAEOLOGIST

Cipriani, Mariella ("Tor Vergata", University of Rome)

This paper intends to draw attention to a prominent female figure in twentieth-century classical archaeology: Helga Herdejürgen (Bremen, 1938-Bonn, 2001). As a student of classical archaeologist and art historian Ernst Langlotz (1895-1978), she authored more than 40 publications, including monographs, corpus of sarcophagi, exhibition catalogues, articles and reviews. She had important contributions to the field of Tarentine coroplastic art, the study of the sarcophagi from Campania, Ravenna and Ostia and the "luxury mythological reliefs" from Rome. Moreover, she bravely challenged widely accepted ideas in classical archaeology and suggested new interpretations, as in the case of the "mythological Spada reliefs" which she dated to the Augustan age instead of the Hadrian age. She faced with rigorous scientific method and great determination all the challenges of her life, including illness in her final years. She worked as an independent researcher in Basel and Bonn and then as a corresponding member of the German Archaeological Institute in Rome, where she lived for a great part of her life. Despite her important research, she never received the proper academic recognition she deserved. Unfortunately, she died just a few months after receiving the invitation to participate as main speaker in the 41st Conference on Magna Grecia in Taranto, one of her main research topics. Despite her important work, Helga did not participate in any other conference except the "International Vase Symposium" in Amsterdam in 1984 and this paper examines the reasons behind this intriguing aspect of her scientific activity.

1081 EXPLORING WETLAND SETTLEMENTS: ARCHAEOLOGICAL RESEARCH METHODOLOGIES AND EMPIRICAL INSIGHTS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Di Giamberardino, Giulia (Sapienza Università di Roma) - Hafner, Albert (Universität Bern) - Mangani, Claudia (Museo Civico Archeologico "Giovanni Rambotti") - Hinz, Martin (Universität Bern)

Session format: Regular session

This session explores the invaluable insights offered by wetland settlements; an exceptional but challenging data source compared to dryland conditions. The recovered information from these sites plays a pivotal role in reconstructing the life of past communities.

Our session focuses on archaeological research methods applied to investigate wetland contexts. We invite papers focusing on methodologies to reconstruct various facets of everyday life within these settlements, encompassing human-environment interactions, interpersonal relationships, settlement origins and evolution, distinctive features.

The session encourages both traditional and innovative methodologies, with an empirical emphasis on direct contextual knowledge acquisition. We particularly encourage papers highlighting scientific innovations and advancements in research methods, such as but not limited to the following:

- Dendrochronology and dendrotypology (which, due the traditional approach and scientific innovation, are useful for defining the shape and size of structures and settlements, as well as for understanding the dynamics of forest management);
- Material distribution in space (which, with the use of GIS and statistics methods, helps us to understand the different areas of use within the structure and settlement or the connections between different communities);
- Micromorphology (which can enhance our knowledge in understanding phenomena that may influence the entire settlement life, such as lake level fluctuations, to more specific situations, like hearth components extracted from thin sections).

Embracing a pragmatic approach, alternative methodologies and approaches beyond those specified are most welcome. While the geographical focus is on Central and Southern Europe, and especially the Alpine area linked to the serial, transborder UNESCO World Heritage "Prehistoric pile dwellings around the Alps" and the Mediterranean regions, case studies from other areas are encouraged. The session targets the Neolithic and Bronze Age facilitating meaningful cross-contributory comparisons.

1 SOME METHODOLOGICAL THOUGHTS ON PILEFIELD ANALYSES AND DENDROCHRONOLOGY

Bleicher, Niels (Underwaterarchaeology / DendroLab City Of Zürich) - Nelle, Oliver (Landesamt für Denkmalpflege Baden-Württemberg) - Bolliger, Matthias (Archäologischer Dienst, Kanton Bern) - Blum, Jonas (University Zurich)

Circumalpine prehistoric wetland and lakeside sites often yield very large pile fields containing several tens of thousands of piles. Dendrochronological crossdating of these is the basis for many different analyses – be it of architecture, social space or typochronologies. Frequently, these pile fields represent remains of several if not many construction phases one on top of another. Identifying and interpreting the individual phases within these stacked ground plans is a difficult task, the methodology of which has attracted too little attention. This also holds true for underlying assumptions that are often made implicitly or even unconsciously. Standard spatial statistics are frequently of little help as they are designed to describe only one point process at once. Furthermore, in the case of short tree-ring series, the context can be important for the dendrochronological crossdating, resulting in non-independent dendro-dates. But what is context in a multi-process point cloud? How can we define and identify context? How can we form and test hypotheses?

In this paper, we reflect on these questions and outline possible approaches to their solution.

2 HOW ASTRONOMERS REVOLUTIONIZED ARCHAEOLOGY: TREE RINGS, SOLAR OUTBURSTS, AND ARCHAEOLOGICAL INTERPRETATION

Hafner, Albert (University of Bern; Oeschger Centre for Climate Change Research)

In 1929, the American astronomer Andrew Ellicott Douglass published a seminal paper in dendrochronology titled “The Secret of the Southwest Solved by Talkative Tree Rings. This ground-breaking work outlined Douglass’s findings on the correlation between tree rings and climate, laying the foundation for dendrochronological dating methods. In 2012, Japanese astronomers led by Fusa Miyake presented another most significant paper titled “A signature of cosmic-ray increase in ad 774-775 from tree rings in Japan. For nearly a century, dendrochronology has played a crucial role in archaeological dating. In the 1940s, the first studies were conducted on wood samples from pile-dwelling settlements. Since the 1980s, a continuous tree-ring calendar has been available for areas north of the Alps. This revolutionized established chronological models. The discovery and application of “Miyake events” in archaeology brought a paradigm shift in absolute dating, showcasing the intricate interplay between dendrochronology and radiocarbon dating. This presentation will delve into the evolution of dendrochronology from its inception in the study of pile dwellings to the present day. It will explore the transformative impact of high-precision dating on archaeological interpretation.

3 HIGH RESOLUTION EARLY SUMMER PRECIPITATION RECONSTRUCTION FOR THE 55TH-52ND CENTURIES BC IN THE KASTORIA BASIN, NORTH-WESTERN GREECE

Maczkowski, Andrej (University of Bern) - Francuz, John (Institute of Archaeological Sciences, University of Bern, Switzerland) - Bolliger, Matthias (Institute of Archaeological Sciences, University of Bern, Switzerland; Laboratory for Dendrochronology, Archaeological Service Canton of Bern, Switzerland) - Giagkoulis, Tryfon (School of History and Archaeology, Aristotle University of Thessaloniki, Greece) - Kotsakis, Kostas (School of History and Archaeology, Aristotle University of Thessaloniki, Greece) - Hafner, Albert (Institute of Archaeological Sciences, University of Bern, Switzerland)

The Neolithic site of Dispilio on the shores of Lake Kastoria, Greece, is arguably the best-known lakeside settlement in the southern Balkans. The long research history and excellent preservation at Dispilio offer a unique insight in Neolithic way of life. In the 2019 fieldwork campaign several hundred wooden piles - remains of prehistoric buildings - were sampled for dendrochronological analysis. The dendrochronological analyses yielded an oak and a juniper tree-ring chronologies spanning the 55th-52nd centuries BC. The combination of dendrochronology and annual radiocarbon have recently provided calendar-year absolute dating for Dispilio’s tree-ring chronologies, placing the end of the juniper chronology at precisely 5140 BC. As tree-ring growth in the region is in great part limited by summer moisture availability, tree-rings can be used a proxy for climate reconstructions. A modern reference collection of juniper tree-rings sampled around Lake Prespa have been used as a calibration dataset with modern instrumental climate data. This modern reference tree-ring chronology revealed that juniper tree-ring growth in this part of the Balkans is most sensitive to May-June precipitation. The coefficients describing the relationship between modern tree-ring and instrumental climate data were applied to the prehistoric Dispilio juniper chronology thus providing the first annually resolved early summer precipitation spanning from the later 55th till mid-52nd century BC in the region.

4 WOODWORKING AND WOOD MANAGEMENT IN A PREHISTORIC PILE DWELLING: THE CASE STUDY AT LUCONE D

Maltese, Giuseppe (Department of Cultures and Civilizations, University of Verona – Italy) - Martinelli, Nicoletta (Laboratorio Dendrodata – Italy) - Saletta, Emanuele (Lares - Restauri S.R.L. – Italy) - Baioni, Marco (Museo Archeologico della Valle Sabbia – Italy)

The Lucone D settlement, one of the sites identified in the inframorainic basin of Lucone di Polpenazze del Garda (Italy), has been excavated, under ministerial concession, by Museo Archeologico della Valle Sabbia from 2007 to today. The site, dated by dendrochronology between 2034 and 1967 ± 10 cal BC, is a good example of an Early Bronze Age pile-dwelling settlement. The research produced concrete data regarding the elevation of the pile-dwelling structures and the use of wood resources. In Sector 1 (the excavation is divided into two sectors), a programme of extensive dating of all vertical poles using dendrochronology made it possible to recognize the various felling phases and therefore the contemporary elements. However, applying this method at Lucone D has revealed some challenges, i.e., managing a vast amount of planimetric and chronological data and interpreting a complex operational chain of timber management. This includes storing logs felled in later years and possibly reusing structural elements already in place.

A significant aspect of the site is that the settlement was involved in a fire, which led to the end of its first phase, the collapse of the structures, and the preservation of many wooden and clay structural elements belonging to the houses. This allowed a detailed analysis of the architectural aspects, highlighting various types of joints and ropes. The framing elements show remarkable skill in woodworking, with different wood taxa, allowing a typological classification. Integrating the techno-morphological and xylological analyses gives us a clear vision of the use of wood species in building the village. This vision is made tangible by the first virtual reconstruction of one of the identified structures (2031 BC).

5 THE RECONSTRUCTION OF DWELLINGS IN WET AREAS THROUGH STRUCTURAL CALCULATIONS AND DIFFERENT METHODOLOGIES: AN INTERDISCIPLINARY APPROACH

Di Giamberardino, Giulia (Sapienza Università di Roma) - Mangani, Claudia (Museo Civico Archeologico “Giovanni Rambotti”) - Vanzetti, Alessandro (Sapienza Università di Roma) - Baioni, Marco (Museo Archeologico della Valle Sabbia)

The structural reconstruction of dwellings, especially in wet environments, has until today mainly focused on the location and foundation of buildings (the issue can be oversimplified through the opposition between raised and ground floors) and on their planimetric reconstruction.

Different pieces of information and methodologies can be combined together, like dendrochronology, planimetric reconstruction, distribution of archaeological materials, and paleoenvironmental data for the reconstruction of lake-shore fluctuations over time. These pieces of information, extremely useful on their own, could potentially provide more insight through the in-depth study of other methods still waiting widespread application, such as structural calculations derived from structural engineering applied to archaeological excavation data. Even if these methods are suited for modern goals, they can provide a baseline for the study of the past.

It is thus possible to expand interdisciplinarity through a critical quantitative approach, in order to obtain a more secure reconstruction of the pile-dwelling, beyond typological issues. Data can be properly connected together, through a more realistic reconstruction of the pile-dwelling, also for answering questions such as the technological skill of the group/single builder, the actual use of spaces inside the house, the social organization of community and settlement systems, the evidence of possible contacts and transmission of knowledge within wider areas (such as the Alpine arc), the wider cultural interconnections.

The aim of this intervention is to test the utility of the structural calculations as a mediator of the different research strains; it will be discussed through different case studies, among which Lucone di Polpenazze, aiming also to understand whether data recovered from contemporary and past excavations of wet contexts are sufficient or require new integrations.

6 THE PROTOHISTORIC LAKESHORE SETTLEMENT OF PADULI (COLLI SUL VELINO, RI). MULTIDISCIPLINARY APPROACH TO THE KNOWLEDGE OF A WETLAND SITE

Virili, Carlo (Department of Science of Antiquities, Sapienza University in Rome) - Zanini, Alessandro (Independent researcher) - Jaia, Alessandro M. (Department of Science of Antiquities, Sapienza University in Rome)

Since 2015 the Department of Antiquities -Sapienza University of Rome has been excavating the lakeshore settlement of Paduli near the modern Piediluco lake. The aim of the project is the analysis of the diachronic development of human adaptation to the lake site. The environmental context has inevitably conditioned the settlement structure and the socio-economic articulations of this territorial system made up of a polycentric network of lacustrine villages with a long continuity of life. The beginning of the occupation of the site seems to begin in the initial phases of the Middle

Bronze Age, a moment which marks the genesis of a long historical cycle of occupation of the Piediluco basin which lasted without discontinuities until the oldest phase of the Early Iron Age. In the Recent Bronze Age the development of the settlement proceeds with the presence of a domestic structure resting on a reclamation platform made up of wooden beams. The Final Bronze Age is the period of maximum development of the area. Paduli site occupies almost twenty hectares of surface and could be the most extensive site of the local settlement system. In the Early Iron Age, shows a use to open area over a base platform consisting of a grid of wooden branches. The data collected by the multidisciplinary study (radiometric, archaeometric, paleobotanical, archeozoologic, sedimentological and paleoclimatic) confirms the importance of the site: at the end of the II millennium BC, phenomena of social complexity seem to emerge behind which there are rising local elites capable of inserting themselves into the network of international traffic could be hidden. Few generations after its maximum, the site undergoes a contraction up to the almost total disappearance of the archaeological evidence in Recent Iron Age, as happens, in synchrony, in almost all the sites of the Piediluco lake.

7 LOST AND FOUND: THE PREHISTORIC PILE-DWELLING IN BUDINŠČINA, CROATIA

Jerbic, Katarina (University of Bern, Institute of Archaeological Sciences) - Solter, Ana (Archaeological Museum in Zagreb) - Hafner, Albert (University of Bern, Institute of Archaeological Sciences)

One of the earliest known records on pile-dwellings on Croatian territory date back to 1885, when Š. Ljubić, director of the Archaeological department of the National Museum in Zagreb, found sharpened wooden piles in a marshy ground near the village of Budinščina in today's north-western Croatia. He reports that the piles were placed in regular formations in the ground and he identified them as remains of a prehistoric pile-dwelling, comparing them to the Terramara pile-dwelling in Italy. He presented his findings to Luigi Pigorini, the archaeologist working on Terramara at the time, who's work there is considered as one of the crucial findings of the 19th century "Pile-dwelling fever" around the Alpine lakes. After a season of excavations and personal consultations with Pigorini in the form of letters, and a presentation at a prehistoric pile-dwelling conference in Celje (Slovenia) Ljubić published his work on Budinščina in two short reports in 1885 and 1887. Although he presented the site as highly significant, the interest in the site has faded, and Budinščina hasn't been excavated since. That was until 2024 when, as part of the SNSF-funded post-doctoral project "Between the Alps and the Balkans: Prehistoric pile-dwellings around Croatia", the site was included in the program as a revision investigation in the form of sediment core samples, test excavation trenches and drone footage. In this paper we will present Ljubić's findings by using data and archaeological finds from the Archaeological Museum in Zagreb's archive and depots. This research will then be used as comparative data for the new findings expected to emerge from the planned revision in 2024. A crucial part of the paper includes the original letters between Ljubić and Pigorini, adding historical value and significance to the re-emerging interest in the topic of prehistoric pile-dwellings across Croatia.

8 THE WETTER PART OF THE NEOLITHIC DAWN OF EUROPE: RESULTS FROM LIN 3, LAKE OHRID, ALBANIA

Hinz, Martin (University of Bern) - Anastasi, Adrian (Institute of Archaeology - Academy of Albanological Studies, Tirana) - Brunner, Mirco (University of Bern) - Anastasi, Kristi (Université Lumière Lyon 2) - Hafner, Albert (University of Bern)

Initiated in 2019, the EXPLO project has embarked on a comprehensive examination of lakeshore settlements in the southern Balkans, with a focus on the vicinity of Lake Ohrid. The project expanded its research to include the Albanian Lin 3 site near Pogradec in 2020. Our findings at the Lin 3 site reveal at least two distinct phases of settlement, offering a glimpse into the early Neolithic lifestyle in Europe from a wetland perspective. The initial phase, identified through land-based wetland excavations, dates back to 6000-5800 BCE, positioning Lin 3 as the continent's earliest known Neolithic pile-dwelling settlement. At present there is evidence of an even earlier occupation of the site, which aligns the origins of the site with the beginning of Neolithisation in the Balkans, but in general the absolute chronological information available to us confirms the multiple phases typologically identified so far.

A subsequent phase, explored primarily through underwater archaeology, features a significant fortification represented by a three-tiered palisade complex from the late 6th millennium. Anticipated updates on its dating will be disclosed during our presentation. Echoing the magnitude of defensive structures found in Thessaly's renowned Neolithic sites, such as Sesklo and Dimini, this discovery promises to reshape our understanding of Neolithic defensive strategies and community organization. This presentation aims to unveil the latest findings from Lin 3, highlighting its significance in the broader context of Neolithic.

9 SIEVING FOR BONES: FISH EXPLOITATION IN THE PO PLAIN DURING THE BRONZE AGE

Prillo, Vito Giuseppe (University of Padua, Department of Cultural Heritage, Italy.) - Baioni, Marco (Museo Archeologico della Valle Sabbia, Gavardo, Italy.) - Cupitò, Michele (University of Padua, Department of Cultural Heritage, Italy.) - D'Aquino, Silvia (University of Padua, Department of Cultural Heritage, Italy.) - Minniti, Claudia (Department of Sciences of Antiquities, Sapienza University of Rome, Italy.) - Nicosia, Cristiano (Department of Geosciences, University of Padua, Italy.) - Sarnico, Valeria (Department of Humanistic Studies, University of Ferrara, Italy.) - Vidale, Massimo (University of Padua, Department of Cultural Heritage, Italy.)

This paper will present and discuss the zooarchaeological evidence of fishing activities practiced during the Bronze Age in the Po Valley (northern Italy), where numerous pile-dwelling and Terramara sites were located. In particular, freshwater fishing had to play a central role for the subsistence of settlements located in a geographical area strongly connected to water sources and wetlands.

Due to the fragile state of preservation of fish remains, our knowledge of these practices has remained limited and has focused primarily on documentation of tools that may be associated with them, such as fishhooks and net floats.

Analyses of fish remains found in the sites of Lucone di Polpenazze (EBA), Oppeano 4D (MBA), La Muraiola - Povigliano Veronese (MBA), Pilastrì di Bondeno (MBA-RBA), Fondo Paviani (RBA) and Villamarzana (FBA-EIA) were carried out as part of a doctoral project developed at the University of Padua and here presented. They revealed that the fishing was mainly geared towards pike and cyprinids.

Biometric and seasonal data further define the importance of fish in the diet throughout the Bronze Age and provide new information on the fishing strategies practiced by ancient communities.

10 A UNIFIED RAW AND FIRED CLAY ANALYSIS METHOD: MATERIAL SHEET AND APPLICATION TO "LUCONE D" PILE DWELLING SITE STRUCTURES

Bonusi, Stefano (Museo Archeologico della Valle Sabbia; Università degli Studi di Padova) - Baioni, Marco (Museo Archeologico della Valle Sabbia) - Tasca, Giovanni (Università degli Studi di Padova)

The study of raw and fired clays, known in Italy as "concotti", is often a niche topic within the archaeological community, leading to a lack of uniformity in study methods and data processing. In this context, we aim to fill this gap by proposing a unified study method based on the compilation of a materials sheet specifically designed for this class of materials.

This sheet is intended to be completed in two distinct phases: one during excavation and one during the study. The fields include excavation coordinates, the preservation state of the fragment or structure, possible recognizable signs on the element's surface, color (based on Munsell charts), paste class, weight, and firing/burning; it also includes dedicated spaces for the insertion of a schematic drawing of the fragment, as well as its identifying photo and reference code within a digital archive. These precautions are essential for studying these materials over time, as clays, even when preserved, are often subject to wear and tear.

The practical application of this sheet followed its creation during the study of materials from the UNESCO pile-dwelling site of "Lucone D" of Lucone di Polpenazze (IT), specifically focusing on fragments of a structure identified, among other hypotheses, as a possible grain storage silo built using a modular elements construction technique.

This technique was previously known for the Iron Age, extending back at most to the Late Bronze Age, and now, through the observations made in this study, it can be dated back to the Early Bronze Age.

1082 THE ARCHAEOLOGY OF EU-POTARCH: THE PRODUCTION OF POTASH, TAR, RESIN AND CHARCOAL IN THE ARCHAEOLOGICAL RECORD

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Nelle, Oliver (State Office for Cultural Heritage Baden-Württemberg; University of Regensburg) - Deforce, Koen (Ghent University; Royal Belgian Institute of Natural Sciences) - Burri, Sylvain (French National Centre for Scientific Research, TRACES UMR 5608 CNRS - Université Toulouse Jean Jaurès)

Session format: Regular session

Potash, tar, resin, and charcoal (PoTaRCh) are four materials closely linked in their materiality, of extraordinary importance for societal resource use and the most important products of non-timber forest use in Europe. Related to production and use are questions of competitive material sourcing, sustainability, overexploitation and socio-economic consequences which bring together scholars from different disciplines, as well as museum actors and people still producing in a traditional way. A newly established EU-COST-action (www.cost.eu/actions/CA22155) aims to improve, by networking of scientists and practitioners researching and working on PoTaRCh in Europe and beyond, the understanding of (pre-)historical developments and patterns and the heritage legacy. In this session, we focus on

the archaeological record of the production sites, including archived ecofacts. Numerous studies in Europe investigate charcoal production sites, but also tar production. Potash and resin production is rarely tracked archaeologically, thus contributions on these non-timber woodland products are highly welcomed, as are all contributions dealing with excavations, lidar-detection, using the sites as archives for environmental history, etc. Charcoal production sites are used as archives for woodland reconstructions by analysing their wood charcoal remains. Distribution and density give valuable insight into former land use intensities, also in marginal regions. Archaeological excavations are important to understand usage period and multiphasing. The archaeological sites yield remains of the processing, which can be analysed for their chemical composition.

ABSTRACTS

1 THE PRODUCTION OF POTASH, TAR, RESIN AND CHARCOAL IN THE ARCHAEOLOGICAL RECORD

Nelle, Oliver (Landesamt für Denkmalpflege im Regierungspräsidium Stuttgart; Regensburg University) - Deforce, Koen (Ghent University) - Burri, Sylvain (CNRS; University of Toulouse)

Potash, tar, resin, and charcoal (PoTaRCh) are four non-timber materials made from trees. Their production has altered woodlands and landscapes and has left innumerable remains in the case of charcoal production, a considerable number of remains in the case of tar production, but only a few or no traces in the case of potash and resin production or sourcing. In this contribution, we address aspects of the archaeological record of PoTaRCh, show examples of case studies in France, Belgium and Germany, and start to identify gaps which we wish to close in the near future. The archaeological remains of PoTaRCh provide the (pre-)historic material base, the legacy found in the soil, to be able to address questions of competitive material sourcing, sustainability, overexploitation and socio-economic consequences. Production sites, if dated, serve as a temporal-spatial sequence of palaeoarchives of the PoTaRCh-technological evolution in Europe, as well as environmental changes, former vegetation composition and as sources for material for analytical characterisations.

2 INTERDISCIPLINARY RESEARCH ON CHARCOAL KILN SITES IN MONTIERI (TUSCANY-ITALY): ENVIRONMENTAL DYNAMICS AND WOODMANSHIP PRACTICES BETWEEN 18TH-20TH CENTURY

Pescini, Valentina (Catalan Institute of Classical Archaeology (ICAC)) - Gabellieri, Nicola (Università di Trento)

This contribution presents interdisciplinary research on charcoal kiln sites carried out at Poggio di Montieri, Central Italy, a hill heavily exploited in the Middle Ages for the extraction of silver-bearing ore, and then managed until the 19th century with a multiple land use system based on pasture.

Linking together archaeological surveys with anthracological and dendro-anthracological data, as well as with information from historical texts (e.g. by-laws), cartography (e.g. cadastre and pre-cadastre maps of 19th - 18th centuries), and historical ecology observations this research outlines the environmental dynamics that occurred in this area in the last few centuries. In particular, the multiple land use systems and the slope vegetation cover changes will be discussed as well as the definition's criteria applied in cartography for land use descriptions.

Charcoal production sites are valuable archives for woodland reconstructions and environmental management characterization. However, their study needs to be inserted in a cross-disciplinary framework research able to cross-check different historical, archaeological, and environmental sources to identify, in a more realistic way, the woodmanship practices and the complexity of their environmental effects through time. The limits and potentialities of these different sources will be discussed to identify a methodology suitable for the accurate study of the charcoal production sites.

3 A LANDSCAPE AND ENVIRONMENTAL STUDY OF HISTORIC CHARCOAL PRODUCTION IN WEST AND SOUTH YORKSHIRE

Atkinson, Christopher (University of Sheffield)

Charcoal has been an important fuel resource since at least the Iron Age, largely fuelling the iron and steel industries up until the industrial revolution of the 18th century, before being replaced by fossil fuels. The fuel has also been important for the textile industry, heating, cooking, as well as for other applications. Despite its importance in society, the archaeology of charcoal production within the UK has received limited archaeology attention compared to its European neighbours, with investigation relating principally to the identification of individual charcoal burning platforms during chance woodland surveys. These surveys are often associated to the development of woodland management plans, or as part of short-term community or research projects.

This paper summarises my on-going White Rose College of Arts and Humanities funded PhD research at the Department of Archaeology, University of Sheffield which takes a multi-disciplinary approach to the investigation of charcoal production sites within South and West Yorkshire in England.

Utilising traditional woodland survey techniques, remote sensing, historic map regression, historic archives, place-name evidence, geophysical survey, trial excavation, charcoal and pollen analysis, and radiocarbon dating, this research aims to improve the understanding of the charcoal industry in the region.

This integrated research aims to examine the distribution of the charcoal industry across the study area, whilst serving to assess the characteristics of charcoal burning platforms. Excavation also highlights patterns of fuel selection choice and woodland management; narratives of woodland character change; and a chronology of charcoal production at five case-study locations.

This presentation serves as a summary of my research into charcoal production within South and West Yorkshire. The paper will have a particular focus on the ancient woodland of Shipley Glen, Baildon, in West Yorkshire, where investigation has included excavation and environmental sampling for the purpose of pollen and charcoal analysis.

4 EXPLORING ESTONIA'S CHARCOAL BURNING LEGACY

Tomson, Pille (Estonian University of Life Sciences) - Saage, Ragnar (University of Tartu) - Kama, Pikne (Estonian National Heritage Board)

The practice of charcoal burning has previously attracted attention from archaeologists solely in connection with iron smelting in Estonia. The aim of this presentation is to systematically overview existing information about charcoal burning and discuss future research needs.

Within the cultural heritage register, there are 43 charcoal burning sites, of which 14% have been completely destroyed, 38% are difficult to recognize, 43% are partially maintained, and only 2 sites (5%) are well-preserved. None of these sites are under legal protection or have been scientifically studied. The prevalence of charcoal burning heritage is likely much broader, as indicated by archival records at the Estonian National Museum. Questionnaires gathered responses from 98 correspondents of the Museum from various regions of Estonia in 1941-1942. Among them, 71% described charcoal burning at specific sites, 14% mentioned obtaining charcoal from home ovens, 12% were unfamiliar with charcoal burning. Among the 97 responses, charcoal burning in pits was described in 42 cases, while 19 cases mentioned burning in stacks.

In 2023, a charcoal burning area was discovered in the Karula upland in southern Estonia, covering approximately 4 km². This area was identified visually using LIDAR relief maps from the Estonian Land Board. Seven burning pits were measured, ranging from 130-190 cm x 210-265 in diameter and 70-100 cm in depth. These pits were dated to the period of 1284-1410 calAD. Additionally, seven stacks with an average diameter of 6.3 m, along with two smaller stacks (diameter 5.4m), were found. These stacks were dated to the period of 1495-1656 calAD. Archaeological excavations are planned for the summer of 2024.

These findings demonstrate that charcoal burning has been widespread in Estonia. The significance of charcoal burning in the local economy and its importance in the landscape have been underestimated and require further investigation.

5 STUDY OF PRODUCTION TECHNIQUES AND INVESTIGATION OF CHEMICAL DEGRADATION OF MULTI-COMPONENT ARCHAEOLOGICAL ADHESIVES

Bertelli, Irene (Department of sciences of antiquity, Sapienza University of Rome, Italy; Department of chemistry and industrial chemistry, University of Pisa, Italy) - Nardella, Federica (Department of chemistry and industrial chemistry, University of Pisa, Italy) - Mattonai, Marco (Department of chemistry and industrial chemistry, University of Pisa, Italy) - La Nasa, Jacopo (Department of chemistry and industrial chemistry, University of Pisa, Italy) - Ribechini, Erika (Department of chemistry and industrial chemistry, University of Pisa, Italy)

The history of adhesives is closely linked with the history of humankind since joining together two different parts to obtain a composite tool was a huge step forward in the evolution of Prehistoric men [1], [2]. However, over the years, the base material, typically resinous substances, required improvements. For that aim additives, such as ochre and beeswax, may be added to manipulate adhesive performance [3], [4]. Given that it is not only important to identify the constituents but also to understand how they interact with each other. This could bring information on the production techniques, giving valuable insights into the environmental, technological, and cultural contexts of ancient societies. Another important aspect to explore is the investigation of the chemical degradation of such adhesives due to natural aging. Obtaining information on the changes that occur in material over time could allow us to obtain more instruments for its preservation and restoration. To fulfill the objectives, a chemical-analytical approach mainly based on pyrolysis and mass spectrometric instrumentations will be needed. In addition, a "bottom-up" approach, starting with the study of the simplest substances, up to more complex systems and archaeological samples.

6 DEBONDABLE ADHESIVES: AN ARCHAEO-INSPIRED ADHESIVE FOR MODERN APPLICATIONS

Aleo, Alessandro (Delft University of Technology, Faculty of Mechanical Engineering; Leiden University, Faculty of Archaeology) - Langejans, Geeske (Delft University of Technology, Faculty of Mechanical Engineering; University of Johannesburg, Centre for Anthropological Research)

Here we present the first results of an industrial project where ancient materials provide inspiration for future applications. The BiDebA (Biobased Debondable Adhesives) is an interdisciplinary 'Interegg' project. Together the project partners aim to develop a solution for circular composite repair by engineering bio-based adhesives, derived from renewable resources, to facilitate effortless detachment of parts on command. Adhesives hamper recycling, consider the fastening of components in car batteries and the difficulty of repairing glued composite materials. Our approach draws inspiration from archaeological and historical materials and integrates recently developed bio-based adhesive formulations into existing pilot-scale debonding and composite repair setups. In this contribution, we present an overview of archaeological and historic debondable adhesives: the material composition, their application and material properties. We discuss how and when debondable adhesives were used in the past to resolve issues of recycling and repair. In addition, we discuss the test results of resin and starch based adhesives and a range of additives from international and standardized lap shear impact tests. Our results will be incorporated in the further activities to fine-tune the debondable adhesive for the industrial demonstrator.

7 IDENTIFYING PREHISTORIC TARS

Langejans, Geeske (Delft University of Technology; University of Johannesburg) - Aleo, Alessandro (Delft University of Technology) - Chasan, Rivka (University of Turin) - Fajardo, Sebastian (Leiden University) - Kozowyk, Paul (Delft University of Technology)

Adhesives have been an integral component of human technology for hundreds of thousands of years. The earliest Middle and early Upper Palaeolithic European adhesive finds consist of birch tar, conifer resin, and potentially tree gum, pine wood tar appears a later invention. In this paper we discuss and review possible lines of evidence for identifying tar during the Palaeolithic and Mesolithic in Europe. We review how birch and (pine) wood tar can be produced and how potential archaeological production features may be identified. Using these data we argue that it is implausible that Mesolithic hearth pits were used as tar pits, as they are sometimes hypothesised to be. Another way to identify ancient adhesives, and perhaps even their production techniques, is through spectrographic and molecular analysis of their constituents, like biomarkers such as retene and betulin. The data from such analyses, however, rarely provide straightforward results. We also consider the material properties of tars in terms of strength and durability, and we show that birch tar may have been a preferred material over resin products. Finally, we stress the importance of (experimental) knowledge of the production processes and the importance of a molecular comparative collection when interpreting the archaeological record.

8 THE POTARCH PRODUCTION IN THE BIELSKA PLAINE (NORTHERN-EASTERN POLAND). A CASE STUDY OF THE BIAŁOWIEŻA PRIMEVAL FOREST AND BEYOND

Szubski, Michal (Cardinal Stefan Wyszyński University in Warsaw) - Szubska, Magdalena (Cardinal Stefan Wyszyński University in Warsaw)

The development of remote sensing methods, especially airborne laser scanning, has contributed in the increased interest in mounds of various forms and functions occurring in landscapes. In the past, the form of these mounds was often interpreted by archaeologists as barrows. When we began intensive studies of these features in the various forests, it turned out that the majority of them are associated with production of a charcoal or a tar in the past.

In recent years, we conducted research in the Bielska Plain (north-east Poland), an area of 2740 km² which is covered in more than 30% by forests. Within this area is located the massif of the Białowieża Forest – one of the oldest forests in Europe. On this area, through remote sensing, 1890 mounds of various forms were located. The exceptional level of protection, and consequently, the very good state of preservation of the features, allowed the study of the mounds and an attempt to identify their function. Using various statistical and spatial methods, we attempted to categorize the morphological types of mounds and connected them in terms of functionality. During the research, we also conducted excavation reconnaissance of two charcoal kilns and a tar kiln.

Studies in various parts of Poland showed that the number of PoTaRCH features are usually dozens or hundreds in one forested area. On a national scale, there are thousands of such monuments, leading to both research and heritage management challenges.

9 RESEARCH ON CHARCOAL BURNING PLATFORMS IN THE CZECH REPUBLIC. METHODS, RESULTS AND PERSPECTIVE

Dejmal, Miroslav (MUNI - Ústav archeologie a muzeologie) - Příbylová, Michala (Archaia Brno z.ú.) - Šimík, Jakub (Archaia Brno z.ú.) - Houška, Jakub (The Silva Tarouca Research Institute) - Brejcha, Roman (National Heritage Institute)

Charcoal burning was one of the most important forest crafts. To the present day, artificial charcoal burning platforms are the evidence of the charcoal burning activity. There is a huge number of them in the forests of the Czech Republic and so far they have been only sporadically excavated archaeologically. Currently, these relics of historical production activities are being destroyed on a large scale by calamitous logging caused by the bark beetle. The platforms are not only an archaeological relic, but also contain an important paleoecological record and are also part of today's ecosystem.

As part of our earlier multidisciplinary project, we were able to investigate five sites across the Czech Republic. This large-scale project has allowed us to investigate charcoal burning platforms using many common and less common research methods.

The paper evaluates the contribution and limitations of individual research methods that were used. It attempts to summarize the findings obtained so far during the research of historical charcoal burning in the Czech Republic. And finally, it sets out the possibilities and challenges for the future research of charcoal burning.

10 "CHARCOAL FOR CHARLEMAGNE" - FUELWOOD EXPLOITATION, IRON MINING AND EMERGENT ELITES IN THE YOUNGER EARLY MIDDLE AGES (C. 700-1000 AD)

Lebsak, Michael (Albert-Ludwigs Universität Freiburg; Institute of Archaeology of the Czech Academy of Sciences, Brno; Masaryk University Brno)

This presentation explores the economic transformations of the younger Early Middle Ages (c. 700-1000 AD), focusing on archaeological case studies from Northern Bavaria, Germany, as a significant mining region. Iron played a multifaceted role in the given period, serving as the backbone for agricultural activities, infrastructural elements such as bridges and ships, and the military expansion of emerging elites. Therefore, the economic significance of iron was an important driver of political decision-making.

Central to the iron economy was the intensive utilization of charcoal as a primary fuel source for both smelting and processing. Recent archaeological excavations in the Upper Palatinate region in Northern Bavaria have yielded evidence for an intensive iron industry and moreover a rich anthracological dataset from pyrometallurgical devices, charcoal pit kilns and regular settlement features. This source provides valuable insights into the Early Medieval paleoenvironmental conditions, but also in the metallurgical chain and fuelwood consumption, even if it often derives from rescue excavations without targeted sampling strategies.

The dynamic environmental impact of iron mining and fuelwood production is in the present context emphasized as not being an historic necessity, but an effect of interdependent economic choices between elite and non-elite actors. Integrating anthracological data with other environmental indicators and archaeological-historical sources enhances the understanding of medieval economies and the socio-ecological contexts that shaped them.

11 PAST CHARCOAL MAKING REMAINS IN CURRENT OLD-GROWTH FORESTS HIGHLIGHT PAST HUMAN ACTIVITY IN THE FRENCH PYRENEES AND ROMANIAN CARPATHIANS

Py-Saraglia, Vanessa (Université de Toulouse-CNRS GEODE UMR 5602) - Saulnier, Mélanie (Université de Toulouse-CNRS GEODE UMR 5602) - Burri, Sylvain (Université de Toulouse-CNRS TRACES UMR 5608) - Larrieu, Laurent (INRAE, UMR DYNAFOR & CNPF-CRPF Occitanie) - Poirier, Nicolas (Université de Toulouse-CNRS TRACES UMR 5608) - Labbas, Vincent (IRPA-KIK/Université de Liège)

Recent historical ecology research carried out in six of the best-preserved old-growth fir-beech forests in the Romanian Carpathians and French Pyrenees has revealed evidence of past human activity. These forests, located far from villages and on steep slopes, were exploited for timber, but also crossed by herds and used for grazing. An archaeological survey has also revealed numerous remains of charcoal production, including in some hard-to-reach areas. According to radiocarbon dating, charcoal production dates back to the early Middle Ages, and developed mainly in modern times. This production was probably based on the valorisation of the remains of logging activities. This hypothesis was tested by charcoal analysis combined with charcoal diameter reconstruction and tree ring growth pattern analysis. The results show that both fir and beech were harvested. In the Romanian Carpathians, spruce was also used, as well as yew, which is known to be very harmful to most livestock. The results also suggest that this activity was not solely related to logging, but may have been carried out in conjunction with silvo-pastoralism.

1083 BIOGRAPHY, PERSONHOOD, POLITICS, ANCESTRY AND LUCK: THE ARCHAEOLOGY OF LIFE PATHS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Robb, John (University of Cambridge) - Thompson, Jess (University of Cambridge) - Tafuri, Mary Anne (University of Rome "La Sapienza")

Session format: Regular session

A human biography implies both a cultural ideal of what a human life (and afterlife) should be and an individual's particular pathway through it. This is so whether we are considering a Neolithic person dying and becoming a remembered, sentient ancestral presence, a Bronze Age person performing roles such as warrior or authoritative senior woman, a Roman politician amidst the *cursus honorum*, a medieval person anticipating purgatory, and for that matter, a student contemplating the narrow pathway to senior academic. Moreover, biographies involve politics and power: how to become a valued social person of a particular kind. They thus combine ideas about gender, experience, value and power with strategic planning and luck. How are biographical figures such as leaders, ancestors or knowledge specialists the focus of power or political action? How do they cope with contingency, health, intersectionality and gendered lives, mobility, and the slings and arrows of outrageous fortune?

This session explores the nexus of personhood and life narratives, political life and contingency. While these issues overlap, their connections haven't been explored. The other aim is to bring together different fields participating in the discussion. These issues have been explored in areas as diverse as osteobiography, diet and mobility, kinship, health and disability, varying lifeways, memory and monuments, gender and leadership, and iconography. But each of these themes discuss aspects of how people shape their lives and how human lives unfold; how do they speak to each other?

ABSTRACTS

1 SPECTACLE AND AUTHENTICITY IN FORENSIC BIOHISTORY

Duncan, William (ETSU) - Stojanowski, Christopher (Arizona State University)

Over the last two decades there seems to have been an increase in what can be called historical forensic cases in popular media, cases in which specialists were called on to provide a positive identification of an historical personage, characterize some facet of their life or death, or using past remains to characterize aspects of an historical incident. These have ranged from the internationally sensational (Richard III) to the regionally relevant (Pedro de Corpa, a martyred priest from Georgia). This type of work has been called forensic biohistory, and over the last decade we have attempted to explore and define the nature of forensic biohistory as a framework for engaging past bodies. Here we briefly characterize forensic biohistory, its research agenda, scope of work, and unique ethical issues that are endemic to such work. We also present the results of a survey of more than 200 cases to identify themes that run through bi-historical forensic research. Spectacle and authenticity undergird many of the cases that we found. Historical narratives that involve violence, criminality, royalty, or other sources of fame frequently drive inquiry in biohistorical work. At the same time, misinformation is an increasingly glaring problem for public discourse, and the need to validate narratives surrounding the past as authentic has never been higher. Bodies above all are undeniably indexical (in the Peircean sense) for personhood, and as such have singular potential for validating some narratives as true or authentic. We suggest that the interest in forensic biohistorical cases is thus driven in part by both spectacle and authenticity.

2 AFTER THE LBK LIFEWAYS PROJECT: REFLECTIONS A DECADE LATER

Bickle, Penny (University of York) - Whittle, Alasdair (Cardiff University)

Some 10 years ago, with many collaborators, we completed an extensive research project aimed at combining isotopic data, osteological analysis and funerary practice to explore diversity in the lifeways of the earliest farmers in central Europe. Focused on the Linearbandkeramik culture (LBK, c.5500–5000 cal BC), the results suggested widespread similarity in diet (in line with the common perception of LBK uniformity) and generally a greater lifetime mobility for females than males. Yet interesting variation in the data beyond this appeared at the scale of lifeways, when health, diet, mobility and burial rites were combined in individual biographies. Females may have moved more than males, but not always in the same way, with the same outcomes. Our aim with this reflective paper is to consider critically what our "lifeways" approach revealed about the lives of LBK communities and individuals. The patterns that appeared could not easily be explained by singular models, such as unified practices of gender, kinship or status, but could only really be made sense of as the histories of individual lifeways - the kinds of messy contingency experienced in everyday contexts. This made writing broader narratives more challenging, with headline findings which captured some, but not all, of the variation often dominating the discussion, and the conclusions other researchers took on board. We particularly address how diverse timescales, genders and kinship might have intersected for early farmers, in a social

nexus composed of multiple allegiances and alliances, ranging from households to much wider networks. Finally, we ask how individual lifeways contribute to building better models of LBK sociality, at varying scales, and to the understanding of more detailed LBK histories.

3 NARRATIVE BODIES AND PERIOD LIVES: CHANGING BIOGRAPHIES IN PREHISTORIC EUROPE

Robb, John (University of Cambridge)

Biography is often conceptualised atheoretically as simply telling a person's life story from whatever materials – skeletal, textual, or material culture – are at hand, and as something archaeologists do to create "human interest" stories. But biography is both more complicated and more important than that. Biography provides a normative narrative of what a human life should be; this gives people an interpretive framework for understanding their own lives, a motivational impetus, and a means of integrating people into larger stories of social groups and histories. Biography involves a process of self-objectification which happens through practical activity, but also through material culture and ritual occasions such as life events.

One implication of this is that biographies are cultural narratives as well as individual lives, and they vary historically. A human life story in modern, medieval, or prehistoric times had different parameters – what was "human"? when did life begin and end? What were the important qualities and events in it? We thus need to imagine biographies in terms of period lives, lives told appropriately to their cultural context; and how people in different historical moments constructed biographies tells us a lot about cosmology, personhood and politics.

This thesis is illustrated briefly by contrasting life narratives in prehistoric Italy, as known through bioarchaeology, funerary archaeology and material culture, particularly between the Neolithic and the Bronze Age when new forms of political personhood were dramatized and enacted in different kinds of life stories.

4 LIFETIME IDENTITIES AND BURIAL PATHWAYS IN COPPER AGE ITALY

Daniele, Annamaria (Sapienza University of Rome, Department of Antiquity) - Recchia, Giulia (Sapienza University of Rome, Department of Antiquity) - Dolfini, Andrea (Newcastle University. School of History, Classics and Archaeology.)

The paper explores the nexus between lifetime identities and burial pathways in Copper Age Italy based on a re-examination of 4th and 3rd millennium BC cemeteries from northern and central Italy. It has long been noted that, in the 4th millennium BC, formalised burial customs emerge throughout Italy, in which a broader section of the community is given access the grave than in the Neolithic period. It has also been noted that the funerary identities laid out in the grave focus on neatly defined lifetime gender and age identities, and in some cases, to new emerging socially distinct figures. However, little has been said regarding the nexus between social biographies, death circumstances, and the burial pathways available to the deceased. Three elements of this complex nexus will be brought to the fore in the paper: (1) the relationship between the living community and the community of the dead; (2) warrior identities and the 'biographies of violence' that may have defined their lives and deaths; and (3) the relationship between gender and age identities, burial treatment (e.g., articulation, disarticulation, and grave furnishings), and warrior burials, including occasional inversions of the accepted social norms. By exploring these life and death pathways, the paper aims to generate new insights into Copper Age Italian communities at the nexus between individual biographies and broader social identities.

5 ACTIVITY-RELATED SKELETAL CHANGES AND FUNERARY TREATMENT AT POPŮVKY (BELL BEAKER PERIOD, CZECHIA)

Ryan-Despraz, Jessica (University of Bern, Switzerland; Moravian Museum, Czechia) - Milella, Marco (University of Bern, Switzerland) - Lösch, Sandra (University of Bern, Switzerland) - Tvrđý, Zdeněk (Moravian Museum, Czechia)

Recent excavations from 2017-2019 in Popůvky revealed the second largest known Bell Beaker cemetery (3rd millennium BCE) in Moravia complete with 82 burial pits containing the remains of 75 individuals (67 inhumations and 8 cremations). Funerary treatment at Popůvky is heterogeneous and represented by varying degrees of material "richness", including prestigious child burials and evidence of kinship. Previous analyses evaluated demographic patterns and highlighted the presence of stress markers, some of which could be linked to nutrition. This study expands on this vast work by evaluating asymmetries and enthesal modifications of the humeri in an attempt to further explore the labor patterns and lifestyles of this population. These first results performing multivariate modeling of measurement data and enthesal scores suggest correlations between humeral morphology (e.g. "robusticity"), specific types of grave goods (e.g. archery-related items), and burial "richness". These results indicate an intriguing relationship between in vivo biomechanical stress, specific activities symbolized by grave inclusions, and patterns of social differentiation expressed by funerary variability. Continued research will explore additional patterns with regard to nutrition as well as comparisons with individuals from the nearby, contemporary cemetery of Hoštice 1 za Hanou. These findings contribute to a nuanced understanding of the lives and practices of the Popůvky Bell Beaker community, offering

valuable insights into the relationships between funerary treatment, skeletal manifestations of physical activity, and daily life.

6 MUMMIES ON THE MOVE: KINSHIP AND MOBILITY IN EARLY BRONZE AGE CENTRAL EUROPE

Rebay-Salisbury, Katharina (University of Vienna)

Archaeogenetic analysis can provide insights into biological relatedness, especially when combined with osteological and archaeological context analysis. This can help us understand social aspects of the Bronze Age. While genetic relatedness is important for kinship across cultures, meaningful social relationships emerge through enactment. Personal, emotional ties and social status can be expressed in the way bodies are handled, treated, and related to each other after death.

Isotope analysis has contributed to understanding mobility during the life course, but it has limitations in detecting changes in residence after adolescence. Furthermore, the issue of mobility after death has not been adequately addressed yet. In early Bronze Age Central Europe, there were high levels of post-funerary manipulations of human remains, suggesting that bodies were moved and reintegrated into the communities of ancestry. This challenges the assumption that cemeteries represent communities of people who lived together.

Based on the study of the cemetery of Drasenhofen in Austria dating to c. 2000 BC, this contribution will explore how the bodies of mothers, in particular, were subject to post-funerary manipulation and movement, highlighting the significance of the mother-child relationship in the life narrative of adults.

7 FLUID STATUS, MOBILE LIFE: A BIOGRAPHY OF THE DIVINER 'JUE' AT YINXU

Wu, Mengyang (Institute of Archaeology, Chinese Academy of Social Sciences; Department of Anthropology, University of British Columbia)

Identity cannot be assumed as a static category. As people go about their everyday lives, identities are constantly being formed, reinforced, and transformed. Thus, different sources and methods reveal “different aspects of someone” (Robb et al. 2019). The “person of interest” was the principal dead of Tomb M103 at Yinxu, the last capital city of the Shang dynasty (ca. 1250-1046 BCE). This tomb was fortunately not looted, while most of the large tombs went through a long history of looting or did not preserve skeletal remains owing to the burial structure. The burial yields direct material records and bronze inscriptions about the deceased’s status and social interaction in the Late Shang society. The nearly 50 pieces of deciphered inscriptions provide references to understanding his role and service at the court. The tomb owner is thus identified as the earliest known court diviner in East Asia, whose name ‘jue’ was frequently mentioned in oracle bone inscriptions during the reign of King Wu Ding.

By employing a multiscalar biography approach (Torres-Rouff and Knudson 2017) integrating archaeological, epigraphical, and multi-isotopic analysis (Sr, O, S, C, and N), this research offers different lines of evidence on the tomb owner of M103, including lineage name, sex, occupation, general status identification, dietary condition, origin, and mobility. Furthermore, these findings serve as a starting point for discussing how his identities were formed and implicated in the process of early urbanization at Yinxu. The diviner may be part of the “middle class” endowed with specialized, esoteric knowledge (M. L. Smith 2018, 2020), leading to a rethinking of the social dynamism of the Shang beyond the ruling elites and commoners. With the reconstruction of this individual’s biography, I highlight the recognition of diverse forms of mobilities in understanding how people congregated and were recombined over the city’s growth.

8 SOCIAL BELONGING AND RELATEDNESS AT THE RISE OF THE GREEK CITY-STATE: GENETIC EXPLORATION OF AREA 3 FROM THE HALIEIS NECROPOLIS

Tiliakou, Anthi (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck-Harvard Research Centre for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany) - Fabricius, Johanna (Institut für Klassische Archäologie, Freie Universität Berlin) - Schlehofer, Jenny (Niedersächsisches Landesmuseum Hannover) - Papadimitriou, Alksestis (Ephorate of Antiquities of Argolida, Hellenic Ministry of Culture and Sports, Greece) - Kossiva, Aggeliki (Ephorate of Antiquities of Argolida, Hellenic Ministry of Culture and Sports, Greece) - Bianco, Raffaella (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck-Harvard Research Centre for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck-Harvard Research Centre for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany) - Stockhammer, Philipp (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck-Harvard Research Centre for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany; Institute for Pre- and Protohistoric Archaeology and Archaeology of the Roman Provinces, Ludwig-Maximilian-University Munich) - Mittnik, Alissa (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck-Harvard Research Centre for the Archaeoscience of the Ancient Mediterranean (MHAAM), Leipzig, Germany)

Whereas “kinship” or “family” have long been understood as biologically determined institutions, recent research has shown that these concepts are highly dynamic and vary greatly depending upon cultural contexts with both biological and social aspects being crucial for their understanding. When it comes to the Archaic-Classical Greek communities (ca. 800-490/490-323 BCE), scholars seem to mostly examine kinship ties through a prism that connects the formation of identities to the emergence of the polis and an increasingly structured social context, with its focal point being the “oikos” (i.e., household). Topics of discussion that arose from archaeological research were for example the place of the child within the community after death, the connection of status to the mode of burial treatment, and the post-marital burial place of women within a community. The majority of research weighs upon the Athenian model – or its comparison to the Spartan – for which more written information is available. In the current study we explore the genetic relatedness within a group of burials from a part of the Halieis necropoleis, situated in the rural landscape of the Greek Argolid. Taking under consideration the good level of preservation and documentation, Area 3 was selected containing 28 graves with 30 burials from which 25 individuals were sampled for ancient DNA analysis. Our questions address whether genetic ancestry and biological kinship might have weighed upon the formation of individual/group identities, marital ties and consanguineous relationships, and how these might be reflected in the spatial organization of the burial grounds and the preference of certain burial practices over others.

9 LIFE PATHS OF THE PARAHUMAN: ROMAN ENSLAVED, ASSEMBLAGES, AND DIASPORIC PERSONHOOD

Mol, Eva (eva.mol@york.ac.uk)

In this paper I want to explore the nexus of personhood and life narratives of Roman enslaved through the lenses of parahumanity and human-spirit-object assemblages. The Roman enslaved are an incredibly diverse group, with a plethora of integrated roles in societies: from teachers, doctors, and domestic servants to industrial and agricultural work forces, derived from all over the Empire. Through the reading of Roman sources, we also learn that the enslaved as a group were not always perceived as fully human, sometimes considered ‘speaking tools’ rather than humans (Varro, *Res Rusticae* 1.17). They were ‘fungible things’ (Joshel 2011): exchangeable, replaceable, substitutable and could be turned to items for sale or a repayment for loans.

Such ‘Otherness’ had an effect (Mol 2023). It occasionally set the enslaved apart from the ‘human’ into the domain of the parahuman (Allewaert 2013), drawing them into different exchanges with objects. By paying attention to how their life paths could sometimes be forced in fundamentally different trajectories from non-slaves (spatially, temporally, and materially, through kinship and representation), we can receive a new sense of the diasporic personhoods that emerged within this social category.

10 BIOMOLECULAR ANALYSIS OF A ROMAN BURIAL FROM RURAL CAMBRIDGESHIRE REVEALS AN EXTRAORDINARY HISTORY OF CHILDHOOD MOVEMENT ACROSS THE EMPIRE

Booth, Thomas (Francis Crick Institute) - Silva, Marina (Francis Crick Institute) - Anastasiadou, Kyriaki (Francis Crick Institute) - Moore, Joanna (Durham University) - Walker, Don (MOLA (Museum of London Archaeology)) - Kelly, Monica (Francis Crick Institute) - Smith, Alex (MOLA Headland) - Bowsher, David (MOLA (Museum of London Archaeology)) - Montgomery, Janet (Durham University) - Skoglund, Pontus (Francis Crick Institute)

Excavations near the village of Offord Cluny in Cambridgeshire, UK by MOLA Headland in advance of the National Highways A14 Road Improvement scheme uncovered a single, isolated and unaccompanied skeleton of a person who had died in their early 20s and was buried in the ditch of a disused trackway not far from a Roman farmstead. We radiocarbon dated the skeleton to 126-228 cal. CE, in the Early-Mid Roman period. We sequenced their whole genome to ~4.12x coverage, which indicated that they were karyotypically male and carried genetic ancestries that were atypical of Roman populations of Britain, but instead comprised a mixture of ancestries related to Roman-period populations from present-day Armenia and Sarmatian-associated groups. Oxygen stable isotope analysis of their tooth enamel was consistent with a childhood origin outside of Britain and analysis of incremental carbon and nitrogen found that his childhood diet included high levels of C4-plants, consistent with a Caucasus or Pontic-Caspian location, and at least two episodes of dietary change. These results provide an impression of an extraordinary biography involving one person's childhood movements across the breadth of the Roman Empire. Was he enslaved, the son of a Sarmatian soldier caught up in the fall-out of the Marcomannic wars, or part of a Sarmatian cavalry unit? Was he embedded within the rural community who buried him or considered apart from them? Precise biographies will always be elusive requiring us to consider multiple possible narratives.

11 UNTOLD STORIES: 'BODY-OBJECTS', POLITICS, AND PERSONHOOD IN LATE PREHISTORIC SCANDINAVIA

Eriksen, Marianne Hem (University of Leicester; ERC StG 'Body-Politics') - Tollefsen, Emma (University of Leicester; ERC StG 'Body-Politics')

Some humans experience life trajectories that, through their situation in the social fabric, gender systems, and structures of power, as well as their health, physical disposition, and happenstance allow a pathway for them to become valued social persons, perhaps venerated leaders, ritual specialists, infamous warriors or later, ancestors. Others' lives are cut short, perhaps in childhood prior to becoming social individuals, or theirs were never fully recognised as lives at all: they emerged from circumstances where they were never going to be understood as valued social persons.

While the former figures are the well-known players of the grand narratives of the past, the latter are routinely written out. Bodies broken apart, not given formal burial, disappeared, dismembered, or turned into things — how do these 'body-objects' — somewhere on a continuum between object and subject — fit into understandings of larger social and political structures? In this paper, the inevitably partial and fragmentary biographies of such body-objects from Scandinavian late prehistory are presented, based on ongoing research of the BODY-POLITICS project. These are the untold stories of those who didn't end up in furnished burials with identities constructed through elaborate grave good assemblages, those who do not easily slot into the expected, bounded identity categories of Iron and Viking Age societies. How do these lives connect to larger questions of politics, personhood, and life narratives?

12 FROM LIFE PATHS TO DEAD COMMUNITIES. IDENTITIES AND BELONGING AT FIRST MILLENNIUM SCANDINAVIAN CEMETERIES

Arentz Ostmo, Mari (Department of Archaeology, Conservation and History, University of Oslo)

In First Millennium Scandinavia, mortuary topographies disclose dispersed burials and clusters of monuments bound to individual farmsteads and vast cemeteries used by wider communities. Cemeteries that display repeated use over centuries formed focal points in socio-political landscapes, as the loci for the transitions from living social relations to members of a community of dead bound to the same place of interment. Understanding burial practices as integral for the self-definition of communities, the burial sites also involve the negotiation of social order, social roles and relations amongst the living.

Cemeteries allow for explorations of both individual aspects of identity in terms of accentuated or under-communicated social roles and connections, alongside formations of shared, local practices within cemeteries involving body treatment, monument construction or the selective deposition of artefacts. Reiterated symbolic, ritual and material expressions may have become part of technologies of remembrance that served to anchor shared narratives and a sense of belonging to a wider community. The trajectories within enduring cemeteries then emerge as complex biographies binding together individuals and collectives, rooted in processes of forgetting and remembrance.

In this paper I will address the dynamic relationship between the individual and collective as these dimensions of identity emerge in burial practice. The political dimension lies in the stressing of what social roles were deemed significant

and thus appear likely to have political influence. I proceed to question whether different (gendered) social roles are stressed in burials located in cemeteries bound to individual farmsteads compared to large cemeteries for wider communities.

13 A LITTLE KNOWLEDGE IS A DANGEROUS THING: INTEGRATING BIOMOLECULAR ANALYSES TO RECONSTRUCT LIFE HISTORIES IN EARLY MEDIEVAL SCOTLAND

Koster, Lucy (School of Geosciences, University of Aberdeen) - Britton, Kate (School of Geosciences, University of Aberdeen) - Czére, Orsolya (School of Geosciences, University of Aberdeen) - Dittmar, Jenna (Anatomical Sciences, Edward Via College of Osteopathic Medicine (VCOM)) - Silva, Marina (Ancient Genomics Laboratory, The Francis Crick Institute) - Booth, Thomas (Ancient Genomics Laboratory, The Francis Crick Institute) - McCabe, Jesse (Ancient Genomics Laboratory, The Francis Crick Institute) - Curtis, Neil (Museums and Special Collections, University of Aberdeen) - Skoglund, Pontus (Ancient Genomics Laboratory, The Francis Crick Institute) - Girdland Flink, Linus (School of Geosciences, University of Aberdeen; School of Biological and Environmental Sciences, Liverpool John Moores University)

Biomolecular analyses, alongside other archaeological data, provide snapshots into particular aspects of the lives of past individuals from a specific angle and at a defined scale. Analysis of aDNA, dietary isotopes ($\delta^{13}\text{C}$, $\delta^{15}\text{N}$, $\delta^{34}\text{S}$), and mobility isotopes ($\delta^{18}\text{O}$, $87\text{Sr}/86\text{Sr}$, $\delta^{34}\text{S}$) regularly address similar concepts, but from different perspectives. The increasing integration of biomolecular approaches highlights the fluid and contextual nature of these concepts, and also the need for greater discussion on how different data feed into interpretations of the life histories of past individuals and communities. This is especially true when these interpretations are applied to broader questions such as those surrounding mobility, kinship and relatedness, and status.

This presentation will discuss the complexities of integrating multiple types of data in relation to biomolecular results from eighteen individuals from Lochhead Quarry, an early medieval (5th to 7th century cal. CE) long cist cemetery in Angus, Scotland. Previous interpretations of the site have suggested that it may represent a family or community burial ground, potentially associated with the documented shift towards Christianity in the region. Strontium and oxygen isotope data is consistent with lifetime mobility both within and outwith Pictland, and current data indicates a lack of close genetic relatedness in the individuals buried at the site. However, stable isotope dietary data shows a lower protein intake than the majority of contemporary populations, which could indicate that these individuals were of a lower social status than other analysed groups. Sulphur isotope ratios are also consistent with local residence in later life. The resultant biographies have multiple potential explanations, each with different implications for understanding the individuals interred at Lochhead Quarry in the wider archaeological context. This presentation concludes that these multiplicities and complexities of life histories should be embraced, and reductive narratives rejected as they risk misrepresenting and overinterpreting data.

14 'WHERE INDIVIDUALS ARE NAMELESS AND UNKNOWN': OSTEOBIOGRAPHY AND THE SOCIAL AGENCY OF INDIVIDUALS IN THE PAST

Knusel, Christopher (Université de Bordeaux)

In 1957, Christopher Hawkes (of the ladder of inference renown) wrote: "the most scientific and therefore the best, because the purest, kind of archaeology is the prehistoric kind, where individuals are nameless and unknown, and so cannot disturb our studies by throwing any of their proud and angry dust in our eyes" (quoted in Christopher Evans, *Historicism, Chronology and Straw Men: Situating Hawkes' "Ladder of Inference,"* *Antiquity* 72[276]: 398-404). But Hawkes over-stated the situation to make a point about the validity of studying the past without texts. Individual identities, although not often named individuals can be known from archaeological material alone. This is why, osteobiography, the bioarchaeological reconstruction of the lives and deaths of individuals from the past, is appealing. This type of endeavour is as true for historic as for prehistoric people, not only for those "without history," but even those named individuals who are said to be historical. This contribution introduces two women, an Iron Age ritualist, a medieval aristocratic heiress, and a Bronze Age "Tall Man," a mix of the historic and prehistoric, all nameless at first, but all better known and one named after analysis. The results help to reveal individual social agency in ways that could not otherwise be known.

15 ON THE INTERSECTION OF HEALTH, DISEASE, AND COMMUNITY CARE: HOW THE LIFE PATHS OF LEPROSY PATIENTS IN MEDIEVAL ENGLAND UNFOLDED

Blom, Alette (University of Basel)

Leprosy has both represented a biological and social condition, with its social interpretation fluctuating between religious punishment and praise, while the risk of infection, disease severity and impairment depends on early and late life health. Moreover, leprosaria appear to have offered a relatively comfortable life style (based on historic records), but

also upheld admission criteria, and varied in size, wealth and facilities, meaning that the institute someone ended up in – if any – significantly influenced available health and community care, dietary provisioning, and risk of impairment. Studying the variety in how the lives of people with leprosy unfolded, especially compared to those without this condition, is therefore essential to fully understand the impact of the disease in social and medical terms.

This paper will focus on 483 skeletal remains from leprosia, monasteries/friaries, hospitals and parish cemeteries with leprosy cases from across the UK. Using osteobiographical reconstructions (osteology, palaeopathology, carbon and nitrogen isotopes of early (n = 30) and late life (n = 32), pathogen ancient DNA (n = 72), radiocarbon dating and historic research), complemented by pre-existing data from the same or near-by sites, these remains have revealed a huge amount of variation in the different life available to, and lived by, people with leprosy. Overall, this analysis shows that people tended to stay local, either with family/friends or in local institutes. Within such institutes especially, patients received an adequate diet, and lived out a comfortable life with community care and a high level of autonomy. This discussion will focus on the variation, similarity and intersections in the life courses of those with leprosy in comparison to contemporary and near-by non-leprosy cases, and to each other, focusing on early life health (index of poor childhood experience), dietary variation between institutes and site types, disease severity, and comorbidities.

16 **ARCHAEOLOGICAL PERSPECTIVE TO THE LIFE NARRATIVE OF A SWEDISH AUTHOR, CATHARINA SWEDENMARCK**

Lipkin, Sanna (University of Oulu) - Kallio-Seppä, Titta (Museum of Torne Valley) - Väire, Tiina (University of Helsinki)

Through her poems dedicated to the King of Sweden Gustav III, Catharina Charlotta Swedenmarck (1744–1813) gained a respected status both in the eyes of the king and the Swedish nobility. She was one of the first Swedish female authors and wrote a play, “Dianas fest”. Our research on archives suggests that she was a strong-willed woman who resisted the clergy to build a burial chapel on the manor lands of her late husband Carl Fredric Toll (1718–1784). This was extraordinary as burials outside church premises was forbidden, but Swedenmarck was determined because burial under the church floor was not allowed either. When the chapel in Kourla, Vihti, Southwestern Finland was finished in 1786 Swedenmarck reburied her husband inside the chapel. Some other family members, including Swedenmarck herself, were buried in the chapel that we studied in the autumn of 2020. Our research on the coffins, mummified (possibly embalmed) remains, funerary attire, and the relevant archival sources has revealed life narratives of the eight individuals buried in the chapel. In this presentation we will concentrate on that of Swedenmarck’s. We will discuss her life starting from isotope analysis revealing aspects on her diet from infancy to adulthood to her choices while building the burial chapel in Kourla. We will also consider the importance of the family members buried next to her and how she self was buried. Both archaeological and historical evidence draws a narrative of an affluent noble woman, who lived according to the expectations of her own class, but also reveals aspects that may be interpreted outlining her personality and character.

17 **MAKING IDENTITY, BIOGRAPHY, AND MEMORY THROUGH COLLECTIONS OF HUMAN REMAINS**

Granato, Julia (University of Oxford)

Archaeology is concerned with constructing narratives about past peoples based on material remains such as pottery sherds or grave goods, temples or even entire cities; with the physical, bony remains of the archaeological dead, we can even more deeply connect ideas of politics, cosmologies, violence, mortuary behavior, and more with the people who would have experienced them. In many historical collections of human remains in the West, such aspects of these individuals’ identities and narratives have been stripped away, and yet their bodies remain prominent fixtures in museums and historic sites meant to represent, communicate, or demonstrate the past. Thus, this paper seeks to explore the making (or unmaking) of identity, biography, and memory through collections of human remains on display: how do we assign identity and construct narratives through these human remains? How do these remains or sites hold identity or personhood? How are they given or deprived of agency? And, most importantly, how do these ideas interact at the intersection of archaeological study, politics, monuments, memory, and the public? This paper will first explore the specific and varying circumstances of these individuals’ lives and deaths leading to their placement in archaeological contexts, collections, and eventual displays. Next, it will propose a theoretical framework to approach and understand the context, assumptions, political dimensions, and roles of human remains displayed in different settings (i.e., museums of anthropology, medical history, national museums, historic sites, etc.). Finally, it will then utilize several case studies—including most prominently the Hyrtl crania at the Mutter Museum in Philadelphia, PA, USA and the ossuary at Sedlec in the Czech Republic—to demonstrate the construction of individual, community-wide and larger narratives in the study and display of collections of human remains.

1088 **PERSISTENT INTERPRETATIONS AND CONTINUAL CHANGES. NEW THEORIES AND ALTERNATIVE APPROACHES TOWARD INTERDISCIPLINARY NARRATIVES OF THE PAST**

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Limina, Valentina (Université catholique de Louvain; F.R.S. - FNRS) - Eypórsdóttir, Elísabet Ásta (University of Iceland) - Lancini, Loredana (Université catholique de Louvain) - Møller-Nilsen, Kristin (University of Iceland) - Vyverman, Sarah (Université catholique de Louvain; Ecole Normale Supérieure de Paris)

Session format: Regular session

Ancient space was the physical and mental place where individuals lived, interacted, and negotiated identity, beliefs, and cultural practices at different levels (house, grave, temple, city, family group, community, etc). Humans actively shaped natural and cultural landscapes, facing periods of increased climate instability and famine, conflicts, and phenomena such as the advent of Christianity or the relentless scourge of the Black Death. Understanding this often-far-reaching past requires tackling the challenge of integrating perspectives from the Socio-historical and Natural Sciences. By combining various sources and methods, archaeology enables us to understand how persistence and change shaped ancient space. However, the theoretical approach to contextualize ‘Persistence’ and ‘Change’ could be challenging. The need for alternative and nuanced narratives of the past becomes evident when approaching concepts such as resilience, adaptation, resistance, and fragility in archaeological reconstructions. An insightful reflection about vocabulary, methodology, and approach to these concepts, sometimes provided by other research fields, leads to multidisciplinary discussions actively contributing to research advancement.

This session welcomes contributions that examine the ever-changing relationships between humans, animals, and their environments. We particularly encourage papers on theoretical approaches to persistence and change in archaeology from Antiquity to the Middle Ages without geographical limitations. Points of discussion could potentially include:

- How do we best engage with and activate archaeological and environmental research data from often localized cultural landscape investigations to transcend various disciplinary limitations and address the more extensive historical phenomena?
- How do we investigate ancient contexts focusing on persistence and change, exploring interactions, resilience and adaptation strategies employed in the face of dynamic processes?
- How have the vicissitudes experienced by a territory led to/conditioned changes in landscape and infrastructures
- Can a space’s immutability or change depend upon its function and symbolic meaning? Are there any links between identity formation and territory evolution patterns?

ABSTRACTS

1 **PERSISTENCE AND CHANGE: DYNAMICS OF ALPINE ROCK ART DURING THE FINAL BRONZE AGE**

Brooks, Morgan (University of Auckland; The Holburne Museum)

This paper presents the findings from a study exploring the evolution, decline and disappearance of rock art communities in the Alpine region during the Final Bronze Age (FBA ca. 1200-800 BCE). It advocates for employing an interdisciplinary framework to investigate the patterns and intra-actions shaping the formation and dissolutions of rock art assemblages and, by extension, communities during this period, shedding light on the pivotal capacities and relational dynamics shaping their development.

Drawing upon relational ontology, assemblage and community of practice theory, this paper presents a critical framework for examining the various relational aspects of Alpine rock art. It applies this approach to understand the continuities, variances, and adaptations of practice during the FBA. Through a top-down approach, the study recontextualises the broader socio-cultural elements within the rock art phenomenon and explores how the interplay of topography and human agency facilitated intense trans-regional connectivity between communities, fostering constellations of rock art practice across the region.

Building upon this framework, the paper presents two potential motivators underlying the persistence and disappearance of rock art during the FBA, drawing insights from Patricia Gongla and Christine Rizzuto’s model on disappearing communities in modern business organisations. Specifically, it explores how shifts in organisational structures and changes in knowledge domains may have precipitated and encouraged noticeable transformations in the main rock art ‘poles’ of the Alpine region (Valcamonica: eastern pole; Monte Bego: western pole).

2 PERSISTING THROUGH CHANGE: RESILIENT COMMUNITIES IN ROMAN ITALY'S MIDDLE TIBER VALLEY

Hoffelinck, Adeline (Radboud University)

Towns in the Middle Tiber Valley, located within one of Italy's most densely developed urban areas – Rome's Suburbium – experienced significant changes during the transition from Republic to Empire. This transformation, characterized by losses in urban size as well as in substantive social and economic functions, was closely tied to Rome's demographic expansion and its corresponding increasing political, cultural, and economic control over the broader Tiber Valley. Conventional narratives, relying on ancient literary accounts, brand this process as urban failure, contrasting it with Rome's success. However, archaeological evidence from these towns, providing lived experiences of these events, thus enabling to challenge this historical narrative from below, paint a significantly more complex picture: communities endured despite these regional changes, yet persisted through changing.

This paper examines these urban transformations in the Middle Tiber Valley through the prism of community resilience theory. By integrating both old and new archaeological data, particularly from the towns of Falerii Novi and Veii, this talk retraces how communities perceived, dealt with, and adapted to key regional shifts by engaging with community resources, such as social capital. Communities persisted through exploiting their capacities to change. Through this process, they reorganized their urban environments while also envisioning and producing alternative urban futures, often deviating from the normative conceptualization of urban life as defined by ancient and modern standards. This talk then also aims to question why some ancient urban changes have been defined as successful, while others have been deemed as failed.

3 RESILIENT OR ANTIFRAGILE? ON THEORETICAL APPROACHES TO RECONSTRUCT ANCIENT LANDSCAPES. THE CASE OF THE AGER VOLATERRANUS (C. 3RD BC-5TH AD)

Limina, Valentina (Université Catholique de Louvain)

The paper reflects on the impact of theoretical approaches in archaeology to demonstrate how different conceptualizations led to alternative, sometimes contradicting, reconstructions of the past. Archaeologists usually use techniques, models, and concepts borrowed from different disciplines to interpret and contextualize ancient data and their environments. Reconstructing the past is never neutral, and contemporary understandings only sometimes reproduce the past complexity but could reflect methodological or theoretical bias; thus, it is pivotal to be aware of the necessity of alternative narratives that could explain different scenarios of persistence and change.

Resilience Theory has been increasingly applied in archaeology to understand human-environmental interactions better. However, another concept can be applied to archaeology: Antifragility.

Into the broader debate on theoretical applications from the so-called 'hard sciences' in archaeology, the project RELOAD, funded by FNRS at UCLouvain, intends to answer the question: Could northern Tuscany be considered a 'Resilience' or 'Antifragility' model between the centuries 3rd BC-5th AD? Through the case study of ager Volaterranus, the paper will show how alternative historical reconstructions could be achieved by integrating different sources and theoretical approaches. In the face of the Roman conquest, the elites of northern Etruria, particularly the Volterrani ones, have been defined as 'conservative' or 'resilient' for maintaining a solid identity reflected in the territory management. However, the community of Volterra responded in an antifragile manner to change in a diachronic perspective. Indeed, its elites managed to transform disadvantageous 'geographical' and political conditions into opportunities for progressive and multifaceted integration into imperial dynamics. Thus, despite persistent interpretations of Volterra as a resilient community, antifragility could eventually answer better to its peculiar dynamics of change. However, is it possible to benefit from alternative past narratives or assess their validity? How could new concepts help in reassessing historical problems and modifying current interpretations?

4 TWO FARMS, TWO ENVIRONMENTAL LEGACIES: COMPARING SOCIAL STANDING AND ENVIRONMENTAL IMPACT DURING ICELAND'S SETTLEMENT

Eyþórsdóttir, Elísabet (University of Iceland) - Erlendsson, Egill (University of Iceland, Reykjavík) - Júlíusson, Árni (Stefansson Arctic Institute, Akureyri, Iceland) - Farnsworth, Wesley (University of Iceland, Reykjavík; Globe Institute, University of Copenhagen, Denmark)

While the timing and impact of Iceland's settlement have been investigated through palynological investigations, few studies have adopted a holistic approach to reconstructing the nuances of environmental impact in a region associated with societal standing. Using a mosaic of historical, palynological, and geological data, we develop a more detailed understanding of the environmental impact of two farms, with documented different social standing, in Svarfaðardalur, North Iceland.

This project is part of the "Two Valleys" project, which examines settlement patterns, social shifts, and environmental changes in Svarfaðardalur and Hörgárdalur valleys. It seeks a holistic understanding of temporal and spatial shifts in nature and society. This study focuses on land use, resource management, and environmental change.

Paleoenvironmental research hypotheses are influenced by historical and archaeological information. This investigation centres on the Sakka and Kot farms situated in Svarfaðardalur. The findings indicate that Sakka was settled in the early landnám phase (considered to be AD 870 to 930) in Svarfaðardalur and emerged as a sizable and prosperous farm with elevated social standing. In contrast, Kot was founded approximately in AD 1100 in Skiðadalur and held a lower social status.

Peatland profiles near the farms were palynologically analysed, showing a decline in birch woodland between 1100 and 1300 AD, later than typically observed in Iceland. The delay at Kot is likely due to its late establishment, while Sakka's late woodland decline poses challenges, yet possible links to resource management, population expansion, or methodological aspects. By comparing the two farms, the study addresses the timing and nature of human impact and environmental changes due to land use. This research illuminates the intricate interplay between human activities, population expansion, and environmental changes in the valleys. Findings highlight the importance of considering sustainability and adaptability within a larger framework.

5 DOMESTICATION AND RESOURCE UTILIZATION IN NORTHERN ICELAND - IDENTIFYING SOCIAL ADAPTATION AND (RE)STRUCTURING FROM ZOOARCHAEOLOGICAL DATA FROM FARM MIDDEN SITES

Møller-Nilsen, Kristin (University of Iceland)

This presentation explores the social (re)structuring in and around the two neighbouring valleys Svarfaðardalur and Hörgárdalur in the Eyjafjörður area in northern Iceland in the time period from initial Norse occupation through the Medieval period (c. 870-1500 AD). This time period is marked by several major events defining the era, from periods of immigration to the island, the religious conversion from Norse paganism to Catholicism around 1000 AD, and the waves of the Black Death in the 15th Century. Concurrently with this, or perhaps because of this, Icelandic society saw a shift from a seemingly egalitarian society from the initial settlement around 900 AD, to an increasingly stratified society by the end of the Middle Ages. By studying the zooarchaeological material from farm midden sites in the area, the goal is to identify changes in economic resource and subsistence use, which in turn will serve as a proxy for adapting socioeconomic structures.

This paper presents the preliminary results from such analysis from three different archaeological farm midden sites in Eyjafjörður: Staðartunga farm in Hörgárdalur, Tjörn farm in Svarfaðardalur, and the church farm site of Miðgarðakirkja on Grímsey island, with particular emphasis on Staðartunga farm. By comparing the data from the zooarchaeological analysis with historical data in Iceland and beyond, the purpose is to identify zooarchaeological markers reflecting factors acting upon society during this time. Further, this paper will attempt to address how to interpret this information in a meaningful manner. How can we best contextualise this information within appropriate theoretical frameworks, and how do we apply it to further our understanding of the various processes and factors impacting social change?

6 PULLING TOGETHER POWER, WEALTH, AND PLAGUE IN MEDIEVAL NORTHERN ICELAND: CONTEXTUALIZING INTERDISCIPLINARY INFORMATION TO THEORETICALLY INTERPRET HUMAN-ECODYNAMICS IN THE PAST

Harrison, Ramona (University of Bergen, Department of Archaeology, History, Cultural Studies and Religion) - Juliússon, Arni (University of Iceland, Faculty of Philosophy, History and Archaeology) - Hjartarson, Arni (ISOR) - Hreidarsdóttir, Elin (FSI - The Institute of Archeology, Iceland) - Olafsson, Stefan (FSI - The Institute of Archeology, Iceland) - Erlendsson, Egill (University of Iceland) - Kristinsson, Axel (Reykjavik Academy, Iceland) - Brynjólfsson, Sveinn (Icelandic Met Office) - Møller-Nilsen, Kristin (University of Iceland) - Eyþórsdóttir, Elísabet (University of Iceland)

The Two Valleys Project employs a Historical Ecology perspective to allow for a constructive co-production of knowledge on Icelandic settlement history and social hierarchy by identifying different scales of past human-environment interactions and their consequences.

This paper takes a first stab at activating results from the specialist-focused sub-projects which span the social sciences, the humanities, and the natural sciences. The goal is to move toward an engaged and reflective discourse to jointly re-address key questions driving this research:

How did the Black Death, this major catastrophe that hit Iceland in 1402-1404, affect various aspects of its society after a severe decline in population size? How did this change the settlement structure and the organization of land use and landownership and thus the farm-scape?

While the Black Death pandemic without doubt was a plague of pan-European scale and consequences, natural disasters such as for example volcanic eruptions and landslides also had repeated, major impacts on the population and the economy. While volcanic tephra layers serve as geoarchaeological markers of the past, landslide events are more localized and can at times provide insight into personal tragedies.

A contextualization of our multi-scalar, multidisciplinary data sets will require reflections on the following:

How can we best trace these socio-economic and natural impacts and changes, if at all? What do we think we know of these tenant farmers and their landlords? How can we approach a story about Their lives in Our attempt of fitting together multifaceted components of this research program? Can we puzzle the pieces together, and How and Why will we know and decide about When and Where they could fit?

1089 RITUAL VARIANCE IN GRAECO-ROMAN RELIGIONS: COGNITIVE AND SENSORY THEORETICAL PERSPECTIVES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Mistic, Blanka (University of Vienna) - Graham, Abigail (Institute of Classical Studies (ICS))

Session format: Regular session

Interdisciplinary scholarship on ritual practices (including from psychology and the cognitive sciences) has long upheld that a ritual act needs to maintain a set order of movements and be performed in an identical manner as in previous instances in order to be learned and transmitted effectively (e.g. Hobson et al. 2017). Recent scholarship on ritual variance (Mistic and Graham 2024), however, has put this into question, arguing that variability in ritual practices can create more memorable and more emotionally profound ritual experiences. This session seeks to explore how religious rituals and ritual experiences could shift and transform within the Roman world from one individual to another and from one generation to another, while at the same time creating a sense of continuity within a culture, a social group, and/or a religious cult. The session encourages scholars to critically (re)examine established views and material finds relating to Roman religious rituals within cognitive and sensory theoretical frameworks, in order to push disciplinary boundaries and offer novel interpretations.

We invite submissions of papers addressing, but not limited, to the following questions:

1. How can cognitive and/or sensory theoretical perspectives help us understand better ritual variance and/or ritual continuity in the Roman world?
2. How does variability in ritual practices affect learning, remembering, and/or transmission of rituals?
3. How can the study of lived ancient religion, disability, and/or neurodivergence in ancient Rome broaden our understanding of variability of ritual practices and/or ritual experiences?
4. How can ritual variance and/or ritual continuity be traced in the material record?

ABSTRACTS

1 TRANSMISSION OF KNOWLEDGE AND RITUAL VARIANCE IN THE CULT OF MITHRAS

Mistic, Blanka (University of Vienna)

In recent years, several scholars of the ancient world have turned to the interdisciplinary cognitive sciences of religion in order to explain how religious rituals were learned, remembered, and transmitted in the ancient world. Employing theoretical approaches from cognitive science of religion and sensory archaeology, this paper examines how religious and ritual knowledge was learned and transmitted among worshippers of the divinity Mithras. Archaeological, epigraphic, and iconographic evidence from the Roman province of Pannonia will be examined in order to explore the roles that persistence and innovation played in the learning, transmission, and transformation of religious ideas and behaviours in the cult of Mithras. It will be argued that social and emotional bonds between worshippers, both on a personal and professional level, facilitated the learning and transmission of religious and ritual knowledge, while at the same time fostering social cooperation and group cohesion among worshippers in the cult of Mithras.

2 THE JERUSALEM PILGRIMAGE ROAD IN THE SECOND TEMPLE PERIOD: AN ANTHROPOLOGICAL AND ARCHAEOLOGICAL PERSPECTIVE

Abadi, Omri (Hebrew University, Israel) - Marciak, Michał (Associate Professor Institute of Jewish Studies, Faculty of History Jagiellonian University in Kraków, Poland)

The pilgrimage to the Second Temple included ceremonial elements of strong spiritual significance that elevated the participants to spiritual exaltation. This ceremonial process began with the first steps pilgrims took from their homes towards Jerusalem and concluded when they reached the Temple. The paper presents the ceremonial element of the

pilgrimage in light of archaeological and anthropological research, integrated with the historical sources and with reference to the topography of Jerusalem and its surroundings (including the use of a geographic information system). These tools are used to retrace the path that pilgrims walked and present what it meant for them. The paper also investigates whether the physical act of walking can shape the pilgrimage experience, and if so, how this occurs. It is also argued that the main approach to the Temple Mount for Jewish pilgrims led from the south (via the Kidron and Ben Hinnom valleys) and the construction of this route was designed with geophysical and architectural details to enhance the spiritual experience of pilgrims.

3 PERSISTENCE AND TRANSFORMATION IN RITUALS PERFORMED IN THE SANCTUARY OF ZEUS AT OLYMPIA FROM A VISUAL PERSPECTIVE

Sassu, Rita (Unitelma Sapienza University of Rome)

In the archaeological field, research on visual culture aims, among others, to seek the relation among the [1] ancient artefacts, monuments and landscapes, [2] the viewers and [3] the messages conveyed, that acquire a specific significance in accordance with the related context. Given these premises, the paper means to focus on the sanctuary of Zeus of Olympia with the aim of investigating the switch from Greek to Roman ritual practices performed on the occasion of the Pan-Hellenic celebrations. The latter exploited the potential of visibility to display religious and athletic performances that had a high impact on the emotions and psychology of the actors involved. The papers will explore the changes occurred in Roman Olympia by analyzing [1] the new sacred landscape, that gave a primary importance to novel types monuments and dedications, starting from the honorary statues praising Roman benefactors, generals and finally Emperors, that gradually replaced the previous images of winning athletes, [2] the new Roman actors implementing rituals and religious competitions and commissioning the erections of edifices and works of art, including the Roman Emperors themselves (see, for instance, Nero). By highlighting the changes occurred, the paper will stress the elements of persistence and continuity, that were purposely maintained and skillfully exploited by the Romans. The new rules understood the potential cultural value of the site of Olympia and of its ritual tradition and used it for their political purposes to obtain an international acknowledgement, by delivering novel contents through the performance of ancient rites, now marked by slightly altered schemes and above all new significances, and the dedication of artefacts and monuments. The power of visibility in this changing scenario will be assessed, too.

4 TO BE OR NOT TO BE: ERASING DEIFIED EMPERORS AND IMPERIAL CULT STATUS IN ROMAN EPHEOS

Graham, Abigail (Institute for Classical Studies and the British School at Rome)

Erasure is often presented as a top-down and uniform practice, disseminated from Rome across the Roman world. The impact of erasure, however, was specific to a city, its urban structures, benefactors and relationship with Rome. Imperial patronage could transform a city, empowering local institutions and benefactors as well as granting privileges such as neokoros status (the right to erect a temple for imperial cult) or to hold Olympian games. When a deified emperor was condemned, the removal of his/her name was ritualistic, a process designed to separate an individual from the power he/she represented. In practise, however, it is worth considering the broader implications of erasure: how did individuals differentiate between the games and spaces of Imperial worship from the individual who granted these privileges? At Ephesos, Domitian, Commodus and Geta were associated with neokoros status and/or Olympian games, but less attention has been paid to practical considerations: what did these erasures look like and how might they have impacted perceptions of Imperial rule? Can we separate Imperial power from an emperor?

Viewing erasures as a predominantly visual phenomenon, which varied in context, appearance and outcome (e.g. visibility, legibility), this paper employs theoretical models of and perceptive processes to consider how a broader audience of ancient viewers experienced and engaged with erasures, which did not require literacy to see or understand. Building upon recent studies of perception, cognition, and variance in ancient monuments (Ng: 2019a; Ng 2019b; Graham 2021 and 2024), this paper considers the different ways that erasure could be presented within similar urban spaces and/or within the same monument, and how subsequent changes to a monument could shape the way that the viewers engaged with its meaning and messages.

5 EPIGRAPHIC VARIANCE AND THE MAKING PROCESS OF SMALL ALTARS AT VINDOLANDA

Rome Griffin, Alexander (Lancaster University)

The presence of portable altars at Roman sites in Britain is well known. However, discussion of them is often cursory, only commenting on their diminutive size and the generally 'scrappy' nature of their inscriptions and decorations. This 'scrappiness', which is often dismissed as solely the result of a skill deficit, creates visual and textual variability; little focussed work has been undertaken to understand the overall effect of this epigraphic variance. This paper will examine the corpus of altars from Vindolanda to assess how the heterogeneity of these objects created epigraphy that was

distinct from entirely professionally made pieces, thus prompting a deeper consideration of the role that audience played in structuring epigraphic objects.

Furthermore, A.C King has recently suggested that the ‘scrapiness’ of these altars is partially the result of dedicants playing an active role in creating them. Whilst fully understanding the intentions of dedicants who chose to inscribe their own altars is impossible, my paper intends to demonstrate that examining the making process from an experiential standpoint can help us to draw some broad inferences regarding its ritual significance. This approach has been successfully applied to curse tablets, which parallel portable altars in that some appear to have been written by scribes and others by the dedicants themselves. Discussion of curse tablets has suggested that writing them may have sometimes formed part of the ritual process and this paper will examine whether the act of inscribing portable altars may have been similarly perceived.

Combining these two facets will allow these informative but largely overlooked objects to be considered from new theoretical angles and will aid in creating more nuanced discussion which recognises the significance of epigraphic variability, as well as the roles of audience and experience in structuring portable altars.

6 DISCREPANT DOGS: CANINE SYMBOLISM AND RITUAL VARIANCE IN THE ROMAN WORLD

Lundock, Jason (Full Sail University)

There are few, if any, species whose story through the millennia has been so intertwined with that of humans as the dog. For this reason, canines have been incorporated in a multiplicity of roles in the ritual behaviour of humans and they offer a fruitful case-study in ritual variance and cognitive association in the construction of religious practice. This paper shall focus on the development of ritual and magic practice involving canines in the Roman world from the Late Republic to Late Antiquity, approximately 200 BCE to 500 CE, to illustrate how a symbolic association may be utilised and adapted over time to fulfil the psychological and sociological needs within a given ritual community. Archaeological and textual sources shall be utilised in this discussion, with a particular focus on the iconography of ritual objects, to illustrate how the role of the canine varied and how its symbolic association was utilised for the construction of ritual practice by a diversity of groups. Theoretical lenses from the fields of psychology and neuroscience, with a focus on cognitive associative reasoning, shall help to inform our interpretation of these behaviours and how the diversity of practice helped to create a pluralistic social identity through ritual performance in the Roman world.

1090 ARCHAEOBOTANICAL HERITAGE: COLLECT, PRESERVE, SHOW, SHARE!

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: D’Auria, Alessia (University of Naples “Federico II”, Department of Agricultural Sciences) - Speciale, Claudia (IPHES-CERCA, Catalan Institute of Human Palaeoecology and Social Evolution) - Kerfant, Céline (IPHES-CERCA, Catalan Institute of Human Palaeoecology and Social Evolution) - Matteredne, Véronique (CNRS - MNHN, UMR 7209 Archéozoologie-Archéobotanique, sociétés, pratiques, environnements.)

Session format: Regular session

The broad topic of the session is The Life of Archaeological Heritage in Society. The specific topic is the valorization of the Archaeobotanical Heritage (macro- and micro-remains) as one of the essential witnesses of the daily human activities in the past; from the wooden shipwrecks of several meters long to the phytoliths collection, archaeobotany offers a wide variety of materials and opportunities to show how humans in the past used plants for any kind of purpose. Unfortunately, even today, little interest is placed in this type of material, especially in its use for didactical, outreach and educational values in museums, universities and elsewhere. Moreover, there are very few communications about plants remains in the scientific media. We would like to invite scholars who work with archaeobotanical remains (from charred to waterlogged wood, from carpological remains to microremains) and who are involved in the valorization of archaeobotanical collections and their use for educational purposes. We would like to emphasize the difficulties associated with the classification, preservation, and valorization of archaeobotanical material and collections, also but not only the historical ones (for example, the collection from the Vesuvian area, see the National Archaeological Museum of Naples and the Archaeological Park of Herculaneum, Italy, or the collections of the Museum of the University of Tübingen, Germany, or the Museum of Vojvodina, Serbia), as well as the methods employed to make them usable and enjoyable for everyone. We encourage archaeologists and archaeobotanists with virtuous experiences in physical or digital exhibitions, educational activities for children and adults, didactical practices for university students, any kind of valorization project that allowed the archaeobotanical heritage to be well preserved and shared with the scientific community and the wide public as well.

ABSTRACTS

1 BRAIN DATABASE: A SHARED RESEARCH COLLECTION FOR EFFECTIVE AND MULTIFACETED OUTREACH OF ITALIAN ARCHAEOBOTANY

Florenzano, Assunta (Laboratorio di Palinologia e Paleobotanica, Dipartimento Scienze Vita, Università degli Studi di Modena e Reggio Emilia; NBFC - National Biodiversity Future Center, Palermo) - Mercuri, Anna Maria (Laboratorio di Palinologia e Paleobotanica, Dipartimento Scienze Vita, Università degli Studi di Modena e Reggio Emilia; NBFC - National Biodiversity Future Center, Palermo)

This paper provides an overview of BRAIN - Botanical Records of Archaeobotany Italian Network, a unique and large research network in which plant micro- and macro- remains are collected in the same database, and to which different experts can contribute. BRAIN aims at sharing the archaeobotanical studies carried out in archaeological sites and human-influenced off-sites located in Italy and some Mediterranean countries. Since 2014, hundreds of archaeobotanical metadata have been entered in BRAIN; the database reports lists of sites, their location, culture, archaeological contexts, and how many types of botanical analyses have been performed in research studies since the 1980ies. The compilation of the great wealth of archaeobotanical data from both peer-reviews scientific journals and grey literature improves our knowledge on plant-human interaction during pre-historical and historical times, and increases the impact of archaeobotanical research on recent issues such as environmental sustainability, biodiversity, nature conservation under global change. In this regard, particular attention is being paid to the long-term human-environment dynamics based on floristic data by BRAIN within the ‘National Biodiversity Future Center’ for biodiversity management and conservation planning. Plants are at the heart of BRAIN, as a paramount element related not only to nature but also to the cultural, social, technical, and symbolic realms in which humans are embedded. The vast set of data collected in BRAIN presents archaeobotany as a self-informative science; whether through searching a catalogue of sites and plants, their chronology and location, this reference database aims to increase awareness of the role of plants in human life.

Abstract implemented under the NRRP, Mission 4 Comp.2 Inv.1.4—Call for tender No.313816122021, rectified by Decree n.3175 of 18.12.2021 of Italian MUR funded by Next Generation EU. Project code CN_00000033, Concession Decree No.1034 of 17.06.2022 adopted by MUR, CUP E93C22001090001, Project title “National Biodiversity Future Center — NBFC”.

2 THE INTERNATIONAL COMMITTEE ON OPEN PHYTOLITH SCIENCE: A COMMUNITY EFFORT TO IMPROVE THE COLLECTION, PRESERVATION AND SHARING OF PHYTOLITH DATA

Kerfant, Celine (on behalf of ICOPS (International Committee on Open Phytolith Science), Universitat Pompeu Fabra)

Phytoliths are plant microfossils used worldwide to answer a variety of questions in fields as diverse as archaeology, palaeoecology and palaeontology. The result is a profusion of phytolith terms and methodologies that partially hamper commensurable communication and sharing of knowledge among research communities.

The International Committee on the Open Science of Phytoliths (ICOPS) was established in 2021 to improve this situation and start moving towards implementing open scientific principles and practices. This presentation aims to outline the objectives and achievements of this community group, which include:

The implementation of training workshops in digital tools such as GitHub for researchers and students;

the creation of a website, using the GitHub environment, designed to store and share all data relating to ICOPS actions in a transparent way;

an open publishing guide to help researchers publish and share phytolith (raw) data;

the beginnings of the first ontology for phytolith research, designed in accordance with the International Code for Phytolith Nomenclatures (ICPN 1.0 and 2.0) to facilitate the accessibility and interoperability of phytolith data;

a community survey and FAIR assessment of existing phytolith data to establish FAIR (Findable, Accessible, Interoperable, Reusable) data guidelines for phytolith research.

Future plans for 2024 include talks from experts in open and FAIR science and clinic sessions to help and support researchers to implement open and FAIR practices in their research projects and data.

3 **ARCHAEOBOTANICAL HERITAGE: THE COLLECTION OF EDIBLES AND ORGANIC REMAINS OF NATIONAL ARCHAEOLOGICAL MUSEUM OF NAPLES (ITALY)**

D'Auria, Alessia (University of Naples "Federico II"; Department of Agricultural Sciences) - Miele, Floriana (National Archaeological Museum of Naples) - Di Pasquale, Gaetano (University of Naples "Federico II"; Department of Agricultural Sciences)

The eruption of Vesuvius of 79 AD was one of the greatest disasters in ancient times, and since 1738 the archaeological sites in the area have produced large quantities of botanical remains, going to form the so-called "Collection of Edibles and Organic Remains", currently housed in the National Archaeological Museum of Naples (MANN). It is considered as one of the most extensive archaeobotanical collections from the classical world and provides in-depth evidence of Roman dietary habits. Our study provided a first comprehensive overview of the specific features of each find of these plant remains. In particular 20 woody taxa and 31 herbaceous taxa have been identified. Among these the most frequent are plants for food use: the most common cereals were *Triticum dicoccum* and *Hordeum vulgare*, while *Vicia faba* var *minor* and *Lens culinaris* were the more common pulses. Frequent are also figs (*Ficus carica*) and dates (*Phoenix dactylifera*).

Despite the high relevance and uniqueness of these ancient organic materials (so that they were included in the Precious Cabinet hosted in the Herculaneum Museum at Portici and then in the Royal Bourbon Museum in Naples) they were neglected for a long time, due to criteria and conservation methods now outdated and inadequate compared to current scientific principles. From this point of view, it would be extremely important to focus the attention of scholars and sector experts to this unique archaeobotanical collection, which constitute a cornerstone of the cultural heritage of the classical world, especially with regard to food culture and ancient landscapes.

4 **NOT SO BEAUTIFUL ENOUGH? THE ARCHAEOBIOLOGICAL HERITAGE HIDDEN FROM PUBLIC**

Celma Martínez, Mireia (University of Murcia) - Haber Uriarte, María (University of Murcia)

The archaeobiological heritage is still presented as something extraordinary in most of the museums of the Iberian Peninsula. Only those remains that present shapes identifiable by the public and the most outstanding beauty, worthy of being shown, are considered suitable to be part of the permanent collections in display cases. On the other hand, the complexity of their recovery in archaeological sites and the correct treatment that the remains must receive during their study and storage make it even more complicated for them to enter the ordinary circuit of museum objects.

The absence of sufficient representation of the organic materiality of the everyday life of the past in these contexts of didactics and heritage pedagogy encourages this type of remains to be underestimated by society. It is even extended to Bachelor's, Master's, and professional archaeologists, who tend to consider inorganic materiality as the only one capable of formally explaining the past. In this paper, we present the state of the art through a review of the organic collections exposed to the public, developing a SWOT for the Iberian Peninsula.

We consider that the results of the research must be synthesized to be shown to the public and to be able to redefine the prominent role that organic remains played in explaining the changing history of past societies. In addition, we propose a new form of integrated presentation of the Archaeobotanical and Archaeobiological remains to improve the visitor's understanding and raise awareness among the general and specialized public of the importance of these remains given the unique information they offer us.

5 **CULTURAL HERITAGE AND BIODIVERSITY OF RIETI BASIN AND PIEDILUCO LAKE: ARCHAEOBOTANICAL EVIDENCE FROM LAKESHORE SETTLEMENT OF PADULI (CENTRAL ITALY)**

Vanacore, Lucia (Department of Agricultural Sciences, University of Naples Federico II) - Virili, Carlo (Department of Science of Antiquities, Sapienza University in Rome) - Jaia, Alessandro (Department of Science of Antiquities, Sapienza University in Rome)

The archaeological site of Paduli, situated close to the shore of the Piediluco lake (Colli sul Velino, Rieti, Latium) is part of the articulated context of lakeshore settlements that populated the Rieti basin and the Piediluco lake between the early Bronze Age (20th century B.C.) and the early Iron Age (9th century B.C.). Thanks to environmental conditions, the Paduli site provided a wide range of archaeobotanical remains, including charcoals, charred seeds, and waterlogged wooden structures. The study of these materials associated with knowledge of landscape ecology has enabled us to characterize the biodiversity of this area 3000 years ago and to make some suggestions about human activities related to the forest, as well as the use and knowledge of wood resources. Specifically, our results indicate the presence of two different forest landscapes: a large planifolia forest dominated by *Quercus robur* L. (pedunculate oak) and/or *Quercus petraea* Matt. (sessile oak), and *Carpinus betulus* L. (hornbeam); a mixed deciduous forest of the hilly zone dominated by *Q. cerris* L. (Turkey oak) and *Q. pubescens* Willd. (pubescent oak) associated with *Carpinus* spp. Furthermore, the results obtained from the study of wood artifacts reflect the specific needs of local communi-

ties, suggesting that the inhabitants of Paduli were able to select tree species based on the technological properties of wood. Nevertheless, they met their wood requirements from nearby local resources. In conclusion, the dissemination and promotion of this archaeobotanical heritage through its investigation and musealisation are not only useful for forest restoration works and valorisation of the landscape but also enrich knowledge about the archaeological site of Paduli, thereby enhancing the cultural identity of the local community.

6 **DIACHRONIC RECONSTRUCTION OF THE HUMAN-ENVIRONMENTAL RELATIONSHIP AT THE UNESCO WORLD HERITAGE SITE OF BUTRINT: A NEW ARCHAEOBOTANICAL PERSPECTIVE IN ALBANIA**

Tomasini, Riccardo (Sapienza University of Rome) - Moricca, Claudia (Sapienza University of Rome) - Hernandez, David (University of Notre Dame) - Molla, Nevila (Institute of Archaeology Tirana) - Hodges, Richard (University of East Anglia) - Sadori, Laura (Sapienza University of Rome)

Butrint, designated as a UNESCO World Heritage Site since 1992, is situated in the southern region of Albania, overlooking the Vivari Channel, and facing the Greek island of Corfu. Despite archaeological investigations having started in 1928, Butrint has been minimally explored from an archaeobotanical perspective. The present study represents the first in-depth archaeobotanical exploration of Butrint that seeks to reconstruct the diachronic human-environment relationships of this important archaeological site. Thanks to the extended occupation, spanning from the Archaic to Venetian period, Butrint offers a rich selection of different archaeological contexts across different epochs, containing abundant and well-preserved plant macroremains. The remains, sampled in 2022 and 2023, are mainly preserved through charring and waterlogging. Preliminary analyses were performed on materials from medieval contexts of the Western Defences (10th century AD), and the Roman forum (3rd century B.C. to 7th centuries A.D.). These reveal an assemblage mainly composed of cereals (*Triticum monococcum*, *Triticum turgidum* subsp. *dicoccon*, *Triticum aestivum/durum* etc.) and pulses (*Vicia lens*, *Lathyrus oleraceus*, *Lathyrus* sp. etc.) at the Western Defences, while a low presence of cereals and a high concentration of *Vitis vinifera*, *Sambucus nigra* and *Rubus fruticosus* is reflected in area of the Roman forum. In terms of charcoals, the most represented taxa are *Quercus sect. robur*, *Rhamnus/Phillyrea*, *Olea europaea* and *Acer* sp. This research not only aims to fill a significant gap in the archaeobotanical exploration of the site but also contributes to broader discussions on human-environment interactions in the Albanian and Mediterranean regions. The findings are anticipated to shed light on the adaptive strategies, subsistence patterns, and agricultural evolution of the diverse communities that inhabited Butrint over the centuries, enhancing our comprehension of the intricate interplay between human societies and their surroundings.

1091 **ARCHAEOLOGY AND NATURE MANAGEMENT: FRIEND OR FOE? HOW ARCHAEOLOGICAL HERITAGE IS DEALT WITH IN NATURE CONSERVATION CONTEXT**

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Cordemans, Karl (Flemish Land Agency) - Schreurs, José (Heritage Agency) - Byrnes, Emmet (Department of Agriculture, Food and the Marine)

Session format: Regular session

In October 2020 the European Commission proposed a new legal framework on the restoration of ecosystems which was agreed on in trilogue on November 10, 2023. The regulation envisages legally binding targets, including nature restoration for 20% of EU land by 2030. Member States will have to submit plans within two years on how they will meet the targets and conduct regular monitoring and reporting. This means that member states will be obliged to step up and scale up. The large scale of projects for nature restoration and development will no doubt have a great impact on the conservation of known and as yet unknown archaeological values in nature areas and reserves. Questions to be addressed include: How is the field dealing with this? Are European (such as Environmental impact assessment) and national regulations sufficiently specific to set conditions for nature development and management activities? How can there be cooperation with nature managers? Contributions are welcomed from all countries: it would be good to have whatever examples and experiences of archaeology in relation to nature management that are out there, whether they come from Europe or wider afield. Contributions can be broad: good or bad practices (practical, legislative, ...), case studies, more ethical or philosophical reflections,....

1 HOW ARCHAEOLOGISTS VIEW NATURE? AND HOW DOES THIS REFLECT IN NATURE PROTECTION LAWS?

Žaža, Petr (Masaryk University)

Nature in archaeology is often studied either as place where history happened, or when we need to find out about the climate past societies lived in, seldom is nature taken as a part of the bigger picture, that is, the landscape. Human factor often gets lost along the way. This is also true when talking about nature management and protection. Cultural landscape is omitted from the factors needing protection as well. Even though it might seem inconsequential, does the archaeological point of view not reflect the general view of our modern society on the connection between nature and archaeological heritage? One which also reflects on the need to protect nature in the first place. Yet, in many cases, the nature around us has been created by humans in the past, and especially in Europe, very few places remain a true nature-made habitats. This opens the possibility to deal with these problems of nature and heritage protection as a more intertwined topic. The goal of this presentation is to draw attention to the problems stemming from the fragmentation of efforts when dealing with nature and cultural heritage, and how can archaeology, more precisely a shift in archaeological theory, help with the lack of comprehensive approach when dealing with archaeological heritage in projected nature management restoration efforts?

2 IN THE FIELD OF CONFLICTING INTERESTS. CURRENT CHALLENGES AT THE INTERFACE OF CULTURAL HERITAGE AND ENVIRONMENTAL POLICIES IN SWITZERLAND

Schaer, Andrea (Archaeokontor GmbH/University of Bern)

In Switzerland, archaeology is often subsumed under the concept of nature and cultural heritage protection in legal frameworks. Nature conservation and the preservation of cultural heritage thus belong together, at least at the legal level, in a way that is constantly being negotiated.

In the current political environment, which is also characterised in this country by climate and, in particular, energy debates, various, sometimes conflicting trends can be observed. In order to understand these, it is first important to differentiate between environmental concerns. The concerns of environmental protection are not limited to the protection of biodiversity and the preservation of landscapes, the latter combined with spatial planning policy endeavours, i.e. concerns that are highly compatible with the archaeological guidelines laid down in the Malta Convention. More problematic with regard to archaeological heritage conservation and the preservation of architectural monuments are the concerns of nature conservation, in particular the concerns of the energy transition. At the same time, newly developed strategies pursuing a holistic approach, such as the concept of “Baukultur” (see “Davos Declaration on Baukultur 2018”), that challenge archaeology and the whole sector of cultural heritage management and ask for new, more comprehensive but also more inclusive approaches.

In the field of tension between climate and environmental protection and the protection of cultural heritage, archaeology must position itself in such a way that it is not perceived as an obstacle or a brake, but rather as a constructive discipline that can make its own independent and important contribution.

The presentation sheds light on the current political and social debate in Switzerland and uses examples of current projects to illustrate how the tensions described above play out at legislative level and in practice, and how ways are being sought to reconcile environmental concerns with cultural heritage issues.

3 THE EU HABITATS DIRECTIVE AND CULTURAL HERITAGE LEGISLATION AND REGULATION - SOME PERSPECTIVE FROM IRELAND

Kirwan, Seán (National Monuments Service, Department of Housing, Local Government and Heritage)

As a Member State of the EU Ireland has had experience of implementing the EU Habitats Directive since its introduction in the early 1990s. The Directive (among other matters) requires authorities consenting to or undertaking plans or projects to make screening determinations as to whether a process known as “appropriate assessment” (“AA”) must be carried out to consider effects on “European Sites” (in broad terms the network of habitats protected under EU law).

This core aspect of the Directive has been implemented in Ireland through the statutory planning and development code (as regards projects covered by that code) and, as a default, through a domestic implementing regulation requiring the necessary screening (and, where applicable, AA) to be carried out by any public authorities granting consent, or undertaking, projects.

In recent years work has progressed on a completely revised and modernised code specifically directed at protection of cultural heritage, which was enacted in late 2023. The work on that legislation, and now on the administrative steps

to implement it, have brought greater focus on the need for projects licensed or undertaken under that legislation to be subject to the requirements of the Habitat Directives (in particular as regards AA, but other issues also arise). A particular example would be cases of research archaeological excavation, for which the National Monuments Service would, in the normal course, be the sole regulatory authority (and thus the body charged with ensuring the Directive is complied with). Other instances also arise.

While the detail is technical and situated in an Irish (though also EU) legal context, examination of this matter offers opportunities to reflect on the need to accept that archaeological and cultural heritage projects need to be considered as regards natural heritage impacts just as much as any other project category.

4 STRIVING FOR SYNERGY: NATURE AND HERITAGE

Young, Janine (National Trust) - Caroli, Vivivana (National Trust)

As a direct response to the climate crisis the National Trust have set ambitious targets for nature recovery, aiming to plant 20 million trees by 2030 and create 25000 hectares of priority habitat by 2025. For the Trust’s archaeological advisors this represents new challenges. How can we protect the significant archaeological remains on Trust land, whilst also facilitating this response?

Recent guidance from bodies like Natural England is beginning to address this with the recent publication of ‘Heritage in Nature Recovery’ but most sector standards are aimed at the world of development, protecting the archaeology in the face of construction and don’t provide the right tools for incorporating archaeology in nature recovery projects.

This paper uses the case study of Attingham Park, a 1000-hectare estate in Shropshire containing part of Viriconium Roman city. An ambitious 30-year nature recovery vision for the estate is being created. The potential for significant buried archaeological remains forming part of the Viriconium hinterland is substantial and remains may be threatened by creation of woodland and wetland. To inform the archaeological response a 1000-hectare magnetometer survey has been carried out to inform the vision and enable a strategy to incorporate the archaeology. We will look at what we learnt from the geophysical survey and how the results be used and incorporated into the nature recovery vision without being seen as merely a constraint.

This paper will also address wider issues faced by the National Trust Archaeological advisors when working on nature recovery schemes, giving examples of successes and failures in our approach. For example; funding considerations, extent of mitigation required, strategies to promote an integrated landscape perspective. Finally and perhaps most importantly, how can we use our understanding of the past to help build resilient landscapes for the future?

5 NATURE AND HERITAGE: HOW TO SEDUCE NATURE MANAGERS?

Schreurs, Marie-José (Cultural Heritage Agency of The Netherlands)

In the Netherlands, large-scale nature restoration and development projects are being carried out in order to meet European 2030 goals on restoration of ecosystems. In addition, climate adaptation programs will lead to measures in nature reserves. Preserving heritage is not an explicitly stated goal in these assignments. The current legislation regarding monuments forms the framework within heritage is safeguarded. However, this legislation is not specifically focused on heritage in nature reserves. This means that many nature restoration activities do not require a permit. Common activities include removing sods and other methods to remove nitrogen-rich topsoil, raising the water table and closing ditches.

Our goal is to seduce nature managers to preserve heritage beyond what is legally required. The Cultural Heritage Agency of the Netherlands has started projects to increase awareness of archaeological heritage and provide advice on its preservation. We inform owners and managers about protected monuments and other archaeological sites and the expected archaeological heritage in nature reserves. Various methods have been used: Amongst others, giving archaeology courses for project leaders and managers of the large site management organizations in the Netherlands i.e. Staatsbosbeheer (State Forestry department) and Vereniging Natuurmonumenten (Society for Preservation of Nature Monuments). Together with these organizations we examine possible alternative measures and plan adjustments to achieve nature objectives and minimize damage to archaeological heritage.

Another example is the development of an archaeology module for schools in the Dutch green sector (agriculture, nature and food).

This presentation discusses the collaboration between the various stakeholders to promote heritage awareness.

6 INTEGRATING HERITAGE INTO LAND MANAGEMENT SCHEMES IN ENGLAND

Poppy, Sarah (HE - Historic England)

December 2022 saw the publication of legally binding targets for the environment in the UK, including the reversal of species decline by 2042, restoration of water bodies and a 2% increase in tree and woodland cover by 2050 to support net zero and nature recovery objectives. Heritage is recognised in Defra’s 25 Year Plan, under the theme of

“Enhancing beauty, heritage and engagement with the natural environment”, and is reiterated as an objective in the Environmental Improvement Plan published in 2023. However, the lack of statutory targets is proving to be a barrier to heritage being recognised as a priority in scheme policy and development. Drawing on Historic England’s recent experiences with the post-Brexit Farming and Countryside Programme, this paper will outline the nature-based schemes that are being developed and introduced in England, how the heritage sector is responding to address these, and reflect on the opportunities and challenges for integrating heritage.

7 SPATIAL CHALLENGES FOR ARCHAEOLOGICAL HERITAGE MANAGEMENT IN FLANDERS

Gheysen, Korneel (Flemish Land Agency) - Cordemans, Karl (Flemish Land Agency)

Flanders is a small and crowded region. This results in many claims regarding land use. Many of these claims are induced by European policies such as Biodiversity, Afforestation and Nature restoration targets, but also Water management and the common agricultural policy have had major effects on archaeological heritage management. In the years to come, the land use pressure will even increase due to big scale nature development projects and new developments to tackle climate change by the Flemish government. In this paper an overview will be presented on how archaeology and landscape is (or is often not) taken into account in land management and new developments. It will be demonstrated that there is a big difference depending on who is taking the initiative (private and public). We take a look on how policy deals with this and how this will develop. Some good practices and possible solutions will be presented too.

8 WELL TOGETHER? CASE STUDY OF A NATURE PARK AS A WETLAND AND ARCAHEOLOGY CONSERVATION OPERATIONAL ENTITY

Brancelj, Ana (Ljubljansko barje Nature Park Public Institute; University of Savoie Mont Blanc)

The aim of the contribution is to present of case study and to discuss the practices within the legislative and management framework of a nature conservation public agency, who is responsible of a wetland archaeological site.

Nature park Ljubljansko barje in Slovenia is a nature conservation public institute and since 2008 a site manager of cultural landscape that is loosing its wetland characteristics due to centuries ongoing drainage, unadapted agricultural practices, spreading urbanisation and lack of general understanding of the wetlands importance. For the reason of a spatial overlapping, the public institute is since 2011 also a site manager of one of the a UNEESCO world heritage site of the Prehistoric pile dwellings around the Alps. These are considered as best preserved organic remains dating from prehistory, that long remained intact and are extremely well conserved due to their waterlogged environment. The loss of the wetlands characteristics not only endangers the nature, habitat and biodiversity conservation as one of the principal goals of the institute, but also archaeological remains are at stakes, for the deterioration of their waterlogged milieu. What are legal and operational possibilities of a public institute for the joint protection of the biodiversity and archaeological heritage? What obstacles and which opportunities site manager encounters, what actions were already made, and what are the perspectives?

Our aim is to present a case study of one public entity that tries, within its formal obligation, to overcome the traditional dichotomy in nature and culture conservation. We will show what strategies are used to englobe the two goals, when the administrative and legislative circumstances are yet not set in the way to make things happen or work easily.

1093 LIFE AND DEATH IN THE CELTIC WEST: NEW INSIGHTS FROM BIOARCHAEOLOGY AND FUNERARY ARCHAEOLOGY

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: O’Brien Butler, Ciara (Cardiff University) - Faillace, Katie (Cardiff University) - Hemer, Katie (University College London) - Kinirons, Samuel (University College Dublin)

Session format: Regular session

Academic use of the term “Celtic” has long been controversial, with material, chronological, and lingual critiques. These criticisms have resulted in increasingly nuanced scholarship regarding the Iron Age and Early Medieval communities (800 BCE – 1000 CE) with “Celtic” language and material culture, acknowledging regional and chronological variation. Despite methodological and theoretical developments, bioarchaeological investigations remain a minority within “Celtic” studies; reasons for this paucity vary between regions, but include poor preservation, fewer developer-funded excavations, and, for the Welsh early medieval period, a comparative lack of surviving historical sources. However, in the past decade, several new discoveries of human and animal remains from archaeological excavations has led to a boom in osteological research in Wales, facilitating new comparisons to the better-studied areas within the “Celtic” world. These excavations cover a multitude of site types including Iron Age hillforts, Viking era settlements, and early medieval cist cemeteries, greatly increasing the interpretative potential of the remains. In particular, recent investigations have highlighted the interconnectedness of regions in these periods, emphasising a shared Irish Sea

heritage, as well as building on links between the Celtic West and Scandinavia and the Mediterranean world. These relationships form the inspiration for this session, which will integrate these results into our broader understanding of the Celtic West from 800 BCE to 1100 CE and contextualise the scientific data from human and faunal remains. This session invites all papers from osteoarchaeological and zooarchaeological perspectives (including biomolecular and histological studies), particularly those which integrate the funerary evidence or explore links between regions.

ABSTRACTS

1 FEEDING KING AND COURT: FOOD RENDERS, HUNTING AND FEASTING AT LLANGORSE CRANNOG, WALES

Best, Julia (Cardiff University) - Mulville, Jacqui (Cardiff University)

Llangorse Crannog is a gem in crown of Welsh archaeology. This royal site, associated with the kings of Brycheiniog, was in use between 890 and 916 AD before being burnt to the ground. Excavation revealed a rich array of artefacts including a substantial animal bone assemblage, which is currently the largest fully analysed assemblage in Wales of this date. With bone preservation being poor in many areas of Wales, this is a valuable resource. The zooarchaeological assemblage contains a unusually high proportion of wild animals, in particular red deer (*Cervus elaphus*), alongside key domestic species such as pigs, cattle and sheep/goats. Some species having distinct sections of the body represented, and the age profiles indicate that Llangorse was a consumer site. The animal bone has given an incredible insight into hunting targets and kill sharing, as well as shedding light on the wider provisioning of the site, including the probability of renders – gifted food. When analysed alongside the Welsh law-books such as Cyfraith Hywel (the Law of Hywel) this site provides a unique window into hunting, herding, feasting, kingship and social hierarchy. This allows investigation of status, display and sustenance in early medieval Wales, and can also reveal how different groups used the animal resources to negotiate power and identity.

2 BEYOND THE BONES: THE EARLY MEDIEVAL ANIMAL REMAINS FROM LLANBEDRGOCH, ANGLESEY

Hood, Meredith (Cardiff University; Amgueddfa Cymru)

Understandings of farming systems and human-animal interactions in early medieval Wales (5th-11th centuries CE) have, unfortunately, been limited by poor survival of faunal remains and sparse historical texts. The large animal bone assemblage from the enclosed settlement at Llanbedrgoch, Anglesey (Ynys Môn), in north-west Wales is therefore a valuable resource for understanding the use of animal products during what was a formative period in the creation of Welsh identity. A rich artefact assemblage from the site demonstrates trade and cultural contacts across the Irish Sea region and beyond, and the zooarchaeological remains are well-placed to provide an additional insight into the contribution animals made to the wider economy.

This paper will present the findings from zooarchaeological analysis of over 20,000 recorded animal bone fragments from Llanbedrgoch. Using methods such as species abundance, biometry, mortality profiles and stable isotope analysis, it will explore how this evidence base adds to our knowledge of food systems and animal husbandry practices at the site.

3 REDATING VIKING AGE DUBLIN: THE MARINE RESERVOIR EFFECT IN DUBLIN’S FURNISHED BURIALS

Kinirons, Samuel (University College Dublin) - Leggett, Sam (The University of Edinburgh)

This paper presents the preliminary results of a project which is re-dating eight Viking Age burials excavated in Dublin between 2002 and 2005. When these burials were originally submitted for radiocarbon dating c.20 years ago, they returned surprisingly early dates. Some of these suggested that the burials predated the first historically attested Scandinavian overwintering in Dublin in 841 CE and contradicted the typological dating of the accompanying grave-goods. These early dates are therefore of great significance, in that they are key to our understanding of the beginnings of Viking Age Dublin.

In recent years several isotopic studies have demonstrated that early medieval Scandinavians often had a relatively high proportion of marine protein in their diets. This means that their radiocarbon dates were skewed by the marine reservoir effect, making them appear older than they actually are. Several burials have since been re-dated, most famously those at Repton. These examples have called these Dublin dates into question and precipitated the current project.

This project has therefore sought to conduct isotopic testing to establish proportions of marine dietary intake and to re-date these burials taking marine reservoir corrections into account. The work was undertaken in collaboration with Dr Sam Leggett’s ArchaeoFINS project which aims to trace the re-introduction of substantial fish consumption

across the Irish and North Seas during the early medieval period. The redating of these burials therefore exemplifies the potential of an international collaborative study with a dual focus on local specificity and broader trends. It promises to expand our knowledge of both local chronologies and wider shifts in marine resource exploitation across northwestern Europe.

4 **CELTIC CONNECTIONS: INVESTIGATING MOBILITY IN EARLY MEDIEVAL WALES USING MULTI-ISOTOPE ANALYSIS**

Faillace, Katie (Cardiff University) - O'Brien Butler, Ciara (Cardiff University) - Madgwick, Richard (Cardiff University)

This paper investigates regional mobility networks among early medieval Celtic-speaking communities using material from North Wales and South Wales as comparative case studies, and identifies avenues for future isotopic work in the wider "Celtic" west.

Presenting new and unpublished multi-isotope ($^{87}\text{Sr}/^{86}\text{Sr}$, $\delta^{18}\text{O}$, $\delta^{34}\text{S}$, $\delta^{13}\text{C}$, and $\delta^{15}\text{N}$.) data from four sites in North and South Wales representing c. 100 individuals, this study provides evidence for widespread migration throughout early medieval Wales, both within and beyond its borders. Dietary isotopes are examined in identifying intra-regional migrants, and the overall range of values obtained from these sites is considered against the variation found at contemporary sites. These findings particularly build upon the pioneering work by Hemer which demonstrated diverse origins for multiple individuals from South Wales, including the identification of likely migrants from beyond Britain. Taken together, the isotopic evidence from Wales demonstrates greater variability than predicted by current mapping, which presents a challenge when situating these communities within wider networks, with potential connections in Ireland, Scotland, Cornwall, and the Mediterranean. Interpretive issues are further compounded by methodological inconsistencies ($\delta^{18}\text{O}$), variable mapping in regions that are potential connections, and a paucity of supporting material and historical evidence. Despite the caveats imposed on the dataset, the isotopic data from Wales demonstrates connected nature of early medieval "Celtic" communities with the wider world.

5 **BIOLOGICAL DISTANCE ANALYSIS IN EARLY MEDIEVAL WALES: EXPLORING KINSHIP AND POST-MARITAL RESIDENCE**

O'Brien Butler, Ciara (Cardiff University) - Lane, Alan (Cardiff University) - Madgwick, Richard (Cardiff University)

This paper presents the results of intra-cemetery biological distance analysis of four skeletal assemblages from Wales dating to the early medieval period. This formative period of Welsh history was one of great socio-political change. Archaeological research has revealed significant regional and chronological complexity in power structures, settlement patterns, and mortuary practice throughout the period 400-1100 AD. Bioarchaeology has historically had a limited contribution to these debates, however, due to the poor survival of bone in the country. In recent decades the corpus of human remains from Wales has grown substantially, enabling osteological evidence to inform on wider themes within early medieval research, most notably in the areas of mobility and migration using isotope analysis.

Through biological distance analysis, this paper adds a new dimension to the growing field of bioarchaeology in Wales – that of genetic affinities within cemetery populations. Analysis of dental metric data was performed to reveal whether communities practised matrilineal or patrilineal residence patterns, and to investigate the influence of biological affinity on cemetery organisation. Analysis of kin-structured burial was supported by spatial statistics to verify the existence of grave groups which may represent family plots. Four cemetery case-studies, two from southeast Wales and two from Anglesey, were used. The results highlight the intricacy of kinship systems and the ways in which kinship identities were translated into the mortuary arena in early medieval Wales. Post-marital residence analysis of these sites also revealed regional and chronological variation in patterns of sex-based mobility, suggesting residence practices and gender relations in early medieval Wales were more complex than previously understood. The use of biological and spatial analysis of cemeteries contributes greatly to our understanding of these communities in a period of upheaval and social change.

6 **LIFE AND DEATH IN IRON AGE WALES: RESULTS FROM RADIOCARBON DATING, HISTOLOGICAL AND STABLE ISOTOPE ANALYSES FROM CASE-STUDY SITES**

Bricking, Adelle (Amgueddfa Cymru - Museum Wales) - Davis, Oliver (Cardiff University) - Madgwick, Richard (Cardiff University)

The study of human remains provides us with our most direct window onto the Iron Age population in Wales. However, burial evidence from Wales has been understudied compared to areas such as Yorkshire and Wiltshire. This is due in part to poor preservation as acidic soils destroy much of the osteological material—for example, Rowan Whimster (1981) identified only eight records of Iron Age burial in the whole country. This led to the popular assumption that the lack of human bone means that the majority of burial rites were "archaeologically invisible", particularly excarnation

within hillforts. However, a more recent reappraisal of the published and unpublished literature on excavations of Iron Age sites by Oliver Davis (2017) has shown that the corpus of burial material in Wales is much larger than previously recognised. This provides an opportunity to assess funerary rites and treatment of the dead, mortality profiles, health, diets and origins of the Iron Age population in Wales.

This paper presents the results of recent radiocarbon, histological and isotope analysis from two sites with the largest assemblages – RAF St Athan in the Vale of Glamorgan and Dinorben in Conwy. Through a multidisciplinary approach that integrates radiocarbon dating, histotaphonomic, and isotopic analyses with a contextual examination of the burial sites, this paper aims not only to refine our comprehension of mortuary behaviours but also to shed light on the broader aspects of life in the Iron Age, including dietary habits and population origins in Wales.

1094 **PERFORMATIVITY, NETWORKS AND AGENCY IN GEOMETRIC ICONOGRAPHY. TOWARDS AN AESTHETICS AND VISUAL LANGUAGE ARCHAEOLOGY**

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Moreno Padilla, María Isabel (Instituto Universitario de Investigación en Arqueología Ibérica. Universidad de Jaén (España)) - Prieto-Olavarría, Cristina Alejandra (Instituto Argentino de Nivología, Glaciología y Ciencias Ambientales (IANIGLA). CONICET, CCT Mendoza (Argentina); Universidad Nacional de Cuyo (Mendoza, Argentina))

Session format: Regular session

Geometric patterns have accompanied human societies for thousands of years, from the Middle Paleolithic in Europe to the hunter-gatherers of the Early Holocene in America. They were developed in cave paintings, ceramics, textiles, sculptures, architecture, body ornaments, domestic tools, weapons, jewelry, among other materials. These patterns are found in various contexts and are associated with a wide range of periods. This broad range shows a complex manifestation, posing theoretical and methodological challenges for archaeological research. While some attention has been given to iconographic and semiotic analysis in recent decades, and new approaches have been incorporated from cognitive archaeology or material agency theories, we believe that the theoretical and methodological development of Aesthetic and Visual Language Archaeology remains limited.

This session examines geometric aesthetics as a historical and social process that legitimizes, conditions, or demands social changes. In this context, geometric patterns played a crucial role in shaping socioeconomic and symbolic structures, and this iconography was fundamental for the construction and consolidation of cultural dynamics. The session aims to showcase works that analyze the agency, networks, and performativity of geometric iconography in Archaeology and Anthropology. To achieve this, we contend that geometric language is not merely a passive accessory or a mere ornament without meaning; rather, it actively shapes historical trajectories.

From a diachronic perspective, we aim to explore various theoretical and methodological approaches that enable the analysis of geometric language and, in some cases, its integration with figurative iconography. The core themes of the session encompass investigations into: 1) the ontological and epistemological perspectives in geometric iconography; 2) new methodologies; 3) variability of materials linked to geometric patterns; 4) analysis of symbols, schemes, codes, and narratives; 5) levels of performativity of geometric language; and 6) connectivity between geometric and figurative language.

ABSTRACTS

1 **DIAMOND-SHAPED LATTICE PATTERN IN NUBIA (EGYPT, SUDAN)**

Wozniak, Magdalena (University of Copenhagen)

The decorative repertoire of medieval Nubia was mainly explored through the study of ornamental patterns in medieval mural paintings (Martens-Czarnecka 1982), as well as from the ceramic perspective (Adams 1986). While these works provide detailed typologies, characterising chronological periods, they do not investigate further the importance and possible meaning of this specific ornament, nor they discuss its widespread use on many different media. For example, the diamond-shaped lattice appears notably on the edges of garments of both common people and the elite since the period of Meroe (300 BCE – 300 CE) until the late period of the kingdom of Makuria (13th-15th c. CE). The goal of this presentation is to give an overview of the presence of the diamond-shaped lattice on various media in Nubia in a long-durée perspective, with a focus on dress (clothing, accessories) and to consider the possible significance of this pattern, which could help to understand the permanence of this ornamental tradition.

2 AVICENNIAN NOETICS AND AVERROIST AESTHETICS IN MARINID GEOMETRY

Emparán Fernández, María Antonieta (Albert-Ludwigs-Universität Freiburg)

After the loss of what Ibn Khaldun calls 'aṣabiyya within the Marinid dynasty (mid-13th - 15th centuries), other symbolic elements were developed by the Marinid dynasty to legitimise itself in power. One of these strategies was the construction of madrasas (superior educational institutions), which had an ornamental programme based on a complex geometrical system, the zillij (geometric ceramic tilework). According to Ibn Khaldun's master, al-Abili, the Marinid madrasas were institutions for disseminating the official dynastic programme, and therefore, the ornamental programme should not be considered to be unconnected with it.

This contribution will present the social and intellectual interactions to be considered when analysing the zillij and the process of construction of the geometric patterns as visual proof. With these elements, it is hypothesised that the designers of these geometric patterns correspond to members of the intellectual elite of Fez, and the geometric designs of the zillij possess a symbolic language addressed to their peers, the students and teachers of the madrasas. Therefore, the zillij reflects both an Avicennian noetic and an Averroist aesthetic.

3 UNVEILING ICONOMETRIC CONVENTIONS: TALAMANA IN CENTRAL INDIAN ART

Sharma, Priya (Archaeology; Art - Architecture; culture; ancient indian history)

Art was created in prehistoric periods on little objects and the walls of caves, depicting themes such as religion and nature. Ancient Indian art was created by fusing larger folklore with regional beliefs. This combination gave rise to intellectual art texts such as the Shilpa-Shastra. In the twelfth century, Vedic religious concepts coexisted with indigenous art in central India.

This essay discusses Talamana, an ancient measurement and proportion system of art in the creation of temple sculptures. It demonstrates how local beliefs persisted in the face of widespread religious notions. This study uses ancient Central Indian art to examine how major religious movements influenced regional thinking. Central Indian region in the context of this article covers almost 4,43,439 Square kilometres namely Chattishgarh, Madhya Pradesh, and Maharashtra.

The study allows us to understand how many forms of art coexisted in ancient India by examining both words and images. It also discusses the state of society at the time and asserts that diverse viewpoints could coexist peacefully even then. This is a quantitative research methodology involving textual analysis of existing literature along with new archaeological explorations. Prior context works were focused predominantly on representing traditional art literature. An equal number of works were also produced on architecture. An incorporated work of the two along with the regards of native tradition is yet to be done.

Sometimes, indigenous beliefs are incorporated into larger ones to make them seem less significant. This happens in three ways: First, smaller cultures may disappear as larger global beliefs become more dominant. Second, they may merge with larger beliefs to ensure their survival, not necessarily under pressure but out of necessity. Third, all beliefs can coexist, even if they differ or aren't well-documented historically, as seen in society today.

4 PRAEHISTORIC TEXTILES - MORE THAN JUST APPEARANCES AND HAPTIC

Banck-Burgess, Johanna (ComTex)

Ornamental elements, such as geometric patterns, are compared with each other in archaeological research on different object carriers. Often regardless of whether they are visible on everyday tools or sacred items, objects of different materials or functions, like ceramics or weapons. Research on prehistoric textiles has shown that the visual perception of textiles is significantly supplemented by another essential factor. A factor that is completely beyond visual perception. In prehistoric times, textiles are not exclusively decorative. Patterns are incorporated during the manufacturing process. Supplemented by details in the production process that are culture-specific and hidden from the eye of the beholder, i.e. not visible to the naked eye. Subsequent decoration, such as embroidery, in which the textile is a pure decorative medium, did not exist in the textile production in prehistoric Central Europe. What conclusions can be drawn from this? Is it even possible to interpret patterns in isolation from the carrier medium? This article provides textile archaeological background knowledge on this topic as a basis for discussion.

5 GIVING SHAPES TO PLANTS. THE ABSTRACTION OF PLANT MOTIFS IN IBERIAN PAINTED POTTERY (3RD-1ST CENTS. BCE)

Harding, Pablo (Universidad Autónoma de Madrid) - Uroz-Rodríguez, Hector (Universidad de Murcia)

This paper analyses the phenomenon of the abstraction of plant motifs into geometric as evidenced in Iberian figurative ceramic iconography from the south-east and east of the Iberian Peninsula (3rd-1st centuries BC). The case study chosen is the four-petalled flower, which appears most explicitly in Illicitan style pottery, whose regional variants

reveal a generalised tendency towards schematisation which, at its most extreme, reduces the flower to purely geometric forms: four-pointed 'X' shapes and 'double axe' motifs consisting of two triangles facing each other.

The recent re-evaluation of the role of geometric decoration has highlighted the nature of the fine line dividing plant and geometric motifs, a point noted but left unexplored for decades. This difficult distinction, which obeys the complex dynamics of abstraction and schematization, has recently been explored for motifs such as "stars/asterisks" and "S" shapes, which straddle both categories.

The four-petalled flowers can be linked to the symbolic sphere of the female divinity, on whose body they appear on a ceramic vessel from La Alcudia and a plastic vessel from Libisosa. The locations chosen for the placement of these motifs are repeated regardless of their level of abstraction: below the handles or in the centre of plant compositions. Also, geometric variants are not the result of a linear evolution: they appear, to a large extent, during the same period. There is evidence of regional preferences: a widespread trend towards diversity and schematization, with plant-based variants being more frequent in the southeast.

This paper argues that the abstraction of plant motifs into geometric shapes can be traced back to the very beginning of figurative ceramic iconography and reveals the capacity for semantic and conceptual synthesis of Iberian painters, who worked on behalf of the Iberian elites.

6 MORE THAN JUST CONCENTRIC CIRCLES. PERFORMATIVITY AND AGENCY IN IBERIAN POTTERY OF THE UPPER GUADALQUIVIR (SPAIN)

Moreno Padilla, María Isabel (Instituto Universitario de Investigación en Arqueología Ibérica. Universidad de Jaén)

Can geometric decoration on potteries communicate ideological messages and contribute to legitimizing and reinforcing social changes? Is geometric language a reflection of social and cultural identities? Was it play an active role in times of crisis and change, especially those linked to conflict? Is there a geometric code that can be analyzed, characterized, and contribute to the understanding of Iberian societies?

This work asserts the importance of a phenomenon barely addressed in the archaeological research of Iberian societies in the western Mediterranean during the Iron Age: decoration, language, and, by extension, geometric styles. Specifically, this proposal emphasizes the analysis of potteries decorations developed between the late 3rd century BC and the 1st century AD, in a period defined by the Second Punic War and its impact on the territory.

The analysis of different contexts, such as Ilturgi (Mengíbar, Jaén), Castulo (Linares, Jaén), Castellones de Céal (Hinojares, Jaén), or Tutugi (Galera, Granada), highlights the role of these decorations in the mechanisms of socialization and identity reconfiguration that take place after the conflict. In this period, characterized by the dismantling of Iberian geopolitical structures and Roman territorial control, the performativity of geometric iconography reaches its peak: the pattern of regularity and stylistic changes detected in geometric production during this period reflect the new dynamics of aestheticization of these societies. At the same time, they serve as a means of social, cultural, and identity resilience.

7 SYMBOLIC GRAPHIC CODES AND THEIR ROLE IN THE COMMUNICATIVE PROCESS IN THE SOUTHERNMOST PART OF THE WORLD (PATAGONIA, CHILE)

Muñoz-Soto, Camila (Université Paris 1 Panthéon-Sorbonne, ED112, UMR 8068 TEMPS; Universidad de Castilla-La Mancha, Fac. de Ciencias de la Educación y Humanidades)

The rock art of the continental sector of the southernmost part of Patagonia, Chile, has often been a materiality left behind in the study of the social and cultural dynamics of the hunter-gatherer groups that settled in this vast region, on the contrary to the recording of more traditional materialities. This is why its study has been constantly relegated to the characterization and identification of styles which, nevertheless, have allowed us to determine that we are dealing with a graphic expression that is above all non-figurative, in which representations based on lines and dots predominate.

In the present work, the aim is to leave this notion aside in order to understand these elements as symbolic graphic codes, whose construction is not only based on the morphology of the motif. A geometric code analysis methodology is used, which considers the symmetry, colour and technique of the motif, and its position within the panel. In addition, the sites where pictographs were carried out and their possible relationship with other figurative codes are analysed. In this way, we intend to get an insight into the communication dynamics developed by the different groups settled across different areas of the continental territory of the extreme south of Patagonia during the last 3,200 years cal BP.

8 THE LINE IS ALIVE. ANDEAN ONTOLOGICAL PERSPECTIVES ON THE GEOMETRICAL ICONOGRAPHY OF TIWANAKU KERU VESSELS (500-1100 CE)

Villanueva Criales, Juan (Universidad Mayor de San Andrés)

Due to its figurative iconography, the Tiwanaku society has traditionally been understood as exceptional within the Bolivian Andes. The keru vessel, the most emblematic ceramic of Tiwanaku, was perceived as a kind of diffuser of its influence on regions and populations possessing simple geometric motifs, allowing for civilizational and imperial narratives. Given that the post-Tiwanaku style is also geometric, ruptures were posited between the indigenous past and present, narratives always functional to neocolonialist and nationalist projects.

This work starts from the opposite extreme by recognizing, from the beginning, that Tiwanaku imagery is predominantly geometric and incorporates an Andean theoretical-ontological framework. First, keru vessels today are not considered objects to mediate the interaction between humans and other beings but rather subjects that participate in those interactions. Although the Andean world is made of living materials, manipulating these materials involves turning them into people (jaqichayaña, as Arnold documents) with defined characteristics. The Tiwanaku repertoire includes ceramics with human or animal shapes, thus, living bodies in the same way Alberti proposes for ceramics from northern Argentina. On the other hand, giving personality to a hyperboloid vessel could require something similar to what Lagrou documents among the Cashinama: animating the body through the dynamism of geometric graphics, involving the viewer's gaze in the movement, from which the figures emerge only as a consequence.

The analysis of kerus from several European and Bolivian museums allows us to argue that their painted geometry segments horizontal spaces in various ways, creating circular movements that give life and character to the ceramics. Although animal and human images can emerge from this geometry, this is not always necessary: the geometry is alive. In this light, Tiwanaku fits more easily into the worlds of indigenous creation of yesterday and today.

9 AMERINDIAN SHAMANIC PERSPECTIVISM AND DIAGUITA VISUAL ART: CONTRIBUTION OF SYMMETRY IN INDIGENOUS IDENTITIES CONSTRUCTION

González Carvajal, Paola (El Olivar Foundation)

Chilean Diaguita culture developed in the semi-arid north of the country, between years 1,000 to 1,536 AD, and stands out for a complex abstract and symmetrical visual art development (González 2013). Diaguita art is linked to a long tradition of South American Shamanic Art (González 2016); this tradition is still present in current Amazonian indigenous peoples such as Shiiipibo-Conibo and Cashinahua, among others. The Diaguita culture belonging to this tradition is suggested by contextual aspects, such as the practice of hallucinogen consumption, and the association of its art with an animal alter ego (jaguar), as well as by the existence of intrinsic characteristics of its visual art. The use of complex symmetries stands out in them; endless variability, gradual complexity, hypnotic attraction, among others. Also highlights the kinetic properties of his visual art, which produce movement or vibration illusion on the designs, and the possibility of visualizing them in positive/negative, producing an interplay between figure and background (González 2013:76). Els Lagrou (2012) studies visual techniques used in symmetrical art of the Amazonian Cashinahua, intended to produce optical games in their designs; the author links these graphic techniques with Amerindian perspectivism, and a conception of the animist world (sensu Viveiros de Castro 2018). This ontology is characterized by the idea of transformability of forms and bodies.

On the other hand, the excavation of living and funerary areas on Diaguita site El Olivar (Cantarutti and González 2021; González 2023), allowed to contextualize Diaguita art, and characterize the mortuary practices of a specific community for four centuries. Relationships between artifacts, camelids and humans, suggest the existence of an ontology related to Amerindian shamanic perspectivism, also visible in their visual art.

10 GEOMETRIC DESIGNS OF VILUCO CERAMICS. APPROACH FROM ARCHAEOLOGY AND INDIGENOUS KNOWLEDGE (MENDOZA, ARGENTINA)

Prieto-Olavarría, Cristina (IANIGLA, CONICET) - Herrera, Liliana (Comunidad Huarpe Guaytamari; Organización de Naciones y Pueblos Indígenas en Argentina) - Candito Herrera, Cintia (Comunidad Huarpe Guaytamari)

This work arises from the need to establish an intercultural dialogue around the interpretation of the geometric designs of Viluco ceramics (Mendoza, Argentina). Three women who work and/or live in the high mountains of Mendoza (Argentina), intertwine our knowledge to generate a shared story about a set of archaeological vessels that were produced approximately 500 years ago, but continue to mean in the present. We rely on the knowledge generated by archaeological studies, especially on Andean visual languages, and the knowledge of the Huarpe community acquired through oral tradition and practical knowledge. The latter is part of the narratives that this native people transmit not only within their own community, but also to the rest of the national and foreign people (at educational and cultural centers, in lectures and conferences).

This research makes visible the knowledge of the native communities that have been silenced by the official voices (science, museums) and helps to build a notion of heritage, tangible and intangible, which functions as a means for transformation and social innovation.

11 SYMMETRIES OF CULTURE

Washburn, Dorothy (Oberlin College; University of Pennsylvania)

This paper introduces scholars at EAA to an annotated bibliography of studies in English that explore how the property and concept of symmetry appears in different domains of culture. Here I present a sampling of these studies, focusing on how symmetry is manifest in plane pattern geometry classes on many kinds of materials—ceramics, textiles, tile, wood, brick, metal, etc.. This approach has not only enabled systematic description of the organization and generation of decorative patterns, but also has disclosed how pattern symmetries are structural metaphors of the same symmetries in other domains of culture. Within a given culture there are preferred symmetrical ways to structure activities from fundamental cosmic principals, to kinship networks, to village layouts. I describe studies that illustrate how the continuities and changes in pattern symmetries correlate with continuities and changes in activities in the social, economic and political domains as well as with environmental factors. The bibliography will be published in the journal *Symmetry: Culture and Science*. An annotated bibliography that describes work in the Americas in Spanish and Portuguese is being collated by Diego Jorge Gallardo, Jujuy University, Argentina, and will appear in a future issue of the journal.

1095 SCALE MATTERS. THE COMPLEXITY OF RECONSTRUCTING PAST HUMAN-ENVIRONMENT INTERACTIONS

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Walker-Friedrichs, Fiona (Kiel University) - Vandam, Ralf (Vrije Universiteit Brussel) - Willett, Patrick (Vrije Universiteit Brussel)

Session format: Discussion session (with formal abstracts)

This session delves into the dynamic interplay between different scales of analysis and the spatial diversity of human-environment relationships throughout history. Environmental archaeology prioritizes understanding these relationships, offering insights for contemporary dialogues on sustainability, resilience, and the delicate equilibrium between humans and their surroundings. Recognition of scalar and contextual specificity works to avoid imposing universalized assumptions in our interpretive frameworks about how environments were used by past peoples. When universal explanatory frameworks are uncritically applied to discrete regional contexts, they often work to obscure our comparative understanding of human-environmental relationships.

Recent years have witnessed a surge in studies focused on ever-increasing 'big-data' analyses. However, this growth brings with it a discernible challenge – a widening gap between the abundance of data and the interpretations that can be drawn from them. The datasets crucial for reconstructing human-environmental interactions clearly vary in resolution, accuracy, and sampling intensity, presenting an obstacle to straightforward syntheses.

In this session, through the presentation of diverse case studies at various scales, we aim to unravel the nuanced challenges posed by these divergent datasets through the presentation of diverse case studies at various scales and analytical frameworks. By scrutinizing the intricacies within our empirical approaches, we hope to not only illuminate the past but also pave the way for more robust methodologies and interpretations in the future.

ABSTRACTS

1 WHY SCALE MATTERS

Walker-Friedrichs, Fiona (ROOTS- CLuster of Excellence, Kiel University)

The session's introduction underscores the importance of adapting research methods and inquiries according to the scale of our studies. Despite the prevalence of "big data," it's essential to recognize that data collected over larger areas differ significantly, necessitating distinct approaches compared to smaller-scale studies. Interpretations applicable to one site may not be transferable to a site just several kilometres away, and the nuances between sites are often overlooked when combining larger datasets. This challenge is further compounded by variations in the resolution, accuracy, and sampling intensity of datasets crucial for reconstructing human-environmental interactions, posing a significant obstacle to straightforward syntheses.

This issue can be effectively illustrated by plant stable isotope data. Plant stable isotope data (for example $\delta^{13}\text{C}$ or $\delta^{15}\text{N}$) exhibits a strong regional dependence and significant natural variability even at the local level. Consequently,

questions arise regarding whether long-term studies over a large area reveal overarching trends or instead unveil divergent regional trends.

2 RECONSTRUCTING PLANT FOOD ECONOMY AT A FUNNEL BEAKER VILLAGE: HANDLING ABUNDANT DATA FROM A SMALL SITE

Krubeck, Sara (Kiel University)

On a small island in a former fjord in the Western Baltic area lies the site Oldenburg LA77, Schleswig-Holstein. It stands out as the best archaeobotanically investigated Neolithic site in northern Germany, providing a sound data base for further investigations. The preserved settlement remains, dating to 3270-2920 cal BCE (Middle Neolithic) are a regional expression of the Funnel Beaker Complex. The features were extensively excavated and systematically sampled for botanical macro-remains, thus enabling an uncommonly broad and detailed statistical evaluation of plant-use and distribution at the site, structured not only spatially by context attribution, feature type and terrestrial vs. wetland area, but also temporally over the three archaeologically distinguished settlement phases. Crops dominate the botanical inventory and yield a strong basis for plant food economy reconstructions. A temporal trend of favouring emmer over barley becomes visible. Significant deviations in the ratios of grains vs. threshing remains and weedy species as well as in the frequencies of the main cereal types emmer and barley can be found in the comparison of house contexts, well features and the settlement margins at the shore zone, permitting a reconstruction of the spatial pattern of economic activities, i.e. food production, involving plants. The identified pattern furthermore implies social aspects of task specialization and communal strategizing. Gathered wild plants like fruits, nuts, herbs and others are included in the quantitative analyses and discussed in terms of their role within the agriculturalist subsistence strategy.

3 EXPLORING THE POTENTIAL OF WELL-LIKE FEATURES AS A SOURCE OF ENVIRONMENTAL ARCHAEOLOGICAL INFORMATION. CASE STUDY FROM SOUTHERN BULGARIA

Katreva, Yoanna (Faculty of History, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria; Division of Palaeobotany and Palynology, Institute of Biodiversity & Ecosystem Research, Bulgarian Academy of Sciences, Sofia, BULGARIA) - Marinova, Elena (Laboratory for Archaeobotany, State Office for Cultural Heritage Baden-Württemberg, Gaienhofen-Hemmenhofen, Germany) - Andonova-Katsarski, Mila (Division of Palaeobotany and Palynology, Institute of Biodiversity & Ecosystem Research, Bulgarian Academy of Sciences, Sofia, Bulgaria) - Boyadzhiev, Kamen (Exhibitions department, National Archaeological Institute with Museum, Bulgarian Academy of Sciences, Sofia, Bulgaria) - Boyadzhiev, Yavor (National Archaeological Institute with Museum at the Bulgarian Academy of Sciences, Sofia, Bulgaria) - Bozhinova, Elena (Regional Archaeological Museum – Plovdiv, Bulgaria) - Zidarov, Petar (Freelance archaeologist) - Petrov, Valeri (Institute of Ethnology and Folklore Studies with Ethnographic Museum, Bulgarian Academy of Sciences, Sofia, Bulgaria)

This study aims at exploring the potential and limitations of plant micro- and macrofossils preserved in two deep negative features for reconstructing the past natural and anthropogenic environment. The study sites, the Chalcolithic tell of Yunatsite and the multiphase flat settlement site near Skutare are located in Southern Bulgaria. Both features were dug into such a depth that they reach the current groundwater table. This opens up the discussion whether they served the specific function of wells within the two settlements. The reduced oxygen conditions lead to good preservation of plant remains accidentally or intentionally found in the backfill of the features. In order to study these deposits, sediment samples and sediment cores were collected from tell Yunatsite. The results suggest the use of coniferous wood (high concentrations of fir, *Abies* sp.) as a construction material, also recorded amongst the macro-botanical remains and show a notably open landscape with predominantly non-arboreal pollen (NAP) with strong presence of palynological anthropogenic indicators. A profile-sampling technique was applied to an EBA feature from Skutare, where twenty-five samples were extracted representing the various stages of the gradual filling. The pollen concentration is rather low and variable taxon diversity is lacking. The grass and herbs pollen are dominated by the grass family (Poaceae), the Daisy family (Asteraceae), the Goosefoot (Chenopodiaceae) and Chicory (Chicoriaceae) subfamilies. The arboreal pollen (AP) group presented oak (*Quercus* sp.) and alder (*Alnus* sp.). The above palynological data also correspond to the macro-botanical samples, where cereal cultivars (mainly barley, *Hordeum vulgare*) were amongst the archaeobotanical remains, while oak charcoal dominates the anthracological assemblage. As a whole, the sampling strategy proved to be efficient to obtain detailed and diverse environmental evidence, while the results – promising for reconstructing the anthropogenic environment adjacent to both sites.

4 ON UNINTUITIVITY OF SCALE: THE EMERGENCE OF GROUP AGENCIES THROUGH SPATIAL INTERACTIONS IN SOCIAL-ECOLOGICAL SYSTEMS

Sikk, Kaarel (University of Tartu)

The complex systems approach, particularly agent-based models (ABM), has been extensively used in studying settlement systems for over two decades. ABMs, centred around the concept of agency in decision-making and actions,

have seen diverse applications. Urban systems have often been modelled with cities as agents, interacting through urban flows, while archaeological studies have focused on smaller units like villages or households to investigate both contemporary urban phenomena and the historical formation of settlement patterns. This variability in the choice of agency level reflects the social complexity of the studied systems or the empirical data available. Yet, the integration of these levels and their collective impact on settlement forms poses an ongoing question.

This research explores a theoretical ABM of settlement system formation from a social-ecological systems perspective, built on the micro-actions of individuals making residential choices within a spatially explicit landscape. These decisions, influenced by local environmental conditions and the spatial relation to other agents (social context), propel changes in spatial structures, leading to a dynamic complex system characterised by information flows and feedback loops. An exploration of the model across its full parameter range, including sensitivity to spatial configuration and the stochastic nature of individual choices, reveals the generative power of spatial interactions. These interactions lead to the emergence of group agencies, distinct from the behaviours of individual agents and formed solely through the spatial interplay and environmental interactions, challenging the direct application of individual-based concepts like affordances or environmental determinism to system-wide patterns. Linking different levels of decision-making agencies requires understanding the complexities separating them.

5 UNRAVELING THE COMPLEXITY OF HUMAN-ENVIRONMENTAL DYNAMICS IN THE WESTERN TAURUS MOUNTAINS. INSIGHTS FROM INTERDISCIPLINARY RESEARCH AT SAGALASSOS

Vandam, Ralf (Vrije Universiteit Brussel) - Willett, Patrick (Vrije Universiteit Brussel) - Şenkul, Çetin (Süleyman Demirel Üniversitesi)

Three decades of interdisciplinary research from the Sagalassos Archaeological Research Project (KU Leuven) have provided extensive amounts of archaeological and environmental datasets for the Western Taurus Mountains in SW Turkey. The picture emerging as a result of this research is very complex and heterogeneous from both archaeological and environmental perspectives. The wide disparities in local hydrology, topography, and geomorphology within the Sagalassos study area interact to create conditions for a patchwork of vegetative cover and soil conditions – which, alongside political, social and economic factors, must also have impacted human activity. In this paper, we give a detailed overview of our new human-environmental research endeavors by presenting the first new results and outlining ongoing and future efforts. First, we have taken new pollen cores (including ITRAX analysis) to gain a better insight into past vegetation changes. Second, we are studying the relationship between modern pollen records and modern vegetation to help convert fossil pollen records into more accurate quantitative vegetation reconstructions. Third, we are aiming to collect high-resolution paleoclimate data, i.e. stable isotope analysis of lake sediments (Burdur and Gölcük Lakes) and cave stalagmites (Insuyu Cave). Lastly, we are continuing our archaeological survey research to expand the area and chronological range of comparability with the environmental data.

6 A TALE OF TWO CHESTNUTS: MODELLING THE ECOLOGICAL NICHE OF *CASTANEA CRENATA* AND *AESCULUS TURBINATA* DURING THE JOMON PERIOD

Brainerd, Leah (University of Cambridge) - Crema, Enrico (University of Cambridge)

The Jomon period (16,000–2,800 cal BP) of prehistoric Japan was characterised by a subsistence economy that poorly fit with traditional categories such as 'hunter-gatherers' or 'neolithic' due to the extensive use, management, and in some cases, possible domestication of a range of plant resources. In particular, the exploitation of several arboreal species, namely *Castanea crenata* (chestnut), *Toxicodendron vernicifluum* (lacquer tree) and, at a later date, *Aesculus turbinata* (horse chestnut), has led some to coin terms such as 'arboreal neolithic' (Imamura 1999). Chestnut and lacquer trees have evidence for management from the Early Jomon, but from the Middle (ca 5,500 - 4,500 cal BP) to the Late Jomon (ca 4,500 - 3,300 cal BP), fossil records indicate a shift, with horse chestnut becoming equal to or surplanted chestnut as the dominant wild nut species consumed across Eastern Japan. Concurrent with these changes, we observe increased levels of social stratification and major demographic fluctuations across the archipelago. The shift from chestnut to horse chestnut in Eastern Japan has been traditionally attributed to the 4.2-kiloyear cooling event, yet no formal assessment has been made to determine where and whether this climatic deterioration impacted the ecology of *Castanea crenata* making its exploitation less sustainable and promoting the consumption of the more labour-intensive *Aesculus turbinata*. This paper will explore the relation between the occurrence of *Castanea crenata* and *Aesculus turbinata* during the Middle to Final Jomon period by examining the physiological requirements of both plants and modelling them via ecological niche modelling. When examined in conjunction with the spatial distribution of archaeological sites during this period, these models will provide insight into where and whether these subsistence shifts were determined by environmental constraints during the latter half of the Jomon period.

1097 THE MINDREADING OF MATERIALITIES. ARCHAEOLOGY OF MOVEMENT AND SIGHT

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Silva Gago, María (INCIPIT-CSIC) - Vindrola-Padros, Bruno (Kiel University) - Verdonkschot, Jadranka (INCIPIT-CSIC) - Santos-Estévez, Manuel (INCIPIT-CSIC) - Zaghi, Regina (INCIPIT-CSIC)

Session format: Regular session

Interpreting the archaeological record, archaeologists make a painstaking effort to read the material's mind. However, novel neuroscientific methods formally support the role of the material world as an active element in our cognition too.

This session aims to discuss how thought is shaped by archaeological materialities, addressing locomotion in proposals of cognitive archaeology.

This topic is comprised of the study of the gaze (ocular movements), general bodily movement and navigation, but also the directed motion and techniques of the body in creation (e.g. pottery making) or expression (e.g. dancing).

This includes tracing depictions and traces of bodily expression in the archaeological record, but also an attempt to break the fourth wall in the study of modern participants' (visual and motive) interactions with archaeological remains or material processes. By studying the way that movement, behaviour and gaze are conditioned by materialities and the pertaining processes, it is aimed to deduce meaning in terms of cognitive and interpretational patterns.

Methods currently available to trace people's thoughts and actions in different relations to material culture are addressed. We are also interested in discussing new approaches in experimental design, data analysis and modelling, highlighting for example the use of eye-tracking, other trackings of bodily movement or Transcranial magnetic stimulation (TMS) and Electroencephalography (EEG) methods as techniques for exploring past cognition based on human – materiality relationships. Central to the contribution of these (neuro)scientific methodologies is a theoretical spine, as valuable archaeological narratives can be constructed only if scientific methods converge with a solid framework of thought.

We combine different narratives in interpreting archaeological depictions, tracing movement in the archaeological record, but also practising an enactive and cognitive approach of the senses in archaeology. Not only a joining of methodologies is discussed here, but also the transcending of ontologies.

ABSTRACTS

1 WAYS OF SEEING, WAYS OF WALKING. ROCK ART SITES AS A SOCIAL DEVICE

Santos-Estévez, Manuel (INCIPIT-CSIC) - Silva-Gago, María (INCIPIT-CSIC) - Zaghi-Lara, Regina (INCIPIT-CSIC)

In previous experiences, we have observed that viewers' behavior changes depending on the chronology of the panel. For example, in Alpine and Atlantic rock art for carvings dated in the Neolithic, observers could place themselves around the panel, and none of them would have a privileged viewpoint. However, in the Bronze and Iron Ages, the group of observers should be placed in front of the panel, and therefore they would have more restrictions to their movement surrounding rock, this would mean that there were fewer viewpoints to observe the panel, and the proximity to the rock would vary amongst observers.

This research uses movement-tracking techniques to take a more systematic approach to this question. Here we present the results obtained in two rock art sites, one dated in Neolithic and the other in Iron Age, both belonging to Atlantic rock art. The Neolithic one is located in a prominent outcrop, with many irregular surfaces, where the predominant designs are geometric, carved in horizontal and convex surfaces. The other site is located at the bottom of a valley, on almost vertical surfaces; in this case, the most frequent motifs are quadrupeds. This study pretends to analyse in what way the physical conditions of these sites, the shape of the panels, the structure of the compositions, and the iconography constrain the navigation through the panel. We aim to find the relationship between chronology, the movement of the observers and the way of seeing rock art.

This study is part of the project "XSCAPE: Material Minds". The general question of the project is to understand the interactions between the mind, objects, and the world. In line with this question, we analyze in what way rock art sites condition human movement, body posture, and its possible relation to the social structure of each period.

2 DANCING THE GAZE: REPERTOIRE FOR IMAGINING PREHISPANIC DANCES IN COLOMBIA

Posada, Carolina (Antioquia University)

Dancing the Gaze: Repertoire for imagining prehispanic dances in Colombia is a doctoral research in Arts at the University of Antioquia. Its main objective is to contribute to the historiography of dance in the country, as current

studies primarily focus on the colonial and 20th-century periods. The research emerges from the interest in exploring native dances, seeking their traces between the years 10,000 BCE and 1492 CE. Dance, although ephemeral, leaves graphic traces, bodily memories, and oral narratives, prompting the search for its imprints.

During the exploration of various museums in the country, over 100 images have been found in pieces of goldsmithing, pottery, petroglyphs, and pictographs that suggest the existence of dance performances related to rituals. To comprehend and engage with these images, the icon+choreo+graphy approach has been developed. This method combines iconographic appreciation, choreological studies, and an understanding of the ritual context, linking them with vital concepts from "indigenous philosophers" in Latin America and Mesoamerica. The aim is to approach the images from the cosmogonies specific to the territory and anchor the dance gesture in its relationship with elements such as space, time, movement, sound, and the paraphernalia necessary for transformation or becoming.

Beyond being mere material objects evidencing the past, these images represent a present that harbors the very essence of dance. In this context, the communication focuses on morfokinemas as indicated by Kaepler, akin to the minimal units of meaning mentioned by Cusicanqui. The purpose is to appreciate the gesture in its minute details, emphasizing its maximum symbolic value.

3 RETHINKING HUMAN BEHAVIOUR. AN EXPERIMENTAL STUDY ON THE VISUAL EXPLORATION OF CERAMICS

Silva Gago, María (Instituto de Ciencias del Patrimonio (INCIPIT-CSIC)) - Valiño-Perez, Arturo (Instituto de Ciencias del Patrimonio (INCIPIT-CSIC)) - Lima-Olivera, Elena (Instituto de Ciencias del Patrimonio (INCIPIT-CSIC)) - Fernandez-Pestonit, Alba (Instituto de Ciencias del Patrimonio (INCIPIT-CSIC)) - Martinez-Otero, Luis (Instituto de Neurociencias (Instituto de Neurociencias CSIC-UMH)) - Criado-Boado, Felipe (Instituto de Ciencias del Patrimonio (INCIPIT-CSIC))

Vision is a key source of sensory information in humans. The relationship between individual and environment is driven by vision, but it is essential to selectively focus attention on selected stimuli due to the huge amount of information from the surroundings. The patterns of visual attention can be studied through eye-tracking technology, which consists of measuring eye position and movements. Considering the relevance of visual perception in the human genus and embodied theories of cognition, this technology can provide a useful approach to understanding human behaviour from an evolutionary perspective. Visual behaviour has been analysed before related to different kinds of archaeological remains, from stone tools to rock art, showing divergences between objects from different chronologies. In the current study, we present the preliminary results of the analysis of prehistoric ceramics from several periods and sites, which show that visual behaviour varies according to chronology. As time and cultures evolve, visual exploration became higher and more vertical. These differences can reveal behavioural patterns associated to this materiality.

4 BREAKAGE AND UNCERTAINTY: HOW POTTERS LEARN FROM UNPREDICTABLE PHENOMENA

Vindrola-Padrós, Bruno (XSCAPE Project on "Material Minds" (ERC 2020 Synergy Grant 951631); Institute of Pre- and Protohistoric Archaeology, Kiel University) - Scholtus, Lizzie (XSCAPE Project on "Material Minds" (ERC 2020 Synergy Grant 951631); Institute of Pre- and Protohistoric Archaeology, Kiel University)

Given the ubiquity of ceramic materials in human history, a large part of archaeological research today is invested with understanding how people learn about pottery craftwork in a social environment and the material consequences of this process. A crucial, yet often unrecognised, part of pottery making is knowing about the different instances where breakage can occur and how to respond to these phenomena, which has been articulated elsewhere as part of a theory of breakage (Vindrola-Padrós, 2023). Continuing this line of argumentation, this paper aimed to systematically analyse the way in which potters learn from breakage phenomena and identify the cognitive effects of this process. Our hypothesis was that the knowledge about how wheel-thrown pottery breaks during manufacture becomes structured through repeated exposure to contingent breakage situations, such that with growing experience this knowledge becomes part of the subject's generative model of the object. To corroborate this hypothesis, a cross-sectional study on over 40 participants with different levels of expertise of wheel-thrown pottery was performed. Participants were asked to perform a series of tasks including drawing, free-viewing and task-driven viewing typical pottery fracture patterns with eye-tracking equipment, and responding structured questions about their background knowledge of the craft. Through these mixed methods, clear distinctions could be made between the cognitive response of experts and non-experts.

EXPLORING THE NEURAL PLASTICITY OF EARLY POTTERS: A MULTIDISCIPLINARY INVESTIGATION

Forte, Vanessa (Department of Science of Antiquities, Sapienza University of Rome) - Sartori, Luisa (Department of General Psychology, University of Padua) - Visalli, Antonino (IRCCS San Camillo Hospital, Venice) - Yildirim, Mustafa (Department of Cognitive Psychology, Ruhr University Bochum) - Galati, Gaspare (Department of Psychology, Sapienza University of Rome) - Vidale, Massimo (Department of Cultural Heritage: Archaeology, History of Art, Cinema and Music, University of Padua) - Faresin, Emanuela (Department of Cultural Heritage: Archaeology, History of Art, Cinema and Music, University of Padua) - Vallesi, Antonino (Department of Neuroscience, University of Padua)

This contribution presents the preliminary results of a study exploring the neural plasticity of early potters, combining experimental archaeology, cognitive neuroscience, and behavioural techniques. The development and transformation of ceramic technology during the Neolithic marked a profound shift, on the one hand, in the economy, social dynamics, and cultural practices, and, on the other hand, it likely demanded new cognitive and motor skills necessary to manage the constraints of a new raw material, such as clay. Drawing on cognitive approaches and the integration of archaeological methods with neuroscience techniques, our research explores the neuro-cultural mechanisms underlying ancient craft behaviours. Through a pilot study involving intensive training in Neolithic pottery-making techniques, participants' neural and behavioural changes were measured alongside their material production. Employing TMS-EEG co-registration, we examined neural indices, and analysed shape variations in handicrafts longitudinally, before and after training.

Our findings suggest changes in the primary motor cortex and enhanced symmetry and consistency in vessel and coil productions after intensive pottery training. This multidisciplinary approach contributes to shed light on mechanisms of material culture variation and human cognition and is promising for understanding technological evolution and its impact on past societies across different historical periods.

1101 IMPRINTS - TRACING LATE PREHISTORIC ENVIRONMENTAL IMPACT IN SOUTHERN EUROPE THROUGH NON/LOW INVASIVE METHODS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Vinci, Giacomo (University Of Padova) - Brandolini, Filippo (University of Newcastle) - Zeviani, Camilla (University of Cambridge) - Stoddart, Simon (University of Cambridge)

Session format: Regular session

At a global scale, human-induced modifications on the environment appear to have been widespread from around 1000 BCE. However, especially in the Mediterranean, the environmental impact of late prehistoric societies has long been underestimated.

Forest clearance, agricultural practices and grazing carried out in Southern Europe in the 2nd and 1st millennium BC had unprecedented and widespread effects on the long-term environmental dynamics, deeply modifying the vegetation cover, soils, and natural landforms. Prehistoric monuments, sometimes strongly degraded through millennia, are often a tangible product of these widespread anthropogenic activities. Overall, evidence of massive impact on the ecosystems is documented before Roman times by a growing number of studies.

In the last years, several non or low invasive methods (e.g. GIS-modelling, remote sensing, surveys, corings, geophysics) combined with a wide range of analyses (e.g. radiocarbon, pollen, OSL, micromorphology, seda-DNA) have been increasingly used to trace the environmental impact on these landscapes. In many cases, these methods are affordable and suitable to produce high resolution and comparable data.

To what extent and in which regions is it possible to detect major imprints of late prehistoric communities? Is it possible to track down unsustainable practices (e.g. replacement of species, extensive agriculture, fire activity?) that have consequences on landscape and settlement changes at specific regions?

By delving into the environmental impact of late prehistoric societies, we not only enrich our understanding of the past, but also acquire valuable insights that can guide current environmental management and policy. Ultimately, this contributes to a more ecologically responsible and sustainable future.

We aim to address these questions and issues by adopting a multi-proxy approach (including, but not limited to, geo-archaeological, GIS-based and statistical, palaeo-ecological) in order to detail and compare the magnitude of human impact in this crucial period across the Mediterranean region. Different scales of analysis are also very welcomed.

ABSTRACTS

1 FRONTIER TERRAMARE: PRELIMINARY PALAEOENVIRONMENTAL RECONSTRUCTIONS FROM THE TERRAMARE OF RONCHI DI CAORSO (PC)

Zappa, Jessica (Laboratorio di Palinologia e Paleobotanica, Dipartimento Scienze Vita, Università degli Studi di Modena e Reggio Emilia) - Scacchetti, Federico (AR/S Archeosistemi Società Cooperativa) - Bonometti, Paolo (AR/S Archeosistemi Società Cooperativa) - Mazzieri, Paola (Soprintendenza Archeologia, Belle Arti e Paesaggio per le Province di Parma e Piacenza) - Zerboni, Andrea (Dipartimento di Scienze della Terra "A. Desio", Università degli Studi di Milano) - Cremaschi, Mauro (Dipartimento di Scienze della Terra "A. Desio", Università degli Studi di Milano) - Carra, Marialetizia (Dipartimento di Storia Culture e Civiltà, Alma Mater Studiorum Università di Bologna) - Mercuri, Anna Maria (Laboratorio di Palinologia e Paleobotanica, Dipartimento Scienze Vita, Università degli Studi di Modena e Reggio Emilia)

The Terramare of Ronchi di Caorso is an archaeological site inhabited during the Middle and Recent Bronze age (3550–3170 BC), representing the westernmost Terramare village of the Po Plain, in northern Italy. In fact, archaeological material of both the classical Terramare production as well as more western productions were found during excavations, demonstrating a mixture of cultures and extensive exchanges at this settlement.

Preliminary palynological analyses were performed on 20 samples, coming from the west moat of the settlement. About 50 different pollen taxa were found, mostly belonging to non-arboreal plants (NAP). The forest cover, when present, is mostly represented by deciduous Quercus and other elements of the mixed oakwood (*Carpinus betulus*, *Ostrya carpinifolia*, *Corylus avellana*, *Tilia*, *Fraxinus excelsior* and *Acer campestre*). Additionally in the most recent phases of exploitation of the site we detected the presence of hygrophilous species as *Alnus* and *Pinus*, thus suggesting a cooler condition than in the previous phases. Among NAP, plants belonging to the API (Anthropogenic Pollen Indicators) and LPPI (Local Pastoral Pollen Indicators) groups are predominant, including especially cereals (*Avena*/*Triticum*, *Hordeum*), *Cichorieae* and other *Asteraceae*, *Brassicaceae* and *Ranunculaceae*. Generally, the pollen assemblage shows an open landscape, with very low forest cover around the site, that is mostly characterised by grasslands and synanthropic communities.

Many remains of cereals (grains, fragments, glume bases, spikelets) characterise the samples studied so far from a carpological point of view.

Among them, various species of wheat (*T. monococcum*, *T. turgidum* ssp. *dicoccon*, *T. spelta*), barley (*Hordeum vulgare*) and millet (*Panicum miliaceum*), accompanied by undetermined fragments of cultivated pulses.

Dogwood and elderberry are the food fruits attested with herbaceous and anthropogenic weeds (mainly *Chenopodium*, *Rumex*, *Lysimachia*).

Ash and deciduous oak are the first remains identified through the anthracological study, confirming what was reconstructed from the pollen analyses.

2 ENVIRONMENTAL CHANGES AT THE DAWN OF METALLURGY IN A PREHISTORIC ALPINE MINING REGION IN TRENTO, ITALY

Piazzalunga, Giorgio (Dipartimento dei Beni Culturali, Università degli Studi di Padova, Italy) - Dal Corso, Marta (Dipartimento di Geoscienze, Università degli Studi di Padova, Italy) - Avanzini, Marco (Ufficio ricerca e collezioni museali, Museo delle Scienze di Trento, Italy) - Bellintani, Paolo (Umst soprintendenza per i beni e le attività culturali, Provincia autonoma di Trento, Italy) - Silvestri, Elena (Umst soprintendenza per i beni e le attività culturali, Provincia autonoma di Trento, Italy) - Nicosia, Cristiano (Dipartimento di Geoscienze, Università degli Studi di Padova, Italy)

What was the environmental impact of early metal ore mining and metallurgy? Is it possible to detect it? Was it significant and lasting or limited and reversible?

We focus on human-environment interaction in a prehistoric mining district in the south Alpine region of Trentino (north of Italy). By studying palynological records in natural archives, we can provide diachronic evidence of anthropogenic activities through independent proxies, which help the understanding of socio-environmental dynamics in the area.

The southeast Trentino was a key spot for copper smelting activities between the III and II millennium BCE. Archaeological evidence identifies two phases: the first dates to the Late Copper Age – beginning of Early Bronze Age and it is distinguished by small scale and poor mastery smelting process, and by settlements in the valleys and the foothills. The second dates to Recent and Final Bronze Age, when copper ore exploitation took place on a larger scale, as testified by more than two hundred smelting sites in middle mountain areas. A chronological gap occurs in the local archaeological record: between the two phases smelting sites seem to be absent so far, although metal objects originating from Trentino ore can be found in contemporaneous European sites.

In the framework of the ERC CoG project GEODAP (Geoarchaeology of Daily Practices), stratigraphic, chronological and pollen analyses were carried out on two sediment cores from Lago di Caldonazzo (Valsugana) and from biotope Malga Laghetto (Lavarone plateau) to unravel the ecological consequences of metal production in this alpine region. The two sites differ in size, altitude, catchment area and therefore offer integrative viewpoints on the human influence on the ecosystems through time. By the distinction of deforestation, slash-and burn agriculture, shepherding and grazing, different land-use patterns could be tracked back and implement the reconstruction of the development of mining regions.

3 TRACING THE LONG-TERM ENVIRONMENTAL AND SETTLEMENTS DYNAMICS IN THE COASTAL PLAIN OF NE ITALY SINCE MIDDLE HOLOCENE

Azzalin, Mattia (University of Padua) - Vinci, Giacomo (University of Padua) - Donders, Timme (University of Utrecht) - Gerats, Wouter (University of Utrecht) - Fontana, Alessandro (University of Padua)

Besides the Lagoon of Venice, the other tidal and brackish environments characterizing the NW Adriatic Sea experienced an evolution of over 8000 years that strongly imprinted the available resources of the coastal plain and partly constrained past settlement dynamics. We analyzed some key areas where important paleo-ecological archives are available and the human occupation is documented since mid-Holocene. In particular, we focused on the area around Concordia Sagittaria and Aquileia, that became important Roman cities, but where large sites are attested since late Neolithic.

This research integrates LiDAR-derived DEMs, interpretation of remote-sensed images and detailed paleobotanic and micropaleontological analyses. The stratigraphic architecture of the coastal plain has been reconstructed through the use of over 5000 boreholes produced in the last 20 years in the framework of the collaboration between Padova and Utrecht universities, during student fieldworks and specific research projects.

Near Concordia Sagittaria a large incised fluvial valley was formed by the Tagliamento River during Late Glacial, separated by scarps of over 10 m high from the rest of the plain and up to 1500 m wide. Since around 8500 years BCE the marine transgression transformed this depressed landform into an estuary extending for over 15 km landward. This peculiar setting attracted prehistoric groups over the edges of this valley. At the same time, this fluvial incision represents a unique ecological archive with an almost continuous sedimentation until historical time.

Recent geological surveys documented the existence of other incised fluvial valleys near the city of Aquileia. In this sector, a number of brackish swamps formed since around 6000 years BCE have been detected and mapped allowing to record the evolution of the ancient human impact. Overall, these investigations open new perspectives for archaeological and paleo-environmental studies in the area, that corresponds to the northernmost lagoon zone of the Mediterranean.

4 EFFECTS OF ANTHROPOGENIC AND CLIMATIC CHANGES ON THE APENNINE LANDSCAPE DURING THE LATE BRONZE AGE: PALYNOLOGICAL EVIDENCE FROM CENTRAL ITALY

Vignola, Cristiano (Department of Environmental Biology, Sapienza University of Rome) - Bettelli, Marco (National Research Council, Institute of Cultural Heritage Sciences (CNR-ISPC)) - Cardarelli, Andrea (Department of Science of Antiquities, Sapienza University of Rome) - Di Renzoni, Andrea (National Research Council, Institute of Cultural Heritage Sciences (CNR-ISPC)) - Sadori, Laura (Department of Environmental Biology, Sapienza University of Rome)

In the Mediterranean region thousands of years of plant exploitation by human societies strongly impacted on the vegetation. Holocene pollen records in Italy revealed the imprints of economic activities on the landscape since the Bronze Age: changes in forest cover and the use of fire are clearly attested from the mid-Bronze Age in association with the expansion of cultivation and grazing. Since abrupt climatic oscillations occurred during this time span, they could exacerbate the effects of woodland clearance depauperating forest composition and structure, as well as causing erosion processes. In particular climatic, palynological, and geoarchaeological data indicates conditions of increased aridity during the Late Bronze Age and suggests different drivers of deforestation and soil exhaustion.

We present new pollen data from an in-site record of central Italy dated to the end of the Bronze Age. Sediment samples were recovered from anthropogenic deposits of Monte Croce-Guardia (Arcevia) spanning three centuries. The site is located on the Apennine ridge at 666 m asl and overlooks a wide territory from the mountain slopes to the Adriatic coast. Modern vegetation is dominated by the mixed deciduous oak forest typical of mid-altitude environments. Despite the pollen conservation bias due to taphonomic processes, palynological analysis shows that Mediterranean trees represented an important component of local vegetation, suggesting different climatic conditions during the Late Bronze Age. In addition to natural constraints, the abundance of xeric herbs could refer to a landscape modelled by human activities in the surrounding of the site, like grazing. The palaeoecological dynamics of central Italy will be further investigated in the frame of the NRRP project National Biodiversity Future Center, that aims to develop conservation plans for Italian protected areas by reconstructing past changes in animal and plant variability.

5 HUMAN IMPACT ON THE ENVIRONMENT AND LAND USE EVOLUTION: MULTI-PROXY ANALYSIS AT THE BRONZE AGE SITE OF "LA MURAIOLA" (ITALY)

Bandini, Beatrice (Department of Cultural Heritage, University of Padua, Italy) - D'Aquino, Silvia (Department of Cultural Heritage, University of Padua, Italy) - Polisca, Federico (Department of Cultural Heritage, University of Padua, Italy) - Breglia, Francesco (Department of Geosciences, University of Padua, Italy) - Dal Corso, Marta (Department of Geosciences, University of Padua, Italy) - Piazzalunga, Giorgio (Department of Cultural Heritage, University of Padua, Italy) - Nicosia, Cristiano (Department of Geosciences, University of Padua, Italy)

Since the Middle Bronze Age (MBA), the Po Plain experienced a demographic growth and a considerable increase in settlement size. Large embanked settlements, known as 'Terramare', spread as a result of a deliberate plan involving living areas and structured agricultural systems around the sites. The resources required by these settlements likely implied a significant impact on the environment, which can be traced through archaeological indicators of land over-exploitation.

Within the framework of the ERC CoG project GEODAP (Geoarchaeology of Daily Practices), this study presents the first results of archaeobotanical and micromorphological analyses from recent excavations at the MBA settlement of La Muraiola di Povegliano (Verona, Italy). The samples subjects of these analyses come from sequences that include the natural substrate before occupation, the paleosol on which the settlement is established and two macrophases of the site's life.

Anthracological analysis reveals human impact evidence on the environment from the beginning of occupation, marked by a potential deforestation through fire. Furthermore, data on the use of forest resources are presented and potential indicators of stress on tree vegetation are discussed. The carpological study highlights cereal cultivation as a fundamental economic activity for this community, suggesting a drastic change in land use, from a forested area to a settlement with its own subsistence economy. Micromorphological analyses have identified another anthropic activity that may have affected the environment, such as breeding in the initial phase of the site, providing useful insights for the functional interpretation of the anthracological assemblage in the second phase, where domestic waste associated with structural evidence is recognised.

A multi-proxy approach supports the hypothesis of an increasing anthropogenic impact on the surrounding area, which contributes to the scenario of overexploitation of the environment by Terramare communities during the Middle Bronze Age.

6 ENVIRONMENTAL IMPACT OF BRONZE AGE MONUMENTS: THE MOUND OF UDINE AND THE FRIULI PLAIN (NE ITALY)

Vinci, Giacomo (University of Padua) - Fontana, Alessandro (University of Padua)

Late prehistoric monuments are often the only remnants of complex cultural past landscapes and constitute the tangible product of widespread human-induced modifications on the environment. Recent geoarchaeological investigations including new stratigraphic cores drilled at the hill dominating the city of Udine (NE Italy) indicate the "Castle Hill" as the largest anthropogenic mound erected in Europe before Roman times.

Located in the middle of a vast alluvial plain, the mound measures 30 m in height and over 400,000 m³ and consists of alternations of gravelly and clayey lenses for its entire thickness. It was erected around 1400-1300 BCE, probably in a short lapse of time, by extracting the earth deposits from the surroundings. This excavation led to create a depression that was used as a water basin for supplying the coeval fortified settlement.

Paleopedological, botanical and geochronological investigations on the cores also allowed to reconstruct the environmental setting existing when the mound was built. In particular, pollen analyses enlightened clear signs of strong anthropogenic impact that occurred in the area even before the construction of the mound. These include the degradation and management of pristine forests, its conversion into open fields and the introduction of new species related to agro-pastoral activities.

As documented by a growing number of studies on coeval communities in the Po Plain (Terramare Culture), both the archaeological and palynological data from Udine and other fortified settlements in the Friuli Plain demonstrate unprecedented landscape changes and human impact on the alluvial environments of northern Italy since the second half of the 2nd millennium BC. At the same time, the monumentality of the Castle Hill opens new perspective on the study of labor organization, land management and, ultimately, on the demography of these Bronze Age communities.

7 RECONSTRUCTING LONG-TERM HUMAN IMPACT IN CENTRAL ADRIATIC ITALY USING LEGACY AND NEW DATASETS

de Neef, Wieke (Otto-Friedrich Universität Bamberg)

This contribution discusses methodological challenges in the reconstruction of pre-Roman human-environment interactions in Central-Adriatic Italy. Our understanding of pre- and protohistoric impact on the hilly landscapes between the Apennines and the Adriatic coast remains fragmentary. This can partly be explained by research biases, including a focus on burial contexts and fieldwork preferences for easily accessible agricultural land. Further obscuring factors are the extensive 20th century reforestation programs in the mountainous inlands, the poor preservation of botanical remains in a series of recent excavations, and the lack of high-resolution LiDAR data for large parts of the Adriatic (pre-)Apennine ranges. However, legacy excavation contexts and environmental proxies from a wider region provide extra information. Combined with new fieldwalking data and geophysical surveys, these proxies can now be used to piece together the long-term human impact history of the present-day regions of Marche and Abruzzo. In this presentation, I illustrate the challenges of using fragmentary data for such reconstructions with recent research in the Potenza and Misa valleys (Marche).

8 THE ORIGIN OF LANDSCAPE INSTABILITY IN THE FOURTH MILLENNIUM BC OF THE TROIENESE OF UPLAND SICILY

Marras, Gian (University of Cambridge) - Stoddart, Simon (University of Cambridge) - Schmidt, Frjida (University of Cambridge) - French, Charles (University of Cambridge) - Malone, Caroline (Queen's University Belfast)

The central region of upland Sicily has a unique landscape of vast pasturelands and croplands that mantle gently to steep sloping rounded hills. However, these slopes are affected by the intense mobilisation of soil materials which leads to different forms of surface erosion and downslope deposition. When did slope instability start to occur across the landscape of upland Sicily? What is the role of prehistoric settlement in driving past and ongoing geomorphodynamic processes? To address these questions, in this work, we will focus on slope deposits of the Troina intermontane valley located within the Nebrodi Mountain Range of central Sicily. In particular, a detailed lithostratigraphic analysis of deposits has been carried out on the occasion of an archaeological excavation that opened various trenches on a midslope position along the western flanks of the Troina valley. Geochronology through radiocarbon dating and micromorphology on undisturbed block samples from the different investigated units have been undertaken to establish the absolute chronology, processes, and causes at the origin of these deposits. Following an integrated approach of lithostratigraphic analysis, soil micromorphology, and radiocarbon dating, this work sheds new light on the origin of the landscape instability that characterises present-day upland Sicily. By combining and discussing data from previous geoarchaeological research that highlighted several phases of erosion and deposition along the Troina Fiume di Sotto Valley, and regional fossil pollen sequences, this study unravels the impact that Copper Age communities at ca. 5,000 BP had on driving geomorphic trajectories across the central upland region of Sicily.

1102 STRATEGIES TO RULE THEM ALL. A TRANSNATIONAL ANALYSIS OF LANDSCAPE CONTROL AND SCALES OF POWER BETWEEN 5-16TH CENTURIES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Blanco Torrejón, Laura (Universidad de Salamanca) - F. Pereiro, Mario (Institute of Archaeology (University College London)) - Ramos Soriano, Mario (Universidade de Santiago de Compostela) - Baeza Gomariz, Leonor (University of Salamanca) - Sánchez Serrano, David (Rey Juan Carlos University)

Session format: Regular session

Regarding the different theoretical perspectives formulated in recent times about territorial control and the exercise of power in pre-capitalist societies, there is one indisputable idea: there is no unique and simple strategy that allows such control. In order to understand those phenomena, in this session we will seek to analyse the strategies of landscape control and its archaeological records between the 5th century and the 16th century, adopting a worldwide comparative perspective.

Most societies express their landscape power through the application of many coercive measures ranging from punitive actions to less obvious ones, such as tax control or the creation of an ideological control system. All these tools are used in a multiscale way by the different social groups of a community which leaves a remarkable archaeological footprint (i.e. fortifications, agricultural exploitation, religious buildings, burials...)

Having this in mind, how do these actions affect the rest of the community? How do the dominated classes face these strategies of territorial control? Do the strategies of local or supralocal powers change or adapt to deal with active or passive resistance? And above all, how can we report all these changes through Archaeology?

ABSTRACTS

1 ABULA (ÁVILA, SPAIN) AS A CENTRAL PLACE IN LATE ANTIQUITY HISPANIA THROUGH VISIGOTHIC SLATES

Sánchez Serrano, David (Universidad Rey Juan Carlos)

The Late Roman city is the result of an economic and social process that started at the end of the second century (ARCE, 2023), undergoing changes in its urban physiognomy (GURT y SÁNCHEZ, 2009; DIARTE, 2015). The processes of transformation that have taken place since the Late Roman period reveals a process of regionalization that prevents the extrapolation of conclusions from other areas. Thus, the application of the term city in the Douro Valley is imprecise (TEJERIZO, 2015), while its status as a Roman civitas barely distinguishes it from other central places between the 5th and 7th centuries.

Abula was a city of relative importance during the Imperial period, as a result of which it would be configured as an episcopal see with Priscillian since the year 380 (BALMASEDA, 1998); this led to the early Christianization of the city with the consequent transformation of its physiognomy (BARRACA, 2012; FABIÁN, 2021), giving rise to a settlement that could well be inserted into the category of first generation castles (TEJERIZO, 2015). The status of Abula as an episcopal see since the 4th century and the concentration of numerical slates around the settlement, as well as the existence of drawing slates with religious themes, could suggest the association of this intense accounting activity with the religious and civil authority of the central place. According to the data, nothing seems to deny the status of central place for Late Antique Abula, whose materiality, especially the number of slates found, is comparable to other hierarchical sites of the Douro.

2 SIMILARITIES AND DIFFERENCES IN POWER'S EXERCISE BETWEEN CORNWALL AND GALICIA DURING EARLY MIDDLE AGES (5TH TO 10TH CENTURIES)

Soriano, Mario (Universidad de Santiago de Compostela; CISPAC)

As a consequence of the fall of the Roman state, new territorial powers emerged that largely replaced it. These had limited success over time, as they generally ended up falling. In this situation of weakness of state power, new strategies for territorial control were developed, which would end up leading in subsequent centuries to the construction of early medieval states, with important differences in the various geographies of the Mediterranean and the Atlantic. However, despite the fact that great narratives have been offered about the general transformations, we still do not understand in depth its mechanisms or the processes related to it in its entirety in certain spaces, such as the northwest of the Iberian Peninsula or the Southwest of Great Britain. But do both societies respond the same to this situation? How is this response given? Then, is it comparable? What can offer archaeological analysis to our comprehension of the period? That is why with we are doing this presentation: to provide a working hypothesis that answers that questions. Thus, it will be discussed how the exercise of these post-Roman and pre-feudal powers occurred in the aforementioned geography, by the analysis and comparison of the archaeological record of two small peninsulas: West Penwith (Cornwall) and Barbanza (Galicia).

3 WHY BUILD A CASTLE IN EARLY MEDIEVAL GALLECIA (8TH-11TH CENTURIES)? REFLECTIONS ON THE NEEDS OF TERRITORIAL CONTROL

Pereiro Fernández, Mario (Universidade do Minho; Universidade de Santiago de Compostela)

The use of fortified sites of military origin is a constant for the control of a certain territory. This phenomenon will proliferate in much of Europe in the central period of the Middle Ages, with the appearance of elite strongholds and strategic fortifications. Functionally born for the control and defense of a specific territory, these constructions will end up forming part of the administration of the landscape and the evolution of the state in this period. For Gallecia, northwest of the Iberian Peninsula, it is a phenomenon that is documented as beginning in the middle of the 8th century. It is interesting to identify the different adaptations that this type of fortifications have, from initiatives by aristocratic powers to their use by state-level projects. The archaeological study of these strongholds allows us to identify certain construction and location patterns that adapt to the needs of their owners within the political reality in which they are inserted.

4 DEATH AND LANDSCAPE. POWER, CONTROL AND LEGITIMATION THROUGH THE BURIALS DURING THE 8-11TH CENTURIES AD IN THE NW IBERIAN PENINSULA

Blanco Torrejón, Laura (University of Salamanca)

When we think about territorial control during the Early Middle Ages, we usually highlight the building of complex structures such as fortifications or the imposition of a certain political and economic system. However, this control

can be exercised through a more simple and daily action: the reuse and creation of funerary areas. This paper aims to explore the socio-political trends that have their direct reflection in the landscape management by local elites via the establishment of a series of isolated or small groups of anthropomorphic burials. This important amount of sarcophagus and rock-cut graves scattered across the north-western part of the Iberian Peninsula are often the only remains that we have from this social group. The locations of these inhumation areas are not random, they respond to strict strategies to legitimate its power into its territory due to a visual and mnemotechnic technique known by the whole community. Along these centuries we witness differences in the morphology and conformation of the funerary areas, at the same time as the political power change between local elites, aristocratic circles supported by the Astur-Leonese kingdom, and the Church. Thus, political, social and economic dynamics that function as starting points for the flourishing of modern states.

5 PEASANT PLACES. RECONSTRUCTING THE MEDIEVAL PEASANT LANDSCAPE IN NORTHERN IBERIA (9TH-11TH CENTURIES)

Baeza Gomariz, Leonor (University of Salamanca)

This paper aims to study the spatial organisation established by different social agents in the Liébana region (Cantabria, Spain) between the 9th and 11th centuries, through the study of its landscape.

Since the 1990s, historical research has made progress in understanding the landscape as an expression of the collective identity of the community, which expresses its territoriality through the appropriation, exploitation, and defence of the space it recognises as its own.

The aim is to insert the local communities in their spatial context, deploying a wide range of analyses, firstly, through the use of GIS (visibility, isochrones of the villages, optimal routes to the cultivation areas and their adaptability to the soil). And, secondly, through the phenomenological study of the landscape based on the information preserved in early medieval documentation (mainly the Charters of Santa María de Piasca and Santo Toribio de Liébana). This double approach allows us to analyse the perception of the landscape by the social agents, as well as to try to understand the spatial organisation and to put forward hypotheses for its topographical reconstruction in the landscape.

This paper will present the results of the application of this methodology in the current municipality of Cabezón de Liébana. Here, in a territory under the influence of a supralocal agent such as the monastery of Santa María de Piasca, we observe a peasant population, interconnected by a network of secondary roads, which carried out the exploitation and management of its territory to its maximum potential. There is evidence of their own internal organisation and hierarchy, in matters of spaces demarcated according to other neighbouring agents (whether local or not), or in their assessment of the value of primary and secondary products (animals, cereal, wine, tools...). All this as part of an internal process of non-aristocratic social differentiation.

6 THE CREATION OF AN EARLY MEDIEVAL REGIONAL HIERARCHY FROM WITHIN. EXPLORING THE MONASTIC LANDSCAPES OF SAMOS AND MONTE AMIATA ABBEYS

Sanchez-Pardo, Jose Carlos (University of Santiago de Compostela) - Fernández Ferreiro, Marcos (University of Santiago de Compostela) - Blanco-Torrejón, Laura (University of Salamanca) - Rodríguez González, Celtia (University of Santiago) - Santos-Salazar, Igor (University of Trento) - Farinelli, Roberto (University of Siena)

Monasteries often became main spatial and political nodes of rural territories in the early Middle Ages, especially in areas with a smaller or weaker presence of urban centers. Through purchases, donations and other strategies, some monasteries were able to create important areas of lordly dominion, controlling villages, agrarian spaces and productive infrastructures. However, the study of monastic domains has traditionally been carried out only employing the written information left by the monasteries themselves, and often from a top-down theoretical perspective in which monastic power is directly imposed on peasant communities. In this presentation, we will summarise the main results of the ARPAMED and ECOLOC projects, funded by the Spanish Ministry of Science, in which the monastic landscapes of the abbeys of Samos (Northwest Spain) and Monte Amiata (Central Italy) are studied and compared in an interdisciplinary way. The combination of macro-scale analysis of the controlled territories using Geographic Information Systems together with micro-scale archaeological fieldwork in the villages and agricultural spaces that formed part of both monastic domains allows us to model more complex and diachronic interpretations of the establishment of spatial networks of power and socio-economic relations in the Early Middle Ages in Galicia and Tuscany.

7 CONFLICT AND INTEGRATION: A DISCUSSION ON THE NORMAN CONTROL SYSTEM OVER LOMBARD BENEVENTO BETWEEN XI AND XII CENTURY

Ricchiuti, Daniele (Sapienza Università di Roma)

Between early XI Century and the first half of XII Century the Normans built in Northern Campania a strong feudal network, meant to guarantee control over lands and people. In addition to defense and exploitation of fiefs, a key

aspect in this system was, of course, the interaction with the (mainly) Lombard population living in the region: as conquerors, Normans imposed their rule on them, but at the same time, this new aristocracy interacted deeply with its subjects, defining a very complex relationship.

This is especially true for Benevento: a city not only ethnically Lombard, but also politically subject to direct papal rule. Rather unsurprisingly, this situation determined a tense relation between Benevento and the neighboring Norman powers. Here fundamental questions arise: how local Norman barons dealt with this autonomous Lombard enclave? Were they capable to impose a strong (even if indirect) rule over the city and the surrounding landscape?

Answering these questions, a first key-element is the survey of known fortification around Benevento: we will map known Norman strongpoints around the city, merging archeological and architectural data with information provided by written sources. This should allow us not only to carry out spatial analysis with a GIS software (especially regarding visibility), but also to evaluate the relation between this fortified backbone and strategic assets like roads.

In addition to these mainly archeological data, we will also focus on written sources to evaluate other aspects which were part of the same Norman system of landscape control. In particular, the paper will deal with warfare (through the analysis of different campaigns) and economic and fiscal tools used by the ruling Normans.

All these data will help us in the defining a complex scenario, in which conflict and hegemonic rule were deeply related with forms of political and economic integration.

8 MEDIEVAL COLONISATION AS AN EXPRESSION OF SUPRALocal POWERS

Mazackova, Jana (Masaryk University) - Zaza, Petr (Masaryk University) - Vaneckova, Daniela (Masaryk University)

Reconstruction of medieval colonisation of the Bohemian-Moravian Highlands (Czech Rep.) has been analysed based on systematical research of the Rokštejn Castle and its closer hinterland. This highland was not settled until the 12th century, and as such represents a sort of a power vacuum. Landscape is thus anthropologically changed during and after this period, which lasts until the end of the 13th century, when we can presume the political structures stable, as is evident through parcelation of the landscape (mainly field systems). Yet, the fortification systems in and around the Rokštejn lordship do not correspond with the agricultural landscapes, clearly demarcated by anthropogenic features (e.g., ridge and furrows). Analysis of historical and archaeological data can further be used for recreating the political situation on local and regional scale, however, power is certainly represented by the settlement structure, as it is in itself, a way of controlling the population through taxes, resource allocation, and other revenues the political extent of the lordship's power allows.

1103 EMBODIED IDENTITIES: UNRAVELING SYMBOLIC THREADS THROUGH ORNAMENTS, GARMENTS, AND PORTABLE OBJECTS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Kurawska, Aldona (Institute of Archaeology and Ethnology Polish Academy of Sciences) - Baysal, Emma (Department of Archaeology, Ankara University) - Sobkowiak-Tabaka, Iwona (Faculty of Archaeology Adam Mickiewicz University) - Cartolano, Mattia (University of Bologna) - Yelözer, Sera (National Geographic Society funded Small Things Big Stories Project)

Session format: Regular session

Personal ornaments, encompassing a diverse array of modified or unmodified objects, have left an indelible mark in the archaeological record. Beads, pendants, necklaces, bracelets, and other adornments crafted from natural and human-made materials seamlessly integrate with garments, collectively altering the body's appearance. Their visibility and durability suggest shared cultural significance beyond personal needs, prompting interactions within and between social groups. Worn to stand out within communities, distinguish from other groups, facilitate communication, denote status, role, marital status, age group, and tribal hierarchy, ornaments played a multifaceted role in societal dynamics throughout prehistory.

In parallel, recent research has shed light more broadly on portable symbolic elements of material culture like ornaments, plaques, and figurines, as well as tools and handheld devices with incisions or patterns. Despite receiving less scholarly attention than monumental structures, these items hold immense significance in understanding the symbol-making and communication traditions of prehistoric communities. They offer valuable insights into the lives and identities of individuals and groups, with contextual nuances revealing details in burials, domestic spaces, or waste deposits. Manufacturing techniques, decoration styles, and material composition provide essential information about artisans and systems of exchange.

This session welcomes contributions exploring evidence of body adornment practices and portable symbolic items, emphasizing their significance in shaping identities, meanings and symbolically charged communication. From personal ornaments in burial contexts to the interpretative potential of small finds, we invite diverse perspectives on dia-

chronic changes, social systems, and innovative theoretical approaches to deepen our understanding of the intricate relationships between bodies, identities, and material culture throughout prehistory and beyond.

ABSTRACTS

1 SHELL ORNAMENTS OF GRAVETTIAN COMMUNITIES: MOBILITY AND SOCIAL IDENTITY IN UPPER PALAEOLITHIC POLAND

Kurzawska, Aldona (Faculty of Archaeology, Adam Mickiewicz University) - Wilczyński, Jarosław (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Department of Vertebrate Zoology) - Apolinarska, Karina (Institute of Geology, Adam Mickiewicz University) - Mrozek-Wysocka, Małgorzata (Institute of Geology, Adam Mickiewicz University) - Głód, Anna (Institute of Archaeology and Ethnology, Polish Academy of Sciences)

Ornaments from various studies primarily related to the Palaeolithic period serve as tools to explore the communication of personal identity or group affinity, exchange and social networks, management strategies, and finally, the ethnolinguistic diversity of human groups. The discovery of ornaments made from shells originating from the Mediterranean has significant implications regarding the identity of Upper Palaeolithic communities in Poland, the establishment of movement directions, the mobility and connections among groups. However, these exceptional finds are consistent with those related to other communities in Central Europe. Despite their uniqueness, these ornaments do not stand out in their type or form from the known Upper Palaeolithic tradition; instead, they confirm their belonging to it.

In this study, we analyze distinctive shell ornaments discovered at two archaeological sites associated with Gravettian communities. We discuss the implications of these particular ornaments in understanding human mobility and social identity. Therefore, a comprehensive analytical, comparative, and microscopic study is conducted, encompassing taxonomic identification of shells, determination of stable isotopes of carbon and oxygen for source recognition, use-wear examination of the ornaments, and analysis of the residues present on them. The study also investigates technological and taphonomic modifications of the material and compares this collection with the use of similar shell ornaments in the broader Upper Palaeolithic world. We address several issues, including the use of shell ornaments by Gravettian groups, exploring diversity in raw material sources, and the selection of specific types by humans. The procurement of ornaments from a great distance may be indicative of expanding social networks during the Upper Paleolithic.

2 DIACHRONIC EVOLUTION AND GEOGRAPHIC DIFFERENTIATION IN LATE EPIGRAVETTIAN SOCIETIES: BIOGRAPHICAL APPROACH TO ORNAMENTS FROM TAGLIENTE ROCK-SHELTER (VERONA, NE ITALY)

Hoareau, Leïla (CEPAM UMR 7264) - Fontana, Federica (Università di Ferrara) - Beyries, Sylvie (CEPAM UMR 7264, CNRS)

The biographical approach to archaeological objects makes it possible to grasp all the stages of life and observe the many cultural choices made during the life of the objects. Applied to ornamental objects, this approach offers the possibility of perceiving the place of ornamental practices in the social life of past societies. The typology of the objects is considered to be central to the definition of ornamental practices, but other aspects of their biography may have social and cultural significance: the methods of manufacture, the way in which they were assembled into a particular ornamental composition, and the ways in which the objects were abandoned are all significant biographical events.

We used this biographical approach to study the corpus from Tagliente rock-shelter, which contains several hundred marine shell ornaments documenting ornamental practices in the early Late Glacial period (16,000 - 14,000 cal. BCE). This has revealed a partial evolution in ornamental practices, affecting only shell selection and technical choices, while ornamental compositions remained stable. The choice of shell species reflects both a possible adaptation to resource availability, which was strongly affected by Late Glacial environmental change, and a reliance on networks of connections with distant groups. In addition, the choice of species and the way they were assembled in different ornamental compositions reveal regional practices, pointing to a differentiation of groups through their appearance within the vast Epigravettian techno-complex.

3 NEW DATA ON THE LATE MAGDALENIAN SYMBOLIC CULTURE IN POLAND

Plonka, Tomasz (Institute of Archaeology University of Wrocław) - Przeździecki, Michał (Faculty of Archaeology Warsaw University) - Diakowski, Marcin (Institute of Archaeology University of Wrocław) - Niedźwiedzki, Robert (Institute of Geological Sciences University of Wrocław) - Ziółkowski, Grzegorz (Faculty of Mechanical Engineering Wrocław University of Science and Technology)

In the thirteenth millennium BC, southern Poland was a flourishing area of Late Magdalenian settlement. Stone artefacts typical of Magdalenian flintwork have been found at sites from this period, as well as objects relating to the symbolic world of Magdalenian foragers: anthropomorphic figurines, engravings, pendants and pigments.

In recent years, we studied new symbolic artefacts excavated at the site Ćmielów 95 in Lesser Poland, at Birów in Upper Silesia, and near Wschodnia Cave at Wojcieszów in Lower Silesia. The last two were stray finds, a fragment of a reindeer tine with rows of drilled points and a perforated bear rib, both directly dated by radiocarbon. In examining ornamentation, we used microscopic observations, tomographic method (CT) and experiments.

The most complete set of artefacts from Ćmielów included fragments of pigment, fossils, stone slabs with engravings and fragments of two ornamented rondelles made of red pigment. Analysis of the fossils, rocks and pigments showed that they came from the vicinity of the site. The engravings are composed of geometric motifs; most of the engraved lines were repeated. Research on the objects from Birów and Wschodnia Cave allowed us to determine the method of their production (drilling, cutting).

Late Magdalenian symbolic artefacts from Poland show features specific to finds from Central and Western Europe. So far, there are no figural engravings here, and the female figurines typical of Magdalenian were made of stone - mainly flint, using knapping, and the rondelles known from this area were made of red pigment. These data allow us to conclude that the Late Magdalenian foragers from the area of today's southern Poland had a specific and original symbolic culture with numerous local accents.

4 MESOLITHIC TRADITION IN NEOLITHIC CONTEXT - PERSONAL ORNAMENTS IN FUNERARY PRACTICES OF CENTRAL EUROPE: A CASE STUDY FROM POLAND

Głód, Anna (Institute of Archaeology and Ethnology Polish Academy of Sciences) - Kurzawska, Aldona (Faculty of Archaeology Adam Mickiewicz University) - Apolinarska, Karina (Institute of Geology, Adam Mickiewicz University) - Sobkowiak-Tabaka, Iwona (Faculty of Archaeology Adam Mickiewicz University) - Żurkiewicz, Danuta (Faculty of Archaeology Adam Mickiewicz University)

During the Neolithic period in Europe, there was a notable increase and dissemination of personal ornaments. This was believed to be primarily driven by changes in the social organization of Neolithic communities, advancements in craft production, exchange networks, and the procurement of raw materials. Throughout this period, a consistent pattern of continuity and change in the utilization of personal ornaments is discernible, both across time and geographical regions. Present-day Poland, situated on the periphery of influences mainly from the south (specifically, the Danubian influences from the Transcarpathian area), experienced the impact of these influences primarily through the introduction of foreign materials and different traditions. However, a substantial number of ornaments were crafted from locally available materials. Among these, there are ornaments characteristic of Mesolithic populations in Eastern, Central, and Southern Europe: beads made of small snail shells, pendants made of animal teeth, bone bracelets, arm-lets, and boar tusk pendants. These artifacts were discovered in the region of present-day Poland exclusively in richly equipped female burials associated with early Neolithic communities in the second half of the fifth millennium BC.

In our presentation, we delve into the use of these "Mesolithic" ornaments in multi-elemental decorations such as hip belts, headdresses, and appliques, often composed of hundreds of beads made from various materials. We offer a comprehensive analysis of these ornaments concerning their identification, sources of procurement, along the identification traces of their use. All of this is aimed at revealing their significance as visual markers of identity, social status, symbols of wealth and prestige, reflections of traditions, ancestor legacies, beliefs, and rituals. Furthermore, we explore whether these ornaments reflect intensive interactions between early farmers and hunter-gatherers or if they were brought by agricultural communities originating from the southern regions.

5 SMALL THINGS, BIG STORIES: BODILY IDENTITIES AT THE NEOLITHIC TRANSITION IN SOUTHWEST ASIA

Baysal, Emma (Ankara University)

The Neolithic transition saw some fundamental changes in the way that people interacted with both the world around them and with each other, which can be traced through their personal ornaments. The small items of material culture associated with the human body are rich sources of information not only about past materials and technologies, but also about the people who made and used them. In this presentation I will use studies of personal ornaments to explore what we can find out about identities at the dawn of the Neolithic, with the aim of centring people and their experi-

ences in the interpretation process. Using the case study of in situ burials from Boncuklu Tarla, southeast Türkiye, I will look at human-jewellery relations at both macro and micro scales to identify community and individual experiences of identity creation and communication. Analyses of the objects that people associated with their bodies, and in some cases, artefacts that transgressed bodily boundaries in a process of physical transformation, will be used to consider perceptions of age, sex and status within this early sedentary society. In conclusion the presentation will consider wider questions of time, ownership and communication as expressed in personal ornaments.

6 LEAF-SHAPED MOTIF IN NEOLITHIC ENGRAVINGS. A DISCUSSION OF IMAGE PRODUCTION AND INTERPRETATION OF PORTABLE OBJECTS

Cartolano, Mattia (University of Bologna)

The Neolithic in south-west Asia is a key transitional period in which prehistoric communities adopted new lifestyles and produced a wider range of symbolic artefacts. The extraordinary monumental architecture adorned with chiselled figurative images and the mortuary practices of detached skulls have received particular attention in recent years. On the contrary, small items such as beads, plaques and shaft straighteners have not been extensively analyzed. This presentation will focus on the markings visible on these small finds retrieved from Pre-Pottery Neolithic (ca. 9700-6600 BC) in southwest Asia.

Leaf-shaped motif consists of a set of specular incisions of parallel oblique marks joined by a straight line in the middle. This type of engraving can be observed on portable items found at Pre-Pottery Neolithic sites such as Demirköy, Tell 'Abr, Tell Qaramel, Mureybet and others. What is interesting is that these marks are sometimes situated along with other incisions and have never been examined comparatively. The present work aims to deep dive into the analysis of leaf-shaped incisions in Neolithic portable objects in order to assess the significance of these engravings for late hunter-gatherers and early farming communities with regard to personal and community identity and symbolic communication.

7 A NEOLITHIC TECHNOLOGICAL APPROACH TO THE PRODUCTION OF STONE BEADS: INSIGHTS FROM THE ANALYSIS OF THE NAHAL HEMAR CAVE ASSEMBLAGE

Bar-Yosef, Daniella (Steinhardt Museum of Natural History) - Porat, Naomi (Geological Survey of Israel) - Groman-Yaroslavski, Iris (University of Haifa)

The stone beads assemblage of Nahal Hemar Cave, southern Israel, was analyzed to reconstruct the technology applied by artisans during the Pre-Pottery Neolithic B (9,900-9,400 cal BP). The study of 35 beads recovered at the site highlights three main inter-related aspects: a broad range of raw materials used, the workmanship necessary for the production of the beads in accordance with their types, and the fashioning of beads into types that are suitable for a particular method of using them. Raw material identification was based on SEM-EDS analyses. Eleven minerals identified provide a clue to the vast geographical range from which they were extracted. The typological characterization showed that beads have mostly a round and lenticular transverse section. Based on experimentation we found that the makers of the beads had an intimate acquaintance with the properties of the minerals. The microscopic wear analysis indicates the methods of abrasion and polishing, where the round beads are rolled and the lenticular beads are abraded on a flat surface. The analysis also indicates selective methods of drilling and binding that are consistent with bead types. We conclude that decision-making processes in bead production took into consideration the constraints posed by the properties of the stone and the tools that were used for manipulating them. This technological approach reflects a consolidated framework of careful planning and execution that contributes to the wider perspective of novel trends of the Neolithic period paralleling other developments associated with the establishment of village life and agriculture.

8 THE PRODUCTION AND UTILIZATION OF PLASTER BEADS FROM NAHAL HEMAR CAVE: A MULTI-DISCIPLINARY APPROACH

Shafir, Yaara (Zinman Institute of Archaeology, School of Archaeology and Maritime Civilizations, University of Haifa) - Groman-Yaroslavski, Iris (Zinman Institute of Archaeology, School of Archaeology and Maritime Civilizations, University of Haifa) - Friesem, David (University of Haifa) - Bar-Yosef Mayer, Daniella (The Steinhardt Museum of Natural History, Tel Aviv University)

The Pre-Pottery Neolithic B period (PPNB 10,500-8,400y BP) in the Levant is known for the expanding sedentary farming lifestyle attended by an emerging social differentiation within the growing human population. This transition is represented inter alia by the production and use of personal ornaments and beads, usually made of shells and colorful stones, and by elaborate funerary practices, with special attention to the skull. In this context, the color-coated plaster beads from Nahal Hemar Cave in the southern Judean Desert (dated to ~9,000y BP) are unique, since although plaster was extensively used for construction, burials and decoration, this is the only known case of plaster beads.

Employing a multi-disciplinary approach combining methods of morphological, mineralogical and use-wear analysis, this study aimed to reveal the production techniques and raw-material sources of the beads, as well as their possible modes of use. The results showed that the beads were produced in the vicinity of the small cave in which they were stashed, and contrary to suggestions made by previous studies, were most likely made without pyro-technology. This was tested in a re-creation experiment, in which plaster beads were produced using unheated calcite rocks and the modeling methods identified in the morphological analysis. The use of non-pyrogenic plaster shifts the discussion away from the Neolithic lime plaster industry toward the versatility of Neolithic artisans and their aesthetic and technological choices. While the specific use and meaning of the beads remain unclear, their presence in the context of the mortuary items found in the cave and the minimal wear on the delicate beads, suggest that they may have been used as decoration for the dead rather than worn by living people.

9 BEADS AND IDENTITIES AT AŞIKLI HÖYÜK: A NETWORK OF RELATIONSHIPS

Yelözer, Sera (Small Things, Big Stories Project funded by National Geographic Society, Istanbul, Turkey) - Pereira, Daniel (Centre National de la Recherche Scientifique (CNRS), UMR-5199 PACEA, Bordeaux, France) - Rigaud, Solange (Centre National de la Recherche Scientifique (CNRS), UMR-5199 PACEA, Bordeaux, France) - Duru, Güneş (Mimar Sinan Fine Arts University, Istanbul, Turkey)

Because beads can be assembled and carried on the bodies, disassembled to be distributed between individuals and groups, they play a central role in conveying symbolic messages and creating social and cultural ties within and between communities. When found in funerary primary contexts and analyzed with appropriate methodology, personal ornaments provide a clear snapshot of how they were associated with specific biological sex and age categories, and in some cases habitual activities visible through osseous stress markers. By crossing personal ornament data, funerary practices and bioanthropological data it is thus possible to discuss if socially constructed concepts such as gender, social age, personhood, and kinship were materialized through personal ornament associations and position on the bodies within past societies. One way to approach these themes is through the analysis of the bead-type associations between individuals buried within a site.

In this study, we report the preliminary results from a range of statistical analyses (analysis of variance, SNA and PCoA) applied to a dataset of 30 individuals and their ornaments from Aşıklı Höyük, a Pre-Pottery Neolithic site in Central Anatolia, Turkey. We performed the analysis in the R software extending an already published Archaeological Similarity Network analysis protocol (Pereira et al. 2023). The analyses show that bead-type presence/absence and counted data provide different results. Bead-type associations significantly differ between age classes, and the sex of the individuals who wore them. The analysis highlights stylistic similarities between some of the adult females and sub-adults and also identifies some groups which cannot be explained by age class, sex or spatial proximity within the site. These results suggest that while age and sex may have played a role in bead-type similarity between some individuals, other social and cultural factors, that still need to be discussed, also influenced the observed diversity.

10 ORNAMENTS OF IDENTITY? DOUBLE-HOLED TRAPEZOIDAL CHALCOLITHIC PENDANTS AS A CULTURAL MARKER IN THE SOUTHERN LEVANT

Golani, Amir (Israel Antiquities Authority)

Cultural identity is often defined through archaeological material culture and can be distinguished in personal adornments. This is not surprising as bodily ornamentation is one of the most personal expressions of cultural identity imaginable; wearing them transmits information. A methodology developed in previous research has often shown that if a distinctive form, decoration and mode of use associated with jewelry has a clearly defined geographical and chronological dispersion related to a defined cultural entity, it can be seen as a cultural marker that identifies the wearer with a cultural group.

In the southern Levant, material culture remains associated with the Late Chalcolithic period (4500-3800 BCE) in funerary and non-funerary contexts alike frequently include a distinctive pendant of trapezoidal/rectangular form, usually with two holes at one end and often decorated in a distinct fashion. These pendants are usually made of shell, though bone, ivory and various stone examples are also found.

The morphological and technological concept of these pendants may have had their antecedents in the region of Anatolia during the 9th-8th mill. BCE, yet in the southern Levant, they first appear only during the Late Chalcolithic period and do not continue in use afterwards, suggesting they be seen as a cultural marker of the local Chalcolithic population.

11 PERSONAL ORNAMENTS FROM OSSEOUS RAW MATERIALS AND MOLLUSC SHELLS IN THE LATE NEOLITHIC IN EASTERN BALKANS

Vitezovic, Selena (Institute of Archaeology, Belgrade)

Recent discoveries at three Late Neolithic sites in the eastern Balkans, specifically within the Thrace region in Bulgaria, have revealed rich portable findings. Notably, these discoveries include large collections of personal ornaments intricately crafted from various osseous materials—bones, teeth, and marine mollusk shells—acquired either locally or through exchange routes. Noteworthy techno-types encompass simple forms with a broad geographical and chronological reach, such as bracelets made from marine bivalve shells, while others indicate local cultural traits, like cylinders made from long bones. These items were meticulously produced and often adorned with incised motifs or dots, presented as unfinished perforations. The array of ornaments extends to include pendants and decorative pins of diverse, unique, or rare shapes, potentially reflecting the individual artisans who created them and/or those who wore them.

In the broader context, the technological procedures employed in crafting most ornaments reveal substantial investments in labor, time, and skill. Significantly, wear observed on these ornaments suggests prolonged usage before eventual disposal due to breakage or loss. The combination of a high production investment and extended use implies significant value and significance attached to these items. It is reasonable to assume that they served as displays of status and identity, whether for a group or an individual. This paper aims to analyze possible connections between the raw materials, technological procedures, and the invested time and skills with the symbolic meaning and significance of these ornaments within the local communities.

12 BEYOND WARRIORS: INVESTIGATING LATE NEOLITHIC FEMALE BURIALS THROUGH COPPER ORNAMENTS

Sobkowiak-Tabaka, Iwona (Adam Mickiewicz University) - Kurzawska, Aldona (Institute of Archaeology and Ethnology, Polish Academy of Sciences) - Przybyła, Marcin M. (Dolmen Company, Kraków) - Włodarczak, Piotr (Institute of Archaeology and Ethnology, Polish Academy of Sciences)

The imperative of aesthetically treating the body of the deceased has been a crucial aspect of funeral rituals since the 3rd millennium BC, persisting through the Bronze and Iron Ages and intricately connected with the evolving trend of individualization. This phenomenon has significantly shaped the ideological landscape of European communities, particularly towards the conclusion of the Stone Age. These practices held considerable importance across diverse age and gender categories. While the emphasis on aesthetically treating the deceased is prominently observed in the category of adult men, commonly known as the warriors' beauty, our presentation will shift the focus to recently discovered women's graves in southern Poland. Within these burials, remarkable sets of ornaments, including circular or spiral earrings, wire necklaces, moon-shaped pendants, and intricate, segmented copper diadems, have been unearthed. These opulent items underscore the high status of women in these societies. Additionally, detailed microscopic analyses of the copper ornaments within these graves have provided valuable insights into organic materials associated with the clothing of the deceased and the assembly of decorations. This comprehensive examination not only contributes to a nuanced understanding of the intricate burial practices but also illuminates previously unexplored dimensions of the social and cultural dynamics of Late Neolithic societies.

13 STATUS AND IDENTITY DURING THE CHALCOLITHIC OF INNER IBERIA: THE STONE BEADS FROM THE TOMBS OF HUMANEJOS (MADRID, SPAIN)

Paulos-Bravo, Rodrigo (Complutense University of Madrid) - Garrido-Pena, Rafael (Universidad Autónoma de Madrid) - Herrero-Corral, Ana Mercedes (Austrian Archaeological Institute, Austrian Academy of Sciences) - Flores Fernández, Raúl (Independent scholar, Madrid, Spain)

During the first half of the 3rd millennium BC, a series of changes took place in the populations of the interior of Iberia that can be traced through the archaeological record, such as an increase of grave goods, the first appearance of copper tools/weapons or the use of elements of personal adornment made on exotic raw materials (variscite). At the Humanejos site (Parla, Madrid, Spain), 160 stone beads were discovered in the graves of just seven individuals, dating between 2800 and 2500 BC. Given their quality, singularity and scarcity they would have a significant symbolic meaning and role in the construction of social status, gender and personal identities during their lifetime and also in the burial ceremonies. To understand their value in those societies, it is crucial to identify whether these ornaments were specifically manufactured for the grave or instead they were part of the everyday image of their bodies.

Most of the raw materials used in their fabric are exotic, coming from distant places, hundreds of kilometers away. The mobility and exchange of these exotic goods reveals intense network of inter-regional contacts that reached its peak during the Bell Beaker period. However, at Humanejos, the use of rock beads is limited to the first half of the 3rd millennium BC, with a clear connection with the first copper elements documented in the region.

14 A NEW STYLE OF CLOTHING AND ORNAMENT? SOME EARLY BRONZE AGE BURIAL GIFTS FROM WEST ANATOLIA

Oguzhanoglu, Umay (Pamukkale University)

The Anatolian Early Bronze Age is characterized by major transformations regarding the process towards centralization and urbanization. Archaeological records this transformation was related to a newly emerging and increasingly powerful elite class. The elite in question which usually live within reinforced citadels and some central buildings, manifest themselves through various practices such as owning prestige objects and practicing special rituals -including special drinking ceremonies-. The long-distance communication networks established by these elites carry prestige objects as well as raw materials, products, and technology. Undoubtedly, new clothing and adornment items - either locally designed or imitated after long-distance interactions- must have emerged as a part of looking like a real "elite".

This presentation aims to examine some West Anatolian burial gifts, some of which are considered to have become widespread as a result of interregional trade, including metal spirals, pins (mostly clothespins), and some personal weapons as signs of a new clothing/ornament style that emerged among the elite. Some recently excavated tombs in Western Anatolia, yielded pins and spirals made of gold and silver as well as daggers made of copper/copper alloys which have been in use since the beginning of the Early Bronze Age (EBA I/ca. 3200 BC). In the following period (EBA II), daggers, razors, spirals, pins, and toggle pins continue as a collection of personal belongings inside the graves. This situation should be associated with the fact that the elites, who began to differentiate themselves at the beginning of the EBA, adopted a new understanding of clothing and added some materials and styles that they learned from long-distance relationships to this new style of adornment. They might also have converted some personal/daily clothing materials of neighboring cultures into prestige objects.

15 BEADS IN DIBBĀ AL-BAYAH: EXPLORING PERSONAL ORNAMENT AND IDENTITY CONSTRUCTION ACROSS THE LATE BRONZE AGE - EARLY IRON AGE TRANSITION

Larosa, Nunzia (University of New England, Australia) - Genchi, Francesco (University La Sapienza of Rome)

Beads are one of the most frequent finds in an archaeological excavation after ceramics. In the last decades the analysis of their internal variability, modes of production, uses and contextual associations has been used to track changes in group identity over time, with raw materials acting as a proxy for long range trade and cross-cultural interactions. Yet, the study of personal adornment still plays a secondary role in the reconstruction of the human historical narrative, especially in Southeastern Arabia (United Arab Emirates and Sultanate of Oman), where beads themselves are often overlooked or relegated to the status of minor finds.

More than twelve thousand beads have been recovered from the Late Bronze to Iron Age funerary context of Dibbā al-Bayah in Oman. This research explores the archaeological significance of beads as an indicator of cultural variability and identity construction among the Late Bronze Age and Iron Age communities of northern Oman (ca. 1600-300 BC), based on a series of specific stylistic, technological and morphometric features. A systematic and integrated methodological approach is complemented by provenance analysis (LA-ICMPS) to better understand the social (i.e. differences in status, interregional connectivity, and social identity) and economic (i.e. differential access to wealth/luxury items, differences in trade networks) characteristics of the societies in Southeastern Arabia during this period of rapid and major social transformation.

16 FASHIONING WOMEN IN KERMA - BODY ORNAMENTATION AND CLOTHING IN THE EASTERN CEMETERY (2100 - 1450 BCE, SUDAN)

Yvanez, Elsa (University of Copenhagen) - Skinner, Lucy (University of Copenhagen)

Located in Upper Nubia, in modern Sudan, the Bronze Age site of Kerma developed as the economic, religious, and cultural epicenter of the Kushite kingdom, between c. 2100 BCE and 1450 BCE. Before falling under Pharaonic rule, the town housed a stratified population, whose elite buried their dead in chamber graves under large tumuli. Recurring material assemblages and burial characteristics indicate the codification of funerary rituals, well known from the early 20th Century extensive excavations of the Eastern Cemetery, led by Georges Reisner, as well as more recent work carried out by Charles Bonnet and Matthieu Honegger. Excavations have uncovered a wealth of organic remains from garments (animal skin and textiles) and personal ornaments, and documented the frequent practice of interring other humans in the burial to accompany the primary body or tomb owner. This was especially the case in the Classic Kerma period, where large royal tumuli were outfitted with 'sacrificial corridors'. Today stored at the Boston Museum of Fine Arts, the archives and artefacts recovered by Reisner show that some of the female 'accompanying-dead' were prepared for burial dressed and adorned with similar items - including leather skirts and head adornments, as well as other body ornaments. This presentation will build a picture of selected funerary assemblages related to female accompanying-dead, and question how clothing and body ornaments help us to better define their identities. By comparing these

findings to the assemblages associated with other female burials (the primary deceased), we will attempt to reconsider questions of gender, social roles and status at Kerma.

17 THE LEG RINGS OF THE KOBAN CULTURE IN THE CENTRAL CAUCASUS

Kotova, Nadezhda (Institute of Archaeology Ukrainian Academy of Sciences, Kyiv) - Makhortykh, Sergey (Institute of Archaeology Ukrainian Academy of Sciences, Kyiv)

In the 9th-8th centuries BC., the Koban Culture of the mountainous Central Caucasus reached its highest development, which is also reflected in the spread of numerous and varied women's ornaments. Sociological and anthropological studies of personal adornments highlight the importance of this category of material culture in marking life stages and expressing gender and age-specific characteristics. Our paper examines the role of gendered adornment in the Koban Culture in the Late Bronze - Early Iron Age Central Caucasus, based on evidence for bronze leg-rings from burial contexts in the 9th-7th centuries BC. Tombs in the Koban and Tli cemeteries indicate that pairs of anklets (both decorated and undecorated) were a highly visual symbol associated with the body and they were worn primarily by high-status women. Leg rings often appear in combination with other personal ornaments, such as bronze temple and zoomorphic pendants, belts, arm and finger rings, bead strings, which will also be subjected to our analysis, as they allow us to determine the chronology of the funerary assemblages under consideration. The custom of decorating the legs with anklets has no local origin in the Koban Culture, so the question of its appearance here is examined in the light of cultural interrelations with various regions of Western Asia where this tradition has its oldest roots.

18 PERSONAL AMULETS FROM THE LATE SCYTHIAN NECROPOLIS CHERVONY MAYAK

Dzneladze, Olena (Institute of Archaeology of NASU)

The Late Scythian hill-fort and necropolis Chervony Mayak are located on the right bank of Dnipro in Kherson district. In total 177 burial structures were excavated at the Chervony Mayak necropolis presented by individual and collective burials, as well as several cenotaphs.

Various amulets occupy a separate place of grave goods in the funeral rite of the Late Scythians. They were found on the neck and chest of the buried as part of necklaces or as separate pendants, and were also found on the belt and hips as part of filling of leather purses. Mostly amulets accompanied the burials of children and women, less often men. Beads amulets were also found on horse harness.

In total, 160 various amulets were found at Chervony Mayak among the personal grave goods of the buried. Amulets found in Chervony Mayak could be classified into following categories: the Egyptian faience, bucket-shaped pendants, bells, openwork pendants, knobby rings, eye beads, holed coins, animal bones, fangs, claws, cowrie shells and holey stones – “Chicken Gods”.

Amulets in the Late Scythian culture were associated with ideas and beliefs about the evil eye, jinx, spoiling etc. Late Scythians used these items as apotropaic amulets and charms for protection themselves from evil forces.

According to usage of such amulets in the Roman and barbarian societies, it is possible to assume that the Late Scythians also believed in power of amulets for different aims: protection of damage, the evil eye, as well as attracting good luck, fortune and fertility.

Young women and children were the main owners of such amulets as the most vulnerable groups of the Late Scythian society.

19 SKIN ORNAMENTS: EXPLORING IDENTITIES AND MATERIALITY THROUGH BODY MODIFICATION IN PAZYRYK

Pereira Gómez, Mar (EcoPast GI-1553; University of Santiago de Compostela)

Personal ornaments often transcend their mere aesthetic function to become deeply rooted manifestations of identity and culture. Among the oldest forms of ornamentation are body modifications, which can manifest through temporary practices such as painting, or through permanent alterations like tattooing or scarification. For many cultural groups, these modifications not only represent the transition from the natural to the social, but also affirm the full humanity of an individual.

Considering tattooing as an object, we venture to explore beyond the physical designs etched into the skin. We delve into a deeper analysis of the societies that practice them, recognizing that these bodily markers transcend physical boundaries to reflect complex social, cosmological, and ritual interactions within a community.

Throughout history, all cultures have employed some form of body art as an integral part of their cultural expression. Focusing on the case of the human remains discovered in Pazyryk, tattoos stand out as one of the most distinctive ornaments of this culture. They impress not only for their technical and artistic quality but also represent a deeply ingrained form of cultural and social expression in that ancient society.

With this study, our aim is twofold: on one hand, to deepen our understanding of the techniques and processes used to create these body art pieces. On the other hand, we seek to better comprehend these societies through their artistic and cultural expressions.

20 UNVEILING IDENTITY DYNAMICS IN THE SILVER 'ACORN' EARRINGS FROM TALL AL-'UMAYRI, JORDAN

Verduci, Josephine (University of Melbourne)

Within the corpus of Iron Age metal jewellery from the Near East is a unique pair of Late Iron Age earrings. These earrings, distinguished by their acorn-shaped pendants, have no direct parallel. Nevertheless, they are part of an adornment tradition that circulated across the Mediterranean during the period of Phoenician expansion from the 7th century BCE. This work aims to examine this specific category of material culture in light of the growing body of research on ancient Near Eastern jewellery through the lens of phenomenological theories of embodiment. In addition, I apply a symbolic interaction framework to examine the role of adornment in identity construction and memory formation. The person who wore these earrings almost certainly used them to construct and broadcast their elite identity by employing a valuable form of adornment with introduced cultural elements. Simultaneously, the pendants' acorn imagery may have actively linked social identity, particularly female identity, to fertility and sustenance through their mnemonic attributes. Thus, this study seeks to reveal how individuals employed these objects to convey personal intentions, denote social status, and communicate ritual ideologies, thereby reflecting the multi-faceted dimensions of identity expression.

21 BEADED IDENTITIES: THE CONSTRUCTIVE POWERS OF JEWELLERY IN DANISH VIKING AGE BURIALS

Thompson, Emma (University of Leicester)

Within Viking Age archaeology, we are beginning to explore the concept of “living objects” in graves. This proposes that artefacts could be charismatic and animated, with social biographies of their own, and experience their own death and burial. The discourse, thus far, has mostly concerned objects conventionally associated with men, particularly swords. There is value to this, as there is significant burial and literary evidence to support the importance and impact of swords, but we are missing critical nuance about the items typically associated with women, such as brooches and beads, further relegating these objects to passivity. In the medieval literary evidence, jewellery could have personal names, much as weapons could. Consequently, we must also examine the transformative powers of apparel, both in their creation and (re)use. Just as we make jewellery, it makes us.

Interpretations of grave goods are often contentious, particularly when considering the “true” identity of the deceased. Burials are famously staged events where mourners choose how and where the deceased is buried and, most relevantly, what to include within the grave. To this end, these contexts contain complex intersections of real and idealised identities, influenced by what the respective society deemed acceptable. Despite their caveats, graves offer a unique and valuable avenue to explore individual and collective identity constructions. Historically, there have been tendencies to treat grave goods as passive objects: transmitters of meaning or conduits for metaphor. However, we must assess the role objects play in adorning, constructing, and idealising bodies in life and death.

This paper will examine 95 graves containing jewellery from a larger dataset to explore how these objects actively construct the mortuary identity of the deceased, in tandem with other burial characteristics. This includes body-object and object-object negotiations, as well as further contextual evaluations.

22 OBJECTS OF IDENTITY? THE ROLE OF GRAVE GOODS IN VIKING AGE FUNERARY PRACTICES

Norstein, Frida Espolin (Department of Archaeology and Classical Studies, Stockholm University)

Within Viking Age archaeology grave goods have been central for the discussion of identities. Different types of artefacts have been regarded as especially significant for signalling specific aspects of identities, particularly related to gender, status, and in some areas also ethnicity. Partly due to the nature of the source material, which consists of often very poorly recorded graves, little attention has generally been paid to variations in how they were used and how they relate to the dead body. Are they likely to have been personal belongings? At what stage did they become part of the funerary rituals, and how visible would they have been? This paper examines the role of different types of grave goods, such as jewellery and weapons, but also more mundane artefacts like whetstones in funerary practices, in order to assess the relationship between the artefact and the deceased body, and what this can tell us about the role of different types of grave goods in signalling and creating personhood and identities both before and after death.

23 MEDIEVAL PILGRIM BADGES FOUND IN NORWAY – PILGRIMAGE TO ITALIAN SHRINES FROM THE FRINGES OF THE CATHOLIC SOCIETY

Simonsen, Margrete (Museum of Cultural History)

In this paper I will focus on the finds of pilgrim badges in Norway, with provenance from Italian shrines as Rome, Lucca and Bari. A recent find of a pilgrim badge depicting St. Nicolaus, is a starting point. Apart from this find, there are all together six finds from Italian shrines. These are small metal images of the saints with loops or holes for fastening, used to fasten on clothes, hat or bag. Used as signs for pilgrims as a social group, for personal adornment and symbolic content. Their finds context varies, from stray finds to other finds recovered by excavations in churches, monasteries and medieval towns. I will further discuss what the pilgrim badges represent and their meaning in Medieval society. Also, the pilgrimage, different pilgrims and motives, the secular and the penitential pilgrims. I will further refer to the historical records and what they tell about pilgrimage to these shrines. Finally, I will discuss connections and cultural ties between Rome and the fringes of the Medieval Catholic community, such as Norway.

24 ADORNED IN SILK AND SILVER: TABLET-WOVEN BANDS IN HIGH-STATUS FEMALE DRESS OF THE LATE VIKING AGE

Rimstad, Charlotte (National Museum of Denmark)

In the Late Viking Age Scandinavia (900-1050 AD) a change took place in the dress habit of high-status females. While the female clothing of first half of the Viking Age was closely connected to the oval brooches that carried the suspended dress, a dress without brooches was used in the late part of the period. From several female graves in Jutland, such as Hørning, Hvilehøj and Fyrkat, evidence of precious tablet-woven bands of silk, silver and gold threads have been found, both used as decoration on garment edges and on top of fur garments. The tablet-woven bands were produced of imported materials and their quality not only expresses the high skills of the artisans who made them but also underline the high status of the females wearing them. They are clearly symbols of power and prestige. The project “Female dress of the Late Viking age” investigates the bands and garments in order to see why this change of dress happened, how the new dress type was constructed and what role the tablet-woven bands played. Aspects of production and decoration are addressed through fibre and dye analyses and comparative sources included. The project thus seeks to answer questions on production, inspiration, import, status and identity in the later part of the Viking Age. In this paper, the initial results of the project are presented.

25 JEWELS, PIGMENTS AND COSMETICS: AN ENQUIRY INTO THE BUDDHIST CLAY SCULPTURE IN AFGHANISTAN (4TH/5TH -8TH CENTURY)

Forgione, Giulia (University of Naples “L’Orientale”; Italian Archaeological Mission in Afghanistan)

The subject of this presentation is the Afghan Buddhist sculpture in clay and stucco, a tradition which reached its apex from the 4th/5th century to the 8th century CE.

We still have insufficient knowledge about the material and technical aspects of this artistic production, as well as about its iconographic codes and meanings. This is partly due to the fact that there is still limited research on the cultural background of this tradition, but also because the fragility of the materials is responsible for the poor preservation of the artworks. Despite the difficulties, however, new and more inclusive studies, which take into account all fragments of any size, even the most minute ones, are now significantly expanding our knowledge.

The fundamental role played by ornaments and jewels in the characterization of both images and their settings is well-known. What is more, recent excavations at Mes Aynak (Logar province) have brought to light real jewellery that shows the same forms documented in plastic art in important archaeological sites such as Tapa Sardar (Ghazni area).

Colour must have also played a significant part, especially when it reflects a non-naturalistic use, which in turn suggests some sort of symbolic value. However, the pigments used to paint the sculptures were often obtained from the same precious materials (such as gems and gold, or materials that resemble them) that were used to produce jewels. Viewed from this perspective, pigments can be considered as “precious substances” that adorned the figures.

After a brief overview combining jewellery, precious substances and pigments, the presentation will focus on how the choice of colours may not only conceal a high symbolic meaning but may also reflect commonly accepted beauty standards and customs, such as the use of specific pigments for specific body parts.

26 BODY DECORATIONS IN THE ANDES, AN EXAMPLE OF BODY PAINTING AND TATTOOING IN THE CHANCAY CULTURE

Bak, Judyta (Jagiellonian University)

In the cultures of the pre-Hispanic Andean region, body painting and tattooing were widely known customs, attested to by numerous empirical evidences. The long tradition of this practice is assessed by the rich and diverse archaeolog-

ical material, including –but not limited to– pottery representations of people bearing tattoos and mummified human remains whose bodies are covered with decorations. A perfect example of a culture where evidence of practicing this art of body decoration has been preserved to this day is the Chancay culture (1200-1400 AD), from the central coast of nowadays Peru. It is worth noting that the perception of painting and tattooing in the aesthetic dimension is the domain of modern times, while in archaic societies it is a procedure present in several connections within an integrated socio-cultural system. The main purpose of the speech is to present the evidence, preliminary analyses, and plausible interpretations of tattooing/body painting practice in the Chancay culture.

1107 MANIPULATING SENSES AND STAGING THE INCONCEIVABLE. DISCOVERING THE EMBODIED PAST BY PHENOMENOLOGICAL EXPLORATIONS AND OTHER METHODS

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Kranig, Friederike (Römisch-Germanische Kommission (Frankfurt am Main); Georg-August-Universität Göttingen, Abt. Christliche Archäologie und Byzantinische Kunstgeschichte) - Lorenzon, Marta (University of Helsinki) - Gheorghide, Paula (University of Helsinki) - Kerk, Lukas (Universität Münster, Abteilung für Ur- und Frühgeschichtliche Archäologie) - Sager, Tia (University of Toronto)

Session format: Regular session

Despite their individual and subjective nature, human sensory experiences are always a social construct, dependent on society, culture, or ethnicity. Through all ages, senses were and are utilized, deliberately stimulated and manipulated through purposeful staging. In both sacred and mundane contexts, the impact of architecture, sound, light, smell or haptics can help to engage with a new situation. Staging manipulates the sensorium and the subconscious of the receiver in order to make something imaginary bodily experienceable and thus to appear real.

Recent scholarship on perception, human behaviour, agency, and movement is being foregrounded in both ethnoarchaeological and architectural studies with a focus on the multi-sensoriality of material culture. Especially acoustics is something intangible that does not manifest itself within an object, but only in ongoing time. Of course, such fluid objects are difficult to research due to their ephemeral nature. For precisely this reason, however, we want to find new ways of thinking about senses and reconstructing the past in the archaeological practice. Once we get over the more deterministic tendencies, how can we combine phenomenological approaches with scientific data? How can we recreate sensory experiences through digital or analogue technologies? Can we conceive of an integrated methodology for experimental archaeology?

This session aims to unite diverse strands of research exploring novel avenues and directions in sensory and experimental archaeology. We invite presentations that explore different phenomenological and methodological approaches to the study of the chaîne opératoire of staging and perception, technical variability, investigations into buildings, monuments and roadways outside traditional approaches, and cutting-edge tools that contribute to the creation of new methodologies for experimental and ethnoarchaeological work. We encourage papers from a wide range of archaeological and nonarchaeological discipline, which are rooted in multidisciplinary research contributing to the evolution of sensory archaeology as a discipline.

ABSTRACTS

1 MANIPULATING SENSES AND STAGING THE INCONCEIVABLE: AN INTRODUCTION TO THE ONGOING SEARCH FOR NEW METHODOLOGIES

Kerk, Lukas (Abteilung für Ur- und Frühgeschichtliche Archäologie, Universität Münster) - Kranig, Friederike (Römisch-Germanische Kommission (Frankfurt am Main); Georg-August-Universität Göttingen, Abt. Christliche Archäologie und Byzantinische Kunstgeschichte) - Lorenzon, Marta (University of Helsinki) - Gheorghide, Paula (University of Helsinki) - Sager, Tia (University of Toronto)

Although intangible cultural heritage is becoming increasingly important in archaeological research, and although the senses have been of immense significance for everyday life at all times and in all societies, their archaeological investigation is still somewhat incomplete. The term “archaeology of the senses” imprecisely summarises the various, albeit interrelated, sub-areas. Whereas archaeoacoustics, for example, initially focussed mainly on the acoustic measurement of archaeological spaces, it now describes a growing field in which the audible is thought alongside the visible and the ephemeral accompanies the permanent. To research the sensescape of ancient cultures, approaches and methods from different disciplines are increasingly being integrated into the archaeological field. However, this transfer of methods not only adapts the theoretical approach, but often also its limitations and the resulting problems. In the theoretical discourse, this leads to antithetical pairs such as phenomenological and constructivist approaches or quantitative and qualitative field studies, which appear almost irreconcilable to each other.

In our introduction, we would like to consider different research directions that might sometimes appear contradictory at first glance and merge them into new approaches. This results in a methodological diversity, the applicability of which needs to be examined regarding the respective question. Which theory is behind the chaîne opératoire and how can it be applied to our research interest? Which opportunities does phenomenology offer and what is described by the concept of staging? How can quantitative and qualitative field studies or the study of the material and immaterial aspects be brought together? These and many other questions will be explored in our session, for establishing an understanding of the intangible cultural heritage based on sensory perception as a part of archaeological research.

2 PERFORMATIVE PILGRIMAGE OR DIVINE CHARITY? EXPLORING THE TRANSFORMATION OF BODILY IDENTITY AT ROMAN SANCTUARIES

Vierula, Sofia (University of Helsinki)

The classical interpretation proposes that Ancient Romans understood illness and disability as divine punishments, and healing was considered a divine intervention. However, critical examination of healing at Roman sanctuaries suggests that Roman pilgrims had agency on their bodily identities; a crucial aspect of the pilgrimage was the transformation of the identity of the body, the healing process. The pilgrims participated in bodily rituals and performances that changed their perception of the world and how others perceived them. Thank-offerings were left afterwards to commemorate these transformations and the changes in the pilgrims' perception, as well as to influence new pilgrims' perception of the divine presence.

Roman sanctuaries facilitated immobile deities that had deep connections to their locations. Thus, pilgrims had to travel to them. To connect with the deities, the pilgrims engaged in bodily rituals such as fasting and washing that transformed their bodily identity. One approach to understanding this process of healing in ritual space is the idea of performative body by Judith Butler (1990). This concept is applicable to Roman sanctuaries; for Romans, the identity of the body was performative and transformative. For example, incubation and bathing can be interpreted as performances with an intention to transform the body, and regulations such as uniform clothing existed to create the pilgrim identity.

Following Aldred (2021), movement transforms the bodily identity, and boundaries shape the development of this mobility. At Roman sanctuaries, these boundaries are set by the landscape of the ritual space. The sanctuary imposed natural order on the pilgrims' disorganised bodies, subjecting them to healing. As sanctuaries have innate liminality between the worldly and the otherworldly, they facilitate a connection to the divine that was achieved through ritual and performance, and that transformed the pilgrims' bodily identities. The perceived divinity existed in this transformation and in pilgrims' bodily agency.

3 SEMANTICS OF SMELL: EXAMINING AN IRON AGE LIMESTONE INCENSE BURNER FROM TELL AL-ASSARA, NORTHERN JORDAN

Lahelma, Antti (Unioninkatu 38F 00014 Helsingin yliopisto Finland)

Tell Al-Assara is a recently discovered fortified hilltop site near Irbid in Northern Jordan, preliminarily dated from the Late Bronze Age to the Hellenistic period (ca. 1500-63 BCE). One of the more unusual finds from the 2022 excavation season at the site, conducted by a joint Finnish-Jordanian team, consisted of a small, four-legged incense burner made of limestone, found in what was most probably a domestic context. The item found at Tell Al-Assara can be typologically dated to the Iron Age, possibly the Persian period (586-332 BCE). The artefact type as such is well known, as large numbers of roughly similar incense burners have been throughout the Ancient Near East, but its nature and function are contested.

In earlier research, incense burners of this type have been considered mainly from the point of view of religious history, as material evidence of a 'foreign cult' spreading throughout the Levant, but given their humble appearance and often clearly domestic find contexts, their function as 'cult objects' has more recently been called into question. The use of incense in an Iron Age tell is likely to have been a multi-faceted phenomenon, with both religious, domestic, apotropaic, hygienic and deodorizing dimensions, and these did not have to be mutually exclusive. A factor hindering our understanding of the nature of these artefacts is the relative paucity of natural-scientific analyses on the type of materials burned. In this paper, the results of chemical analysis from the contents of the Tell Al-Assara artefact and other contemporary finds from the region are discussed, and textual sources are explored with view to the 'meanings' associated with particular smells in Iron Age Levant. The aim is to better understand the odoriferous environment of the tell and the role that incense and smells played in the daily life of its inhabitants.

4 DOING LANDSCAPE: SENSORIAL AND ARTISTIC APPROACHES TO DONKALNIS AND SPIGINAS MESOLITHIC-NEOLITHIC RITUAL SITES IN WESTERN LITHUANIA

Ahola, Marja (University of Oulu; University of Helsinki) - Lassila, Katri (Aalto University) - Mannermaa, Kristiina (University of Helsinki)

During the Mesolithic and Neolithic periods, foragers residing in the Eastern Baltic, Scandinavia, and Fennoscandia buried some of their dead on lake islands or other coastal sites. Drawing from ethnographic accounts, these locations are often interpreted as 'deathscapes,' transitional areas where water separates the lands of the dead and the living. In this presentation, we adopt a more relational perspective on these sites and propose that a particular combination of spatial perception of landscape and the dynamic nature of coastal sites may have contributed to the personality and social agency of these places, resulting in their use as places for ritual activity.

To delve deeper into this hypothesis, we visited Mesolithic-Neolithic forager burial sites of Donkalnis and Spiginas (Western Lithuania) in the spring of 2023, investigating whether there was something about these places that could have set them apart from their surroundings during their period of use. Employing a phenomenology-based methodology, we approached and perceived the sites from several directions, documenting our sensory encounters with the landscape through notes and drawings. To incorporate an 'outsider's perspective', the archaeological investigation was complemented by artistic research conducted by a professional photographer capturing imagery and video art at the sites, along with interviews of the archaeologist responsible for the discovery and excavation of both locations.

As a result, we propose that the ancient foragers of this region interred human remains at Spiginas and Donkalnis to be part of the places themselves. Like other intentional depositional acts, this may have been undertaken to mark the location or to communicate with the surrounding world. Furthermore, we concluded that the application of artistic practices – whether through camera lens or drawing – proved beneficial to our analysis by slowing us down and creating 'mementos of moments' that we could reflect upon after the fieldwork.

5 SENSORY DIMENSIONS IN NEUROARCHAEOLOGY: EXPLORING MUDBRICK MANUFACTURING ACROSS THE MEDITERRANEAN

Lorenzon, Marta (University of Helsinki)

This contribution discusses sensory perception of earthen architecture combining neuroscience, phenomenology, and archaeology, specifically focusing on the manufacturing of earthen building materials and the experiencing of the built environment. The paper discusses the survey results of the multisensory experiences of both skilled and semi-skilled mudbrick manufacturers, drawing insights from experimental and ethnoarchaeologic fieldwork.

The analysis of the ethnographic data provides new evidence to increase our understanding of how individuals lived, experienced, and interacted with the built environment in their daily lives. It offers a detailed examination of multiple case studies in the Mediterranean, specifically in Crete and Egypt with cross comparisons with materiality from Minoan Crete and Graeco-Roman Egypt. Despite the predominant visual focus in archaeology, the argument posits that material culture, particularly earthen architecture, facilitated a multisensory encounter engaging all senses, transcending mere visual stimulation. This research contributes to a more holistic understanding of the lived experiences and sensory dimensions associated with earthen constructions in ancient contexts.

6 CROSSING THE THRESHOLD - EXPERIENCING TRANSITIONS. A NEOLITHIC PERSPECTIVE

Waszk, Benny (Johannes Gutenberg-Universität Mainz) - Kinzel, Moritz (Abteilung Istanbul des Deutschen Archäologischen Instituts)

The built environment of the early Neolithic of Southwest Asia was the first large scale laboratory of human – built space experiences; a game changer in the perception of space and human made sensescapes. A key to understand the importance of crossing borders and territories (as part of the Neolithic cosmos) is to study Neolithic doorways. In particular the monolithic portal stones found in the Urfa Region at sites like Göbekli Tepe offer a unique insight into the perception of transitions from one space to the other. Here all senses were activated and put in place; physically, visually, and metaphorically. Interestingly, there are several different concepts in place that show a skilful use of a set of options to create certain settings according to the needs of the user and possible narratives the builder wanted to convene. The contribution will present the results of a study of Neolithic portal stones from Göbekli Tepe and beyond and discuss the impact of the "access" for the perception of the buildings now and in the past.

7 VEILED VISIONS: THE INFLUENCE OF CURTAINS ON RELIGIOUS PERCEPTION IN LATE ANTIQUE CHURCHES

Mairhanser, Corinna (Ludwig-Maximilians-Universität München)

Across cultures and epochs, the gaze holds a prominent role in the realm of religion, allowing the viewer to interpret various forms of artistic expression, religious spheres, and abstract concepts. When visual perception is veiled by curtains, as is often the case in Late Antique and Byzantine churches, various staging effects occur. How did this make divinity and religious concepts tangible within churches, despite their abstract nature? What impact did the curtains have on the visitors' religious experience and visual perception? How can these effects be made understandable today?

Pictorial evidence suggests that curtains often operated at thresholds. They were arranged in various layers around the liturgical centre of the church, the Holy of Holies, in which the Christian belief manifested itself. Visitors moved systematically through these different spheres as they entered the church without being able to experience them in their entirety. In the process of perception, these textiles evoked culturally standardised imaginings without allowing for verification by looking behind the curtain. From a cognitive and psychological perspective, this *velatio* is the most intriguing function of curtains since the imagination of the beholder tries to visualise what is concealed. The activated *phantasia* surpasses the threshold of the concealed, creating its own reality, and fostering the illusion of deeper insight into the church's sacredness. The desire to unveil the supposed mystery of faith is symptomatic of the perception of veils and curtains in churches, but it is only one aspect of their function as media of presentation, highlighting and marking transitions. Through their dynamic and performative qualities, curtains captivate human attention, activate imagination, and heighten expectations.

This paper raises questions and provides new insights into how curtains elevate meaningful religious things, create sacred spheres, and define holiness by influencing human perception – effectively positioning the potentially visible “behind the veil”.

8 THINKING THROUGH THINGS: SURROGATE OBJECTS IN EIGHTH-CENTURY NORTHUMBRIAN CHRISTIANITY

Walsh, Ciarán (Queen's University Belfast)

In recent years research into the relationship between material culture and the mind has been revolutionised by developments in the philosophical tradition of speculative realism. This approach has allowed philosophers to circumvent the epistemological problems presented by the Kantian dichotomy between noumena (objects in the world) and phenomena (mental representations) by redefining the “mind”. In this tradition, the mind is not treated as something abstract that exists entirely within the brain, but as an emergent product that comes into being via the interactions of three individual agents: the brain, the body and the material environment. Applying these ideas to the field of archaeology, Lambros Malafouris's *How Things Shape the Mind* (2013) introduced the concept of “surrogacy”. “Surrogacy” is the quality that an object exhibits when it becomes part of human consciousness: not as an “aid” to thought, but as an essential component of a mental process that could not exist without it.

My presentation will employ the concept of “surrogacy” to analyse two objects from eighth-century Northumbria in order to suggest how these objects functioned as parts of the early-medieval mind. The two objects of my analysis will be the Ruthwell Cross (a 5-metre-tall stone cross, decorated with religious carvings and runic inscriptions of Old-English poetry) and St Cuthbert's Coffin (the elaborately decorated container in which the relics of St Cuthbert were transported around Northumbria). By closely observing features of how these objects were designed – as well as the historical records in which they are mentioned – I will suggest how these objects affected both the sensory perceptions of eighth-century Northumbrian Christians, and their interpretations of those perceptions. In medieval Northumbria, these objects were psychological necessities, giving medieval Christians the necessary material scaffolding to allow them to believe in a religious system which would otherwise appear inconsistent with reality.

9 THE SOUNDSCAPE OF LATE ANTIQUITY BETWEEN ETHNOLOGY AND (COMMUNITY) ARCHAEOLOGY. ACOUSTIC STAGING ON THE TUR ABDIN

Kranig, Friederike (Römisch-Germanische Kommission (Frankfurt am Main))

An investigation of complex soundscapes of ancient times and their contextualization in past and present communities requires new approaches that not only reconstruct sounds and acoustics, but also permit an understanding of their social-, cultural- and identityforming significance. Capturing the versatility of a region characterized by cultural density such as Tur Abdin is made easier or even possible, if the regional communities are included. Beyond the tried and tested approaches from ethnomusicology and archaeology and with the aid of community archaeology it is possible to make the immaterial object ‘sound’ and its effects on the individual and the community tangible and ultimately describable.

The Tur Abdin is located east of the Cilician Gate, which marks the entrance to the Mediterranean region. It describes the area ‘in front of it’ and thus a permanent transit area characterized by historically evolved transculturality. Part of this Mediterranean-West Asian ‘mixed culture’, as a coexistence of different linguistic, religious and ultimately ethnic identity groups, is, among others, the culturally and historically conditioned understanding of sounds, the musical experience. Being influenced by such culturally specific experiences, it is difficult for the western or ‘occidental’ ear to hear through the subtleties within this multilayered world of sound. Only through the exchange with the ‘initiate’, mutual understanding can be improved. Only in this way is it possible to understand a culture and its cultural history from the inside and to generate new possibilities of interpretation.

This play of thoughts focuses on the medium music as an intraculturally unifying, interculturally connecting element using the example of West-Syrian Orthodox Christians at the Tur Abdin. My considerations are based on my ongoing ethnomusicological and -archaeological field study on the possibilities of acoustic staging in late antiquity using the example of the monasteries of Deyrul Zafaran, Mor Gabriel and Mor Augin.

1108 ARCHAEOLOGY, TEXT, NARRATIVE, AND THE USABLE PAST IN GLOBAL PERSPECTIVE

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Ó Riagáin, Russell (University College Dublin) - Nol, Hagit (Goethe Universität, Frankfurt-am-Main)

Session format: Regular session

The concept of the/a “usable past” was coined by Van Wyck Brooks in 1918 in an attempt to retrospectively bind together disparate cultural elements in the USA. The instrumentalising of the past to shape collective memory is a feature of all human collectivities. Salient examples of this in the politics of the present and the past are to be found in the use of the shared-but-exclusive heritage of perceived golden ages from around the globe—e.g., the Rashidun Caliphate, Roman Empire, Gupta Empire, Tawantinsuyu, Mali Empire or Tang era, among many other points in space and time—to justify contemporary political systems, social stratification and inter-polity relations. However, it would be difficult to argue that the deployment of a usable past by established social groups this is ever totalising, with individuals and groups having complex relationships with the past and narratives associated with it.

This session seeks to take stock of the research being done across the globe on these issues, both in the present and the use of the past in the past. Papers are encouraged in relation to both case-studies where textual and archaeological evidence intersect and contradict, and on areas for which documentary narratives do not survive. Studies treating these processes outside Europe are particularly encouraged, as are comparative treatments of the problematic. Research questions that could be posed include—but are not limited to—why usable pasts are so often linked to military highpoints; the use of the past by groups writing against one another in narrative complexes; gatekeeping and selectivity and the past; the removal of the past in colonial relations; archaeology shaping and being shaped by narrative; and on the past as a socio-political and cultural resource more widely.

ABSTRACTS

1 SAXO AND SNORRI AS ANTIQUARIANS AND AUTHORS? BUILDING USABLE PASTS THROUGH ARCHAEOLOGY IN MEDIEVAL DENMARK AND ICELAND

Ó Riagáin, Russell (University College Dublin)

The descriptions of funerary activity in the writings of both Saxo Grammaticus (died c. 1220 CE) and Snorri Sturluson (died 1241 CE), active mainly in Iceland and Denmark respectively, have been particularly influential in modern-day scholarly discussions of funerary practices in the period c. 400–1100 CE in northern Europe and the North Atlantic. This paper seeks to flip this on its head by examining where and how these descriptions might have come from. Firstly, the content of Saxo and Snorri's narratives of funerary activity, laws and traditions will be abstracted and outlined, and broadly compared against the archaeological evidence. Secondly, the paper will explore the extent to which these writings were based on the authors' being present at the opening up of burial monuments, if not actually carrying out excavations. Relatedly, it will then consider the extent to which they may have gathered descriptions of archaeological remains being encountered by farmers, similar to the activities of nineteenth-century antiquarians. Finally, the paper will explore how pre-existing narratives of funerary activity, such as Virgil's *Aeneid*, shaped Saxo and Snorri's interpretation and narrative construction. Doing so will shed light on the interaction and cross-pollination between different disciplines within the study of the past in the past, and provide important context for similar studies across space and time by demonstrating how the evidence through which we interpret the past itself came about through the interaction of archaeology and narrative.

2 ARCHAEOLOGY AND NATIONALISM: BETWEEN JEWS AND ARABS

Katz, Hayah (Kinneret College on the Sea of Galilee)

The use of archaeological research for the construction of national narratives was often used by peoples and nations as a tool for the construction of identity. In this context, a comparison between the attitude of Arab archaeologists to the field versus that of Jewish archaeologists during the Mandate period raises a question of principle. While during this time (mostly the 1930s), the Jewish community promoted archaeological research and thereby used it for the purpose of building a national Zionist narrative, Arab archaeologists did not act in a similar way. I suggest that it was derived from different consciousness of the past. It seems that the Palestinian national movement saw itself as having a clear and obvious right to the land and did not need evidence from archaeological excavations. In contrast, the Jewish community was essentially an immigrant society. There was no continuity of settlement in Palestine for this society. Therefore, the Zionist movement's effort to inculcate the connection between the past and the present focused on archaeological finds unearthed from the depths of the earth, since only these could create a tangible expression of the past.

3 "ANCIENT TEMPLES COLLAPSED": ACTIVATING THE USABLE PAST TO REWRITE MEMORY IN THE URBAN SPACE OF ROME

Jacobson, Kearstin (University of Texas at Austin)

Created across Europe between the thirteenth and seventeenth centuries are more than a dozen extant visual representations in fresco, panel painting, manuscript illumination, and pen and chalk drawing depicting a Christian procession within an urban environment. At the center of each procession is a man wearing the papal tiara and often carrying a scepter or an icon of the Virgin; nearby a nimbed and winged figure observes the procession from atop a fortified structure while sheathing his sword. The religiously-charged occasion these artworks depict is not an historical event. Rather, it is a constructed pseudo-history based on an event that occurred twice at Rome, in 590 and 603, under the leadership of Pope Gregory I: the laetania septiformis ritual. Invented by Gregory, the laetania septiformis was a penitential procession performed simultaneously along seven routes within Rome as an ad hoc ritual prompted by civic calamity. It required participation across the city's entire urban landscape by all the Christian population for its salvific success. Though these processions never crossed into the northwest sector of the city where Hadrian's Mausoleum is situated, their dramatic climax was overwhelmingly identified by later sources as the archangel Michael's appearance to Gregory from the top of this pagan monument. Both visual and textual narratives insist on Michael's epiphany, raising questions of historicity and memory while emphasizing the power of the huge Mausoleum and providing a rationale for its Christianization. This paper examines a variety of sources, including Gregorian literature mentioning the laetaniae septiformes, visual and textual accounts of the Mausoleum, the debated dating of a small chapel dedicated to Michael on its summit, and the topography of the Ager Vaticanus from the ancient to late antique periods, to understand how and why the monument was incorporated into a mythologized version of the processions.

4 QIN SHI HUANG, THE LEGALIST (FA) THINKERS, AND THE CURRENT CHINESE NATIONALISM

Zaharia, Daniela (University of Bucharest)

Founding hero, disruptor of traditions, tyrant, and protector of the people, Qin Shi Huang (259–210 BC) has since ancient times been the subject of spectacular rewritings of history on a veritable interpretative roller coaster. Historically, he was treated, together with his legalist (fa) ministers, as an enemy of tradition by the prevailing Confucian ideology of the Empire from the Han to the Qing dynasties. Sima Qian (145–86 BC) used him as a pretext for conveying transparent criticism on the regime of the Han Emperor Wudi; in the 19th century, he and the legalist reformers inspired nationalist voices calling for China's resurgence as an imperial power; in the 1950s, he served as an anti-Confucian historical landmark in Mao's propaganda. Since the 1980s, the history of the First Emperor has been periodically revised according to the ideological shifts that have accompanied the reforms responsible for China's present global standing. The significance of Qin Shi Huang is heightened by the discovery of his famous tomb at Xi'an (1974), which has since proved to be an archaeological site of enormous complexity. The current dispute concerning the investigation of the funeral mausoleum coincides with a new re-evaluation of Shi Huangdi and the legalists as architects of the Empire. Our analysis will focus on the more recent reassessment of China's initial imperial rule. This will be done by considering the viewpoints of both official propaganda and popular culture. From "The Emperor and the Assassin" (Chen Kaige, 1998) to the recent screenings of Sun Haohui's novel "The Qin Empire" as a long-running television series (2009–2020), the portrayal of the First Emperor has experienced substantial transformation, associated with current stages of Chinese popular nationalism as well as the government's aspirations to establish the country as a global superpower.

5 DEFINING SPATIAL HERITAGE, IDENTITY, AND CONSERVATION TARGETS: EXAMPLES FROM SYNTHETIC LANDSCAPE BIOARCHAEOLOGY OF PRE-HISPANIC ANDEAN MIGRATION

Scaffidi, Beth (University of California, Merced)

The heart of the Central Andes pulses with human movement—immigration across borders, to urban centers, periodic or seasonal flows of workers, post-marital relocation, pilgrims and fiesta-goers—circulating through complex roads weaving together mountains, jungle, and sea. Claims to ancestral origins, lands, and the routes connecting them remain vital to narratives, rituals, and embodied identities of individuals, communities, and sociopolitical groups. With human movement so constrained by the vertical environment, modern roads and paths necessarily follow much of the Qhapaq Ñan (Inca roads), which was in turn superimposed on earlier Wari imperial roads. UNESCO recognizes both the tangible components of the Qhapaq Ñan (e.g., roads, structures, and petroglyphs) and intangible cosmologies related to sacred huaca and mountain apu worship as fundamental in shaping Andean cosmovision across a millennium throughout six countries. Even as tourists and local economies begin to benefit from Qhapaq Ñan tourism, aridification, glacial retreat, and coastal flooding intensified by climate change threaten the survival of traditional human movement spaces, beliefs, and practices.

Here, I explore how key findings from my bioarchaeological synthesis of pre-Hispanic human immigration patterns complement current understandings, meanings, and identity derived from the Qhapaq Ñan. I summarize human skeletal isotope meta-analysis methods and patterns before describing how I integrate the Qhapaq Ñan spatial network with landscape connectivity models, AMS and settlement pattern data to constrain isotopic baseline models to likely interaction zones. This narrows the differentiation of 'isotopically-local' and non-local individuals within a site and permits the identification of likely origin places and movement distances within zones. Isotopic similarity between groups along these key movement corridors reveals a nuanced history of human connection across these complex landscapes that can inform how stakeholder communities relate to each other and heritage management structures, and how they interpret, value, and conserve connective landscapes for future generations.

6 DISCONNECT BETWEEN TEXTUAL DESCRIPTIONS AND ARCHAEOLOGICAL AND GEOGRAPHICAL EVIDENCES AT AYODHYA

Jhunjhunwala, Bharat (Indian Institute of Management, Bangalore) - Randhawa, Manjit (Government Hospital, Patiala.) - Sood, Ankur (Advocate, Supreme Court of India)

Lord Rama makes a deep impression on the collective memory on the Hindus. Mainstream scholars and public believe that Rama lived at Ayodhya in the state of Uttar Pradesh around 2000 BCE. His rule is eulogized as a golden period of righteousness. The agitation of making a temple dedicated to Rama at this place forms the basis of revival of the Hindu religion.

The archaeological and geographical evidence, however, does not support the location of Ayodhya at this place. The earliest evidence of potsherds at the site is available only from 1600 BCE and the earliest structural habitations from 300 BCE. The descriptions of Ayodhya from the Valmiki Ramayana also do not match with the geography of the place. There is a disconnect between the textual narrative and the archaeological and geographical evidences. The ethnological evidence, however, is very strong here.

An alternative location for Ayodhya is believed to be at Ghuram in Patiala District of Punjab. Here, archaeological evidence is available from the Harappan period and it also matches with the geography described in the texts.

The paper makes a comparative examination of the archaeological, geographical, etymological and ethnographic evidences at the two locations. It describes how the more scientific location of Ayodhya in Punjab is suppressed to meet the political interests tied with the making of the temple at Ayodhya.

7 NINTH-CENTURY SAMARRA AND THE STRATIGRAPHY OF A MODERN NARRATIVE

Nol, Hagit (Goethe University Frankfurt)

One region in Iraq was excavated in the beginning of the 20th century. The 40 km-long cluster of sites was compared to the Arabic sources from the 9th to the 15th century CE and was identified as Samarra (Sāmarrā) or Surra Man Ra'ā. Samarra, according to historical accounts, was built by an Abbasid caliph in the mid-9th century in order to move his garrison and court from the capital then, Baghdad. As the story further goes, additional caliphs built various structures at the settlement until moving back to Baghdad at the end of the 9th century. The settlement apparently lasted much longer: the local mint (by the name Surra Man Ra'ā) has struck coins at least until the year 953 and geographers in the next centuries praise it. Only from the 13th and 14th century, do accounts describe the settlement as partially ruined. Nevertheless, 20th-century scholars – historians and archaeologists – picked one specific narrative, according to which the settlement was abandoned in 892. As a result, all the structures at the site, two identified as congregational mosques and many others as palaces, have been dated to the mid to late-9th century together with pottery and stucco from the site. These finds remain index fossils, used for dating parallels from other excavations and

surveys. Independent dating, however, provides different results. One inquiry of this talk revolves around the choice of Arab historians to glorify Samarra in a specific period, the mid-9th century. Another question is the reasons for modern historians to select this narrative. The third line of investigation regards the motivation of archaeologists to accept the narrative and the dates it implies even when these contradict the archaeological data.

1109 MESOLITHIC & NEOLITHIC EVOLUTIONARY TRAJECTORIES AT THE MEDITERRANEAN

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: García-Puchol, Oretó (Universitat de València) - Cortell-Nicolau, Alfredo (University of Cambridge) - Gallelo, Gianni (Universitat de València) - McClure, Sarah (University of California Santa Barbara) - Diez-Castillo, Agustín (Universitat de València)

Session format: Regular session

The last development of Mesolithic groups and the arrival of Neolithic newcomers triggered major changes in evolutionary population dynamics in the entire Mediterranean region, originating domino effects on cultural and socioecological trajectories at macro- and microlevel scales. The focus on narrative studies based on cultural sequences has been surpassed thanks to new structural epistemological perspectives that embrace systemic and agency approaches. This turning point reflects how human societies can be understood as complex systems that evolve in non-linear ways, changing by adapting to the effects of exogenous and endogenous causes. The great importance of pointing to high-resolution archaeological records based on accurate stratigraphic data and radiometric frameworks, that allow approaches at the scale of human events, and also the challenging interest of thinking on a population level, are fundamental in this new paradigm to approximate social relationship consequences considering local and regional dynamics. In this session, we adopt this view to embrace papers that take into account approaches aimed to highlight evolutionary trajectories in socio-ecological and cultural trends in Mesolithic and Neolithic Mediterranean societies, including regional or microregional views in diachronic perspectives. Research based on modelling the dynamics of culture change and socioecological trajectories (e. g. statistical modelling, morphometrics, approximate Bayesian methods, phylogenetics, social network analysis, etc.) are welcome. Our goal consists of promoting the debate concerning questions like (1) how cultures split, merge, and take form, (2) what kinds of exogenous and/or endogenous factors could explain cycles of stability and changes, and (3) how can we examine cultural traditions in terms of “core” or “packages” systems.

ABSTRACTS

1 SIMULATING THE NEOLITHIC SPREAD ALONG THE NORTHERN MEDITERRANEAN COAST

Fort, Joaquim (Universitat de Girona; ICREA) - Pérez-Losada, Joaquim (Universitat de Girona)

We consider the earliest Neolithic site in each of nine regions located along the northern coast of the western Mediterranean. We perform linear regressions using dates obtained by bootstrap resampling from the corresponding calibrated distributions. In this way, we find a spread rate between 7.5 and 10.6 km/year. Comparing to analytical equations and simulations, this implies that the length of coastal jumps was between 240 km and 427 km. These are the longest dispersal distances so far estimated for a Neolithic expansion. We also find that the importance of cultural diffusion in this Neolithic spread was less than 21%. Therefore, demic diffusion was responsible for at least 79% of the spread rate. On the other hand, comparing our simulations of a genetic cline or gradient to the mitochondrial haplogroups of early Neolithic individuals along the whole northern Mediterranean coast, we estimate that only between 2% and 6% of early farmers interbred with hunter-gatherers.

2 HUNTER-GATHERERS' RESISTANCE IN THE NEOLITHIC OF MEDITERRANEAN EUROPE

Kacar, Sonja (Austrian Academy of Sciences)

Recent aDNA studies reveal an increase in WHG ancestry in some parts of Western Europe, including the Mediterranean regions, more than a millennium after the establishment of the Neolithic in the area (during the Middle/Late Neolithic).

For our comprehension of regional neolithization processes, these results challenge certain paradigms. One prevalent notion is that the local hunter-gatherers were swiftly assimilated after the arrival of the first farmers. Furthermore, the assumption is that only established agricultural communities underwent further developmental trajectories.

Contrary to these assumptions, aDNA evidence suggests a prolonged coexistence of the two societies. It implies that each society may have maintained its distinct way of life, and interactions, initially limited, expanded over time, resulting in subsequent genetic and cultural blending.

Today, evolutionary narratives are nuanced, and prehistorians acknowledge that while certain major evolutionary trends exist, the local trajectories of societies are far from linear. Despite the notion of perpetual progress, societies do not unfold in a straightforward manner. They can simply reject innovations or changes, or even undergo ‘simplification’ by abandoning established assets—either intentionally or unintentionally, due to environmental changes or enemy threats. In fields such as postcolonial studies and anarchist archaeology, these “anomalies” are explored through the concepts of “resistance”, “borderlands” and “margins”.

However, while scenarios of extended coexistence align with our understanding of the Neolithization process as intricate and multifaceted, and find archaeological support in the context of North-Central Europe, such evidence is lacking for Mediterranean.

This presentation aims to tackle how we can archaeologically detect presumed ‘Mesolithic survival’. For instance, in the Adriatic, could a shift towards marine resources during the advanced Neolithic indicate cultural blending rather than a simple diversification of diet? The widespread presence of arrowheads from the Middle Neolithic, could it be indicative of conflicts with surviving hunter-gatherers rather than between distinct farming communities?

3 THE MESOLITHIZATION OF THE ATLANTIC FAÇADE OF THE IBERIAN PENINSULA IN THE LIGHT OF BAYESIAN STATISTICS

Pardo-Gordó, Salvador (Universidad de la Laguna) - Carvalho, António (Universidade do Algarve) - Extrem-Membrado, Vanessa (Universitat de València) - Aura Tortosa, J. Emili (Universitat de València)

The Late Mesolithic (c. 8500-7600 cal. BP) is a subject of intense archaeological study and debate considering the techno-typological changes that took place within the period in many areas of Europe and North Africa, which are characterized by different environmental conditions and cultural trajectories. In this sense, it could be, probably, the first cultural event of the Holocene that unified groups across Europe under a single techno-typology. However, the chronology of its earliest evidence (trapezoidal arrowheads) is still unclear in some regions of southwestern Europe.

This paper aims to present the first chronostratigraphic proposal for the Mesolithic transition process of the Atlantic façade of the Iberian Peninsula. To this end, we first show the protocol used for the selection of radiometric determinations and its subsequent chronological analysis at site scale applying a Bayesian statistic. Then, we will discuss the chronology of the mesolithization process in the area according to the periodization obtained for the Early (so-called Initial Mesolithic in Portugal) and the Late Mesolithic (so-called Geometric Mesolithic in Iberia) techno-typological complexes. Finally, we will show the interactive radiocarbon database where the radiometric information is stored.

4 EVALUATING CULTURAL TRANSMISSION PROCESSES FROM GEOMETRIC PROJECTILES USING EXPERIMENTAL PROTOCOLS: A CASE STUDY FROM THE NEOLITHISATION PROCESS IN EASTERN IBERIA

Donadei, Juan Pablo (Universidad de Valencia) - García puchol, Oretó (Universidad de Valencia)

In this work, an experimental study is undertaken to evaluate the variations generated through different models of cultural transmission. Assuming that cultural transmission processes are mechanisms, in addition to genes, by which acquired variation is inherited from information transmitted between individuals, we can assume that depending on the transmission mechanisms or patterns, we can obtain different combinations of acquired variation. Unfortunately, specialists rarely have access to the complete data from the archaeological record that would allow us to undertake these studies. For this reason, the development of experimental methods allows us to recreate multiple replicates with random assignment of groups to different conditions and obtain a complete data set.

To address the reasons that led to morphological changes in the geometric microliths from the Mesolithic and Neolithic periods of the Mediterranean Iberia, in this experimental proposal, we have worked on two models: the constant-group method (measures variation in social learning and individual learning conditions) and the transmission chain method (measures variation between generations). To do this, each group replicated the manufacture of geometric microliths tools (trapezoids and triangles) which were then analysed by geometric morphometry and multivariate statistical methods.

The results obtained show that materials manufactured under social learning conditions (indirect bias) generate less morphological variation (disparity) compared to those manufactured under individual learning conditions (guided variation). On the other hand, the linear transmission chain shows that, although morphological variation is observed between generations, mainly affecting the elongation index, the general shape of the reference model is preserved in all of them. These results corroborate the hypotheses presented in previous works.

The present work demonstrates that experimental programmes are an interesting tool for studying cultural change and serve as a reference for future comparative studies with the archaeological record.

5 THE ORIGIN AND TEMPO OF NATUFIAN SEDENTISM: A COMPARATIVE META-ANALYSIS OF SUBSISTENCE STRATEGIES

Elbaz, Sigal (Zinman Institute of Archaeology, School of Archaeology and Maritime Cultures, University of Haifa, Haifa, Israel) - Yeshurun, Reuven (Zinman Institute of Archaeology, School of Archaeology and Maritime Cultures, University of Haifa, Haifa, Israel)

The Levantine Epipaleolithic (24–11.7 ky BP) witnessed significant cultural and demographic developments culminating with an increasing degree of sedentism in the Natufian Culture. Research on initial sedentism has raised questions about its origin, and climatic and cultural drivers. Our research asks whether population growth led to the adoption of a sedentary lifestyle. We also aimed to help settle the debate surrounding the pace of cultural change, and whether there was a retreat after it occurred. We employed multiple lines of subsistence evidence, creating the largest database to date that we collected from 63 layers belonging to 42 archeological sites in the southern Levant. The database includes faunal and ground stones assemblages and their chrono-cultural and geographic information. We divided the southern Levant into the Mediterranean and arid zones. In each zone, we compared four chrono-cultural phases, Early Epipaleolithic (~24–18 ka), Middle Epipaleolithic (~18–15 ka), Late Epipaleolithic 1 (Early Natufian, ~15–13.5 ka), and Late Epipaleolithic 2 (Late Natufian, ~13.5–11.7). We tested indices of subsistence diversification, site-occupation intensity, and demographic growth.

In the Mediterranean, unlike the arid zone, the Early Natufian saw abrupt changes in subsistence strategies, resulting from intensification caused by resource depression. This supports the revolutionary nature of the Natufian culture and HBE models suggesting that Postglacial climatic improvements enabled Natufian groups to settle down for various reasons (expanding vegetation, protecting high-value locations, and exceeding residential movement costs of growing communities). Sedentism and population growth reinforced each other and as a result, people were compelled to intensify the exploitation of their local environments. No significant differences were found between the Early and Late Natufian periods, contrasting the ‘retreat to mobility’ model during the Younger Dryas. Moreover, we observed an increase in sites per area in the Natufian period that independently indicates population growth.

6 DISCRETE AND CONTINUOUS TYPOLOGIES: A CASE STUDY FROM EASTERN IBERIA

Rorhus, Katrina (University of Cambridge) - Cortell-Nicolau, Alfredo (University of Cambridge)

One of the most fundamental debates in archaeology is on the dichotomy between what the biologist Ernst Mayr (1959) calls “typological thinking” and “population thinking”. Drawing on the principles of biological evolution and the philosophical schools of empiricism versus positivism, typology is a multidisciplinary framework that is used to create order in fields that deal with large numbers of variable individuals. However, although the use of types in archaeology is widespread and almost subconscious, other disciplines (e.g. biology and philosophy) have moved away from this kind of thinking towards a more continuous, gradual, population thinking approach. To explore whether archaeology should emulate these changes, we looked at the morphologies of over 2000 geometric microliths from Eastern Iberia. These lithics are largely typed on the basis of morphology, and are therefore a good candidate to explore the legitimacy of archaeological ‘types’ and whether geometric microliths can be taxonomically described as wholly “discrete” or “continuous”. Through the combination of clustering methods and statistical regression, based on Geometric Morphometrics analysis, we characterise the differences between the morphologies of lithics of different types, and we assess the relationship between classic types and the continuous distribution of the arrowheads across the entire morphospace. Finally, potential ontological and taxonomic alternatives are offered.

7 DIPS AND UP-TICKS: EXPLORING POPULATION DEMOGRAPHICS OF THE NEOLITHIC ON THE DALMATIAN COAST OF CROATIA

LoBiondo, Matthew (University of California Santa Barbara) - McClure, Sarah (University of California Santa Barbara) - Podrug, Emil (Muzej grada Šibenika, Šibenik, Croatia)

The Dalmatian coast of Croatia has a long history of archaeological investigation of Neolithic lifeways that have documented shifts in material cultural and agro-pastoral practices. Expanding on this work, recent research has highlighted the importance of the Dalmatian coast as a key area for understanding the mechanisms and effects of the spread of agriculture. Scholars have detailed diachronic and coetaneous changes in socio-ecological and material culture economies alongside evolutionary trajectories. To contextualize the tempo and impact of changes in early farming strategies, we provide a reconstruction of Neolithic (~6000–4500 calBCE) population dynamics for Dalmatia using summed probability distributions and cumulative kernel density estimates of calibrated radiocarbon dates. Our demographic reconstructions indicate shifts in Neolithic subsistence strategies likely effected population levels. Previous scholarship has demonstrated that the development and production of fermented dairy products circa 5200 cal BCE and suggested it may have reduced infant mortality and lead to demographic shifts that enabled farming communities to occupy northern latitudes. Using demographic reconstructions we investigate if the production of these fermented

products not only facilitated movement to northern regions, but also resulted in a local population boom of middle Neolithic farming populations in Dalmatia.

8 POPULATION STRUCTURE AND TECHNOLOGICAL VARIABILITY IN THE NEOLITHIC CERAMIC ASSEMBLAGES OF DEHESILLA CAVE (SOUTHERN SPAIN)

Díaz-Rodríguez, Manuel (University of Seville) - Garcia-Rivero, Daniel (University of Seville)

Recent excavations in the Dehesilla Cave (Southern Spain) have provided a Neolithic sequence spanning from the mid-6th millennium cal BC to the mid-4th millennium cal BC. In this presentation, we address the technological diversity of the ceramic assemblages within and between the different chronological periods of the Neolithic occupation.

For this purpose, we have used the Analysis of Molecular Variance (AMOVA) and the PhiST statistic, which have been applied to the study of cultural variability for some years in diverse papers. This analysis provides a quantitative measure of whether and to what extent the observed ceramic assemblage is characterised by different populations, archaeological periods in this case.

Through this analysis, we will examine the degree to which period affiliation is comparable to an actual population structure (when individual subpopulations/groups show low variability within and high variability between pairs of groups). Moreover, the results of these analyses allow us to test the theoretical validity of the archaeological units of analysis as discrete and arbitrary groupings of a continuous set of variability or as coherent units amenable to future analysis.

9 EVOLUTIONARY HISTORIES OF THE NEOLITHISATION PROCESS IN THE MEDITERRANEAN: CROSSING POPULATION AND CULTURAL DATA

García-Puchol, Oreto (Universitat de Valencia) - Cortell-Nicolau, Alfredo (University of Cambridge) - Bernabeu-Aubán, Joan (University of Valencia) - Díez-Castillo, Agustín (University of Valencia) - McClure, Sarah (University of California Santa Barbara) - Gallelo, Gianni (University of Valencia) - Barrera-Cruz, María (University of Valencia)

Understanding patterns and processes of cultural change constitutes a crucial aspect of tracing social structure dynamics triggered by the neolithisation in a “longue durée” view. In this paper, we focus on the Central and Western Mediterranean as a part of the framework of the Evolmed project “PID2021-127731NB-C21: Evolutionary cultural patterns in the framework of the neolithisation process in the Western Mediterranean”. We aim to investigate the cultural trajectories in the context of the Neolithic spread assuming that the process encompasses a scenario involving demic expansion and opportunities for interaction. Recent works have contributed to testing the explanation of the Neolithic dispersal through the Mediterranean corridor taking into account demic and interaction processes using mathematical modelling, exploring relative demographic dynamics from SPDs, and evaluating the evolutionary hypothesis of cultural change. In this paper, we explore patterns of cultural variability in space and time trying to solve questions concerning the evolutionary forces behind them from a diachronic view (from 8500 to 6500 cal BP). The SPDs created will serve to compare relative population histories with relevant hypotheses of cultural change. The fluctuations (cycles) observed will be confronted with the dynamics of cultural variability. This work will be based on the relational databases hosted at the University of Valencia in the settings of several research projects aimed at compiling radiocarbon dates and cultural material data, currently expanded to a wide area, including the central-Northern Mediterranean and the Western Mediterranean.

10 NEURAL NETWORKS ASSISTING SOCIAL NETWORKS ANALYSIS TO MAP NEOLITHIC-CHALCOLITHIC DOLERITES CIRCULATION IN VALENCIA COMMUNITY (SPAIN)

Gallelo, Gianni (University of Valencia) - Jimenez-Puerto, Joaquín (University of Valencia) - Trull-Dominguez, Oscar (Polytechnic University of Valencia) - Bernabeu, Joan (University of Valencia)

Neolithic-Chalcolithic groups in the Mediterranean region of the Iberian Peninsula developed high technical capabilities in the manufacturing of dolerite artefacts. In an attempt to observe social relationships between these societies in Valencia Community (Spain) area several dolerite materials found in different archaeological sites and their potential raw material sources were studied. The materials were analysed employing a portable X-ray fluorescence spectroscopy, directly measuring the rock surface. The obtained data were processed by elemental relation and ratios calculations and through neural network protocol (SOM), to observe archaeological and geological samples distribution.

The identification of outcrops sources of dolerite artefacts used unsupervised machine learning algorithms, effectively mapping out similarities. The methodology has been enhanced by applying algorithms suited for analysing small-sized samples, facilitating a more nuanced understanding of the geochemical variability among artefacts. By doing this we

enable the observation of possible relations between the Neolithic-Chalcolithic communities in the Valencia region and the circulation of the analysed artefacts through social network analysis (SNA).

The integration of Machine Learning (ML) findings into SNA provides a novel methodological approach, allowing for the exploration of the social dimensions of artefact distribution and exchange networks. This approach not only sheds light on the technological and economic aspects of these ancient societies but also offers a window into their social structures and interactions. By employing a combination of ML and SNA, this study shows the potential of interdisciplinary methods in archaeology to uncover complex social and economic relationships in prehistoric communities.

Finally, the processed dolerite chemical information obtained was employed running SNA to observe the possible relations between the Neolithic-Chalcolithic communities in the Southern Valencia region and the circulation of the analysed artefacts. The results showed evidence of a common raw material procurement pattern at regional level, and nature and size limitations of the sample were evaluated.

1111 NON-INVASIVE ARCHAEOLOGY: INTEGRATING SATELLITE, UAV, AND GEOPHYSICS WITH TRADITIONAL FIELD METHODOLOGIES

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Peters, Manuel J.H. (Montefortino Prospection & Digitalisation, Max Planck Institute of Geoeanthropology) - Wroniecki, Piotr (Montefortino Prospection & Digitalisation) - Trapero Fernández, Pedro (Cádiz University)

Session format: Regular session

The archaeological workflow is being revolutionised by non-invasive methods such as geophysics and remote sensing. Their application is increasingly prevalent due to their lower cost and increased ease of use. Examples include satellites and piloted aerial vehicles (UAVs) with RGB, laser, and spectral sensors; geophysical techniques such as magnetometry, GPR, and resistivity; and Artificial Intelligence (AI) for data collection and interpretation.

Compared to traditional approaches, these methods are a fast way of acquiring large datasets. Their systematic integration needs further exploration however, in order to unlock the true potential of these methods when seamlessly embedded into the archaeological process. This integration ranges from large-scale approaches to study sites and landscapes, to more focused applications in excavation data analysis.

Challenges can arise due to the interdisciplinary nature of these approaches, where external specialists may not fully grasp the archaeological needs, and archaeologists may not entirely understand the possibilities and limitations of the techniques. Furthermore, data processing remains complex; a technical understanding of the method itself is often required, and the standard process does not always align with the requirements of an archaeological context. This makes data visualisation challenging, especially for techniques such as GPR and LiDAR.

This session explores the dynamic relationship between non-invasive technologies and traditional methods in research-driven and development-led archaeology. We invite contributions dealing with the integration, comparison, and validation of non-invasive and invasive methods, including the use of remote sensing, geophysical prospection, pedestrian survey, coring, and excavation. Digital aspects of the workflow, including GIS, spatial analysis, and Artificial Intelligence, are also welcomed. Reflections concerning the theoretical and technical application of non-invasive methods are invited, as well as insights and considerations regarding methodology, potentially aligning with broader efforts to standardise methodologies and datasets across projects and regions. We encourage the evaluation of both successful and unsuccessful outcomes.

ABSTRACTS

1 REAPING THE BENEFITS OF LEAF-ON AIRBORNE LASER SCANNING DATA FOR CROPMARK ARCHAEOLOGY

Banaszek, Lukasz (Historic Environment Scotland)

Applications of airborne laser scanning (ALS) in archaeology have tended to focus on examining surface topography. Less well explored is the potential for such data to investigate levelled archaeological features that are expressed through differential arable crop growth (cropmarks). This is partly because airborne lidar surveys tend to take place outside the growing season, limiting the potential to explore this aspect of lidar data worldwide.

However, Scotland has blocks of data collected at the peak period for cropmark formation which cover 4814 archaeological sites recorded as cropmarks. This provides a unique dataset to evaluate airborne laser scanning data against traditional aerial reconnaissance outcomes across the Scottish Lowlands.

Also drawing on Sentinel-2 satellite imagery and targeted field visits, this paper evaluates the utility of large-area leaf-on airborne laser scanning data in recording cropmark archaeology. The outcomes of this study are relevant to archaeological survey in arable landscapes across Europe and beyond.

2 LANDSCAPE UNDER THE POINT CLOUD: UNVEILING THE PAST WITH ENHANCED VISUALISATION AND HIGH-RESOLUTION LIDAR DATA FROM SLOVAKIA

Lieskovský, Tibor (Department of Theoretical Geodesy and Geoinformatics, Faculty of Civil Engineering, Slovak University of Technology in Bratislava) - Ďuračiová, Renata (Department of Theoretical Geodesy and Geoinformatics, Faculty of Civil Engineering, Slovak University of Technology in Bratislava)

Since 2018, Slovakia has joined the list of countries with available airborne laser scanning data for the whole territory. Data provided by the Geodesy, Cartography, and Cadastre Authority of the Slovak Republic are free to use and accessible as a classified point cloud with a density of the last return of 20 – 40 points per sq. meter.

We used the point cloud to interpolate digital elevation models with resolution of 25 cm/pixel for the entire territory and of 10 cm/pixel for selected areas with remnants of architecture in a ruinous state. We are developing an integrated high-resolution visualisation of these data to integrate multiple data visualisation approaches into a unified form, increasing the efficiency of detecting different types of archaeological features in various types of landscape.

We present our experiences with the use of high-resolution LiDAR data and specialised visualization techniques for identification and interpretation of archaeological features structure remains, integrating these data with other sources, such as archaeological databases, geophysical surveys, and old maps and plans. We show examples of uses in applications such as the refinement of historical maps, research in the field of landscape archaeology and ecology, and public outreach.

This work was supported by the Slovak Research and Development Agency under Contract no. APVV-22-0151.

3 THE RIGHT PLACE AT THE RIGHT TIME - AIRBORNE RGB DERIVED SLOPE MAPS AS GUIDE FOR UPLAND ARCHAEOLOGY FIELD SURVEY

Zanotti, Erik (Università of Bologna) - Putzolu, Cristiano (Università of Bologna) - Fiorini, Silvia (Università of Bologna) - Debandi, Florencia (Università of Bologna) - Cavazzuti, Claudio (Università of Bologna)

Here we present a case study of blended approach between field survey and UAV support when confronting particularly problematic contexts such as the uplands, and in this case the northern Apennines (Italy). The widespread presence of forestall coverage, combined with the hilly nature of this landscape often prevent systematic survey to achieve convincing results, especially when focusing on prehistoric settlements whose visibility is usually low. With this background, we looked for alternative methods to survey mountain sites, not just with the aim of identifying potential signs of structural remains, but also searching for a cost-effective solution to plan long term exploration for the researched area. Being well acquainted with the impressive, yet still expensive, results of airborne LiDAR technology, we employed “regular” RGB drones for less analytical purposes. In a landscape profoundly conditioned by seasonal climatic shifts, both with regard to the thickness of vegetal canopy and presence of snow on the higher peaks during increasingly shorter winter seasons, we suggest that choosing the right moment of the year could overturn our point of view on the discrepancy of results attainable with these two diverging methodologies. Stressing the importance of well-tuned post-processing procedures, deriving from the elaborations of DTM’s rasters obtained from aerial orthophotography, we tried to expand the range of possible strategies when dealing with apparently impenetrable grounds. Presenting both “successful” and unsuccessful examples of post-processed data acquired during mid-seasonal drone surveying campaigns, we advocate for a potentially proficient use of analogical technologies when investigating upland contexts, eventually putting the accent on the need of ground truthing steps to come full circle.

4 ALL FEATURES GREAT AND SMALL: COMPARING LIDAR SYSTEMS AT ANCIENT MAYA SITES IN BELIZE

Thompson, Amy (The University of Texas at Austin) - Willis, Mark (Flinders University) - Houk, Brett (Texas Tech University) - Fernandez-Diaz, Juan Carlos (University of Houston)

The increasingly common use of light detection and ranging (lidar) in the field of archaeology has fundamentally transformed our understanding of landscapes, human-environment interactions, and social organization. Combining lidar with traditional pedestrian survey we can explore the dynamic relationship between field-verified and remotely-sensed data. In this paper, we examine two classes of lidar data collected at ancient Maya sites in the Belize Estates Archaeological Survey Team (BEAST) permit area in northwestern Belize. In this heavily forested region, traditional settlement mapping is slow and expensive: archaeologists have only mapped 6.5 km² using traditional pedestrian survey since the late 1990s. Therefore, the ability to map large areas with lidar is literally game changing. In conjunction with the National Center for Airborne Laser Mapping (NCALM), in 2022 we collected approximately 650

km² of crewed aircraft lidar data using the Titan sensor, providing a new understanding of settlement patterns, social organization, and landesque capital across the landscape. In 2023, we collected 5 km² of UAV/drone-lidar data using a Zenmuse L1 lidar sensor attached to a DJI Matrice 300 multirotor drone. The drone survey overlaps with the NCALM data, focusing on the kingdom of Chan Chich and the minor center of Gallon Jug; these sites are located on landscapes of varied modern land use practices including a manicured resort, cattle pasture, and non-managed jungle foliage. Here, we compare the effectiveness of crewed-aircraft and drone lidar in landscapes of varying modern land management strategies and vegetation density with respect to coverage, cost, and data quality. Integrating the pedestrian survey data, we conduct accuracy assessments of these two technologies. Rather than finding one lidar sensor better than the other, we highlight the synergies of using a multi-method approach to understanding ancient landscapes while incorporating the impact of modern anthropogenic activities to our understanding of past human behaviors.

5 THE EDUCATION MOAT SURVEY IN BENIN CITY: USING GEOMATIC TECHNIQUES FOR AN ARCHAEOLOGICAL SURVEY

Hubert, Jan (Deutsches Archäologisches Institut)

The Education Moat Survey in Benin City aimed to comprehensively study the so-called inner moat or Iya systems together with MOWAA and the German Archaeological Institute. These earthworks are encircling Benin City, but smaller networks can be found in the periphery as well. For the survey advanced geomatic science tools are employed. The survey integrates 3D photogrammetric overflights, assessed the condition of the eastern inner moat, mapped community boundaries, and trained MOWAA geomatic specialists. Cutting-edge technologies like the Mavic 3E drone, DJI Matrice 300 RTK with Lidar, Emlid Reach RTK GNSS receiver, photogrammetric as well as GIS software were utilized.

The methodology made use of satellite imagery for basemaps, UAV surveys with RGB cameras, LiDAR for detailed 3D models, high detailed orthographic imagery as well as digital elevation models. To verify the results from remote sensing, on-site ground surveys with mobile GIS apps connected to RTK GNSS receivers, and GIS for data post-processing was employed. Results provided insights into the moat's condition, course, and cultural significance. Combining technology with the transmission of oral history by the communities, the study mapped community boundaries, located shrines, and documented landmarks. Ground surveys so far validated aerial data, revealing an immense loss in the moat's original extent in the eastern part of the inner city.

Beyond the specific case the importance of geomatic science in African and Nigerian archaeology is rising across the continent. Nevertheless, there is untapped potential as these tools become more affordable, with many programs, like QGIS, even available for free. To fully harness these advancements, researchers need to stay informed and receive training in these emerging methods, enabling them to recognize the benefits and apply them effectively in their archaeological research. Edocation ensures sustained research in Benin City beyond 2024 by empowering archaeologists with vital training and tools.

6 RECONSTRUCTING THE DIFFERENT BUILDING PHASES AT THE CASA DEL CITARISTA IN POMPEII (ITALY) USING GROUND PENETRATING RADAR (GPR)

Corradini, Erica (Institute of Geosciences, Christian-Albrechts-University Kiel, Germany) - Busen, Tobias (Deutsches Archäologisches Institut (DAI), Berlin, Germany) - Haug, Annette (Institute of Classics | Classical Archaeology, Christian-Albrechts-University Kiel, Germany) - Erkul, Ercan (Institute of Geosciences, Christian-Albrechts-University Kiel, Germany) - Fischer, Simon (Institute of Geosciences, Christian-Albrechts-University Kiel, Germany) - Stuempel, Harald (Institute of Geosciences, Christian-Albrechts-University Kiel, Germany) - Rabbel, Wolfgang (Institute of Geosciences, Christian-Albrechts-University Kiel, Germany)

The Casa del Citarista on Insula I 4 in Pompeii is amongst of the largest in the city with an extension of 2700 square meters, and reached this extent thanks to the progressive incorporation of various properties. This complex building process led to the development of an irregular plan, with two atria and three peristyles. The extension visible today might have been reached in the first century AD, and it belonged to members of the very powerful Popidii family. We present a GPR survey conducted in addition to architectural investigations undertaken on site. The GPR survey was done with a GSSI dual frequency (300 and 800 MHz) antenna with the aim to detect building structures lying below the existing ancient floor levels. The southern sector of the Casa del Citarista shows different GPR reflectors which can be assigned to the different building phases identified during the architectural survey. In particular, reflectors between 0.5m and 1.20m confirm the assumption that at least two anterior houses (I 4,A and I 4,B; 3rd/2nd century BC) were incorporated during time. During the 2nd/1st century BC the original atrium house expanded to the northeast, delivering the construction of a porticus, whose floor is visible in the GPR record as well. A third construction phase occurred during the Late Republican and brought to the establishment of two peristyles. The discovered elements like a drainage channel for the new reservoir in the central peristyle and a water drainage channel from the

peristyle roof on the east highlight the hydraulic engineering work between the two peristyles. The most surprising result was the detection of a cistern in the northern sector. Due to a 3D modeling we were able to reconstruct its shape including the bottom and a transversal passage at the southern edge.

7 FEATURE DETECTION IN THE ARGENTINEAN ANDES: MULTISCALE ASSESSMENT OF SATELLITE, UAV, AND SURVEY DATA

Peters, Manuel J.H. (Max Planck Institute of Geoanthropology) - Jambajantsan, Amina (Max Planck Institute of Geoanthropology) - Zuccarelli, Veronica (Max Planck Institute of Geoanthropology)

The Cusi Cusi micro-region in the Argentinean Andes presents a unique challenge for archaeological research. This rugged area is situated within the Puna of Jujuy at an elevation ranging from approximately 3800 to 4200 meters above sea level, and is characterised by plains interrupted by sharp changes in elevation. The archaeological, historical, and modern features existing in the region attest to a long-term human presence and include cattle enclosures, habitational structures, retaining walls, perimeter walls, burial mounds, and agricultural terraces.

The Puna of Jujuy is situated in the "Lithium Triangle", an area that includes territories in Argentina, Bolivia, and Chile, holding 60% of the lithium in the world. As a result of the political reforms of 2023 and 2024, the dynamics concerning indigenous rights and underground resource ownership are increasingly complex. In particular, new extractive politics are bringing increasing pressures on indigenous landownership and environmental stability. This situation illustrated the growing importance of documenting the region, both its archaeological heritage as well as the contemporary circumstances of indigenous communities.

This research integrates satellite and UAV imagery with pedestrian survey datasets, machine learning, and physical ground-truthing. Specifically, we undertake a multiscale assessment of automated feature detection on satellite data and high-resolution UAV-based photogrammetry to determine their effectiveness in detecting and analysing various features. The validation process included on-site ground-truthing visits, providing insights into the heritage and challenges of the Cusi Cusi micro-region.

8 NEW WAYS TO SEE THE SURFACE. A CASE STUDY FROM THE MEGALITHIC PHENOMENON OF THE SOUTHEAST OF THE IBERIAN PENINSULA

Cabrero, Carolina (University of Granada) - Garrido, Antonio (University of Jaén) - Esquivel, Francisco Javier (University of Granada) - Cámara, Juan Antonio (University of Granada)

The megalithic cluster of the Gor River valley (Andalusia, Spain) is one of the biggest dolmenic groups in Europe, with 238 tombs registered during the first general campaign by the end of the 19th century. Despite its high potential for the research on megalithism and for the understanding of the prehistoric societies of the area, the scarcity of modern archaeological works and the lack of protection measures have led to the loss and destruction of a big part of the group, as only 151 megaliths were possible to find during the last surface survey carried out in 2019. With the aim of recording the location of these lost megaliths, Digital Terrain Models and LiDAR data, both publicly available thanks to the Spanish National Geographic Institute, have been used to analyse the terrain, permitting the location of 230 structures similar in shape and size to those actually documented on the surface, but that were not noticed until this remote survey. In order to test this high quantity of possible megalithic structures, a new surface survey by traditional means has been carried out in three selected areas of the cluster chosen for sampling. This new combined survey has led to the verification of 10 out of 25 possible locations, given also very interesting new data for areas that were recently studied by traditional means, making it clear that the application of new techniques leads to new results even in the most revised areas. The survey has permitted also to test the possibilities and limitations for this type of digital survey of the terrain applied to the megalithic phenomenon of the Southeast of Iberia, characterized by the presence of small burial chambers, which allows to test the limit of the resolution of this kind of mapping and its application for small-sized archaeological structures.

9 THE VILLA SETTE BASSI RELOADED: INTEGRATING UAV AND SATELLITE DATA FOR AN HOLISTIC MONITORING OF CULTURAL HERITAGE

Clementi, Jessica (Department of Earth Sciences, Sapienza University of Rome) - Sanvito, Veronica (Department of Earth Sciences, Sapienza University of Rome) - Marini, Roberta (Nhazca s.r.l.) - Molinari, Antonio (Department of Earth Sciences, Sapienza University of Rome) - Massi, Andrea (Department of Physics, Sapienza University of Rome; Nhazca s.r.l.) - Roascio, Stefano (Ministero della Cultura, Parco Archeologico dell'Appia Antica) - Reginaldi, Michele (Ministero della Cultura, Parco Archeologico dell'Appia Antica) - Mazzanti, Paolo (Department of Earth Sciences, Sapienza University of Rome; Nhazca s.r.l.)

Detecting and monitoring deformations that affect cultural heritage sites and their surroundings is a crucial aspect in developing preservation strategies, especially in the case of extensive archaeological areas. A collaboration agreement

for joint research promoted in 2022 by the MiC – General Directorate of Cultural Heritage Security and the CERL Research Center, University of Rome Sapienza aims at ensuring the security of the cultural heritage and deepening its knowledge and conservation. The Villa Sette Bassi archaeological site, one of the largest residences in the Roman suburbio, is chosen as the case study. Following the canonical scheme of the monumental villas of the Roman countryside, the complex consists of several pavilions developed around a large garden. The residence also had its own aqueduct, today preserved for a long stretch. The application of integrated non-invasive methodologies (i.e. Change Detection analysis of various types of images including optical, multispectral, thermal, and radar images acquired from satellite and UAV platforms; the differential SAR interferometry (DInSAR) and the Advanced DInSAR (A-DInSAR) techniques) offers valuable information about the spatial and temporal evolution of the identified changes or displacements. The products of these processing chains will be integrated and managed by a GIS platform, that can ultimately generate products (maps) as concrete support for the authorities responsible for the protection of the archaeological heritage, thus for the monitoring of both the exposed and still unexcavated archaeological heritage and the planning of effective and preventive conservation activities.

10 THE 2023 FIELD EFFORTS AT COLHA: INTEGRATION OF MAGNETOMETRY AND EXCAVATION; AND A RETURN TO TZAK NAAB FOR GEOPHYSICAL SURVEY

Neuhoff-Malorzo, Patricia (Independent Researcher; SWCA Environmental Consultants) - Adam, Manda (University of Texas at Austin) - Valdez, Jr, Fred (University of Texas at Austin)

The 2023 field season in Northern Belize focused on a return to the site of Colha combining new methodologies and excavation efforts in the search for Maya Preclassic and Postclassic evidence. Additionally, the 2023 season included training of students in geophysical survey at the site of Tzak Naab, with the intent to return in 2024 to ground truth the results of the geophysical survey. The overall field program allowed for new geophysical surveys at the sites of Colha, and Tzak Naab. These surveys facilitated the continuation of previous research avenues as well as new research into the Postclassic.

During the 2023 field season at Colha research into the identification of the Maya Postclassic, was directed by Manda Adam. Geophysical surveys, specifically magnetometry, were conducted under the direction of Dr. Patricia Neuhoff-Malorzo. The magnetometry surveys identified several structural delineations which were complemented by excavation efforts. Leading to the successful identification of Postclassic evidence.

The search for the Preclassic, under the direction of Dr. Fred Valdez, was conducted in the main plaza area and included both geophysical survey and targeted excavation efforts. Magnetometry survey was limited due to time and space but served to direct excavation efforts and resulted in the discovery of an undated wall. Further examination of the survey and excavation data provides direction for targeted efforts in future seasons.

The field efforts at the site of Tzak Naab focused on student training in magnetometry survey and the search for evidence of activity areas. In addition, the field efforts served to repeat previous seasons evidence with extensive discussion based on how geophysical survey can direct excavation efforts for future seasons. This data directed the 2024 excavation efforts.

11 NEW TECHNOLOGIES FOR THE PRESERVATION OF PRE-COLUMBIAN ARCHAEOLOGICAL HERITAGE IN SOUTH AMERICA: THE MAPHSA PROJECT

Moderato, Marco (CASES, Universitat Pompeu Fabra, Spain) - de Souza, Jonas (CASES, Universitat Pompeu Fabra, Spain) - Madella, Marco (CASES, Universitat Pompeu Fabra, Spain) - Tapscott Baltar, Alan (CASES, Universitat Pompeu Fabra, Spain) - Heidgen, Shaddai (CASES, Universitat Pompeu Fabra, Spain) - Fajardo Bernal, Sebastian (Leiden Institute of Advanced Computer Science (LIACS), Leiden University, the Netherlands) - Vargas Ruiz, Juan Carlos (Universidad del Magdalena, Colombia) - Neves, Eduardo Góes (Museum of Archaeology and Ethnology, University of São Paulo, Brazil) - Strauss, André (Museum of Archaeology and Ethnology, University of São Paulo, Brazil)

This contribution explores comprehensive methodologies employed by the Mapping the Archaeological Pre-Columbian Heritage in South America (MAPHSA) project, integrating transregional datasets from Brazil and Colombia. The project encompasses a broader range of cultural heritage and enabling cross-cultural comparisons aiming to establish an integrated database incorporating both legacy and newly acquired information related to the pre-Columbian archaeological heritage of South America. Embracing the FAIR data standard sharing philosophy, MAPHSA endeavors to provide an open-access digital resource.

This innovative undertaking marks the inception of the first-approach of geospatial and data repository singularly devoted to the contextualized mapping of archaeological heritage in Brazil and Colombia. Beyond its immediate geographical impact, the database serves the research community within the surveyed countries, as well as the broader international archaeological community and national heritage agencies. Through these efforts, MAPHSA

makes a substantial contribution to the advancement of heritage preservation and the facilitation of interdisciplinary cross-border studies.

MAPHSA adopts a multidisciplinary approach that combines archival work, remote sensing, machine learning, and on-ground surveys to meticulously identify and assess the preservation status of archaeological sites. The workflow seamlessly integrates diverse datasets into a Postgres/PostGIS geodatabase, utilizing the Arches information management platform with a CIDOC CRM ontology data model. Drawing on the experience garnered from similar-scale Arcadia-funded projects, MAPHSA establishes itself as a trailblazer in the field.

This initiative extends beyond technical aspects, fostering international awareness about the vulnerability of South American heritage to threats like deforestation, agricultural expansion, and fire, aiming to catalyze a paradigm shift in public perception and stimulate concerted preservation efforts, particularly in culturally significant areas like the Amazon and Cerrado savanna.

In summary, MAPHSA pioneers seamless integration of a comprehensive database and multidisciplinary methodology, setting a precedent for meticulous archaeological mapping and advocating global awareness and protection of South American cultural heritage.

12 AN INTEGRATED GEOPHYSICAL INVESTIGATION OF THE PREHISTORIC LANDSCAPE IN THE FORESTS OF SCHALTENRAIN, SWITZERLAND

Medaric, Igor (University of Zurich, Department of Archaeology; University of Ljubljana, Department of Archaeology) - Geitlinger, Timo (University of Zurich, Department of Archaeology) - Blum, Jonas (University of Zurich, Department of Archaeology) - Della Casa, Philippe (University of Zurich, Department of Archaeology)

This presentation will focus on the preliminary geophysical survey results and discuss their potential in detecting prehistoric remains in densely forested environments. During the winter of 2023/24, an extensive multi-method geophysical survey was conducted in the forests of the Schaltenrain hills in the Bernese Seeland region of NW Switzerland. The survey targeted small key areas within the extensive forest landscape, focusing on significant archaeological features identified by previous surveys or through analysis of airborne laser scanning (LIDAR) data. These features included burial mounds, terraces, potential communication routes, and potential remains of prehistoric settlements. By investigating these key locations, the geophysical survey aimed to provide more information to help reconstruct the prehistoric landscape. The results were then validated by coring and test-pitting several of the identified anomalies to improve the interpretation of the geophysical data. This validation process was crucial not only to improve the understanding of the various archaeological features, but also to assess the applicability of different geophysical methods on these structures. The ultimate promise of this research is to provide a comprehensive overview of specific natural environments, working procedures, and processing steps. It can serve as a fundamental framework increasing the efficiency of the application of geophysical methods to the chosen geopedological forest context and to similar settings in the future.

13 BARCZEWKO/ALT WARTENBURG - UNCOVERING AN ABANDONED MEDIEVAL TOWN THROUGH AERIAL PHOTOGRAPHY, GEOPHYSICS, AND EXCAVATIONS

Koperkiewicz, Arkadiusz (Institute of Archeology, University of Gdansk) - Wroniecki, Piotr (Montefortino Prospection & Digitalisation)

Barczewko is a town in Poland, situated in the historical region of Warmia. Originally home to Prussian tribes, it was conquered in the Medieval by the Teutonic Order, establishing a powerful state along the Baltic Sea. This state included autonomous episcopal domains, with Warmia at its heart. Nicolaus Copernicus and Aeneas S. Piccolomini (who would later become Pope Pius II) were active in the area. The Order was engaged in extensive military campaigns to conquer Lithuania. Medieval chronicles note that one of the bishops founded the town of Wartenberg in 1325. A sudden Lithuanian attack in 1354 caught the inhabitants during their daily routines. The sudden raid and fire rapidly consumed the settlement, representing a classic “Pompeian scenario”. The relics reveal the spatial layout of the early urban colony and the cemetery of its first settlers. The rediscovery of its significance was facilitated by non-invasive surveys revealing a veritable time capsule. The site was transformed, and the new non-urban settlement was similarly named, with the prefix “Alt”. The hill behind the village was known as the Old Town, enabling the placename to endure to the present day.

In our presentation, we will demonstrate how each urban element was archaeologically identified and verified against a map of geophysical anomalies. By using specific examples, we aim to provide a comparative analysis of stratigraphic units that were sources of geophysical anomalies. The majority of verifications were positive. Besides its historical significance, the site has become a benchmark for interpreting and understanding geophysical anomalies in the study of abandoned Medieval urban sites.

Research funded by the National Science Center, project 2021/41/B/HS3/01694 titled “Barczewko – A History Written by Fire. The Medieval Lost City and Urbanization of the Galindian Forest” 2022-2024.

14 THE USE OF NON-DESTRUCTIVE METHODS TO RECONSTRUCT THE SETTLEMENT STRUCTURE OF HIGH AND LATE MEDIEVAL VILLAGE LHOTKA

Petráš, Josef (Independent Researcher)

Geophysical methods have become an integral part of non-destructive archaeology in the 21st century, with their main advantage being the accuracy and speed of prospection. In particular, magnetometry and GPR methods have proven to be very useful in locating archaeological objects. These methods were used in the reconstruction of the internal and external areas of the abandoned High and Late Medieval village of Lhotka. This village is located in the area of the former Brtnice manor, situated in the Bohemian-Moravian Highlands. Its abandonment is dated by written sources before 1399, when it first appears as deserted. Using a hand-held magnetometer and GPR, several home-steads, their orientation and position in the internal area were identified. The geophysical prospection also identified anomalies in the area of the presumed village square and the location of a modern coal mill. The combination of mutually verifying methods was ultimately further supplemented by verification using other non-destructive methods such as the use of metal detector, microprobe, radiocarbon dating or phosphate analysis of soils. A 3D model of the site was created using UAVs, which was used to generate the DEM, and the remainder of the field of the vanished village was discovered using LiDAR. Thanks to the interplay of all methods, it was possible to reconstruct the approximate form of the village, its economic background, the original burial horizon and to place it in the historical context of the settlement.

15 GEOPHYSICS AND ARCHAEOLOGY ON THE TRAIL OF THE OTTONIAN KINGS AND EMPERORS - THE MEDIEVAL CENTRE OF POWER AT MEMLEBEN

Biermann, Felix (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle (Saale); University of Szczecin) - Grönwald, Holger (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle (Saale)) - Heikkinen, Mikko (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle (Saale)) - Meller, Harald (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle (Saale)) - Wehner, Donat (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle (Saale))

Memleben on the river Unstrut (Saxony-Anhalt, Germany) is of great historical importance, as the Ottonian King Henry I († 936) and his son, Emperor Otto the Great († 973), died here. For a long time, researchers have been trying to understand the design, structure, topography and functioning of the early and high medieval centre of power, which consisted of the palace ("Pfalz"), a monastery, at least one hillfort, several open settlements and a market site. In particular, the location of the Pfalz has been unclear for a long time. A current major research project (State Office for Heritage Management and Archaeology Saxony-Anhalt, Halle [Saale]) is providing important information in this regard, using large-scale geophysical prospections (magnetic survey currently covering more than 58 hectares, ground penetrating radar, electromagnetic induction survey, electrical resistivity tomography), field surveys and extensive excavations. Large-scale magnetic surveys were carried out along the Unstrut river valley at potential sites based on both historical sources and aerial photos, followed by both excavations and further surveys in detail informed by the magnetic results. These in turn informed each other, resulting in a mutually supporting network of research. The project has been agile and able to call up detail surveys to clarify specific questions on very short notice. This has not only provided important new insights into the medieval Pfalz and settlement complex, but has also yielded interesting methodological insights when comparing the results of various geophysical and archaeological investigations. The lecture will provide an overview of this project with a methodological focus.

16 UNDERSTANDING AN ANOMALY. INTEGRATION AND INTERPRETATION OF NON-INVASIVE DATA IN THE OSTROWITE ARCHAEOLOGICAL PROJECT (NORTHERN POLAND)

Sikora, Jerzy (Institute of Archaeology University of Lodz) - Wroniecki, Piotr (Montefortino Prospection @ Digitalisation)

The long-term archaeological project at Ostrowite in Pomerania, Poland, offers a unique opportunity to assess, confirm, and integrate diverse archaeological and environmental data. Uncovering evidence of human activity spanning from the Late Palaeolithic to significant Early Neolithic, Early Iron Age, Roman Period, and Medieval (11th-14th centuries) phases, the site has served as a testing ground for a variety of non-invasive and invasive archaeological techniques since 2006. The project has conducted numerous aerial surveys (manned and unmanned), comprehensive geophysical surveys using magnetic gradiometry, earth resistance, and GPR methods, ALS data analysis, phosphate and surface surveys, including metal detection, alongside extensive environmental analyses integrated with GIS.

This approach has facilitated the creation of a guide for interpreting various geophysical anomalies and cropmarks, aiding in the reconstruction of the site's settlement landscape across different periods. The prevalent use of non-invasive techniques and GIS integration has also shaped the excavation strategy, leading to the deployment of small test trenches to investigate specific locations, anomalies, or cropmarks, eliminating the need for extensive trenching.

Simultaneously, detailed excavations in areas susceptible to agrotechnical damage have not only verified the findings from non-invasive surveys but also enriched our catalogue of anomalies and cropmarks, enhancing our understanding of the site.

17 NON-INVASIVE RESEARCH IS A JOURNEY NOT A QUICK FIX. SURVEY PLANNING AND INTERPRETATION AT THE HILLFORT IN GRĄBCZYN, POMERANIA, POLAND

Wroniecki, Piotr (Montefortino Prospection & Digitalisation) - Niedziółka, Kamil (Institute of Archaeology, University of Gdansk) - Marczewski, Maciej (Firma Archeologiczna Glesum)

Faced with the challenge of initiating a non-invasive survey in an area with little prior research, our team addressed key issues in archaeological exploration: selecting the right methods, deciding how to sample the site, and interpreting our results without jumping to conclusions or succumbing to aprioristic assumptions. Hillforts often lead to expectations of certain significant findings, which can shape our understanding of the data. However, each site, such as the Grąbczyn Hillfort in Pomerania, tells a unique story that may not align with common patterns.

This case study showcases the integrated, multidisciplinary approach that was applied to investigate the archaeological landscape, with a focus on Grąbczyn Hillfort. The study utilized non-invasive techniques such as magnetic gradiometry and GPR, while aerial prospecting with RTK UAV and UAV ALS/LiDAR provided high-resolution imagery for landscape study, documentation, and accurate terrain models. We will discuss how we developed an understanding of an archaeological site and its landscape through the systematic use of field techniques and the creation of interpretation strategies by merging established archaeological knowledge with field-collected data.

Since 2023, numerous test trenches have been laid out, guided by questions derived from the analysis of non-invasive datasets. These efforts aimed to investigate the origins of various anomalies, contributing valuable insights into the spatial layout of the Hillfort. However, the natural background limited the clarity of results, producing faint anomalies due to minimal contrast between the fill and surrounding soils. Despite these challenges, the findings were promising, revealing internal divisions within the hillfort and evidence of burning. While the new data resolved some existing questions and refined our understanding of the site, it also raised new inquiries that necessitate further investigation.

18 MINDING THE GAP BETWEEN GEOPHYSICAL DATA AND INTERPRETATION AT HISTRIA, ROMANIA

Rabinowitz, Adam (The University of Texas at Austin) - Neuhoff-Malorzo, Patricia (Independent Researcher)

Between 2018 and 2023, the Histria Multiscalar Archaeological Project (HMAP), a collaboration between the University of Texas at Austin and the Institute of Archaeology "Vasile Pârvan" in Bucharest, conducted a magnetometry survey of 4.5 hectares in the area of the site known as the "Plateau". The "Plateau" was part of the urban settlement from the late 7th century to the 1st century BCE, when it was occupied by residential and industrial structures. From the late 1st century CE forward, it became one of the city's extramural cemeteries. HMAP's magnetometry survey was designed to collect information about the urban infrastructure of the Greek period and to identify burials associated with the Roman period. Ground-truthing of the results showed that linear features with greater magnetism are roads constructed with large amphora fragments, while circular highly-magnetic features are pottery kilns. These results challenge assumptions that this part of the city had an orthogonal street grid in the Greek period and that ceramic production activity was confined to spaces along the city walls. More surprisingly, they confirm the accuracy of a previous magnetometry survey carried out in this area from 2000-2003, the results of which had long been considered to be problematic. The risks of overinterpretation are highlighted both by this situation and by our own attempts to classify buried features before ground-truthing. Test trenches revealed some anomalies we thought could be tombs to be ground-squirrel burrows and a modern archaeological dump, while other minor variations in the magnetic measurements were revealed as tombs only after excavation. More extensive excavations around features identified in the 2018 survey have also been crucial for the interpretation of the magnetometry results, while the combination of previous and current magnetometry surveys, together with drone-based photogrammetry, expand our ability to understand larger patterns of activity across the area.

19 ANALYSES OF CUCUTENI-TRYPILLIA SETTLEMENTS IN THE REPUBLIC OF MOLDOVA: INTEGRATION OF NON-INVASIVE, MINIMALLY INVASIVE AND INVASIVE INVESTIGATION METHODS

Schmauderer, Jessica (German Archaeological Institute, Romano-Germanic Commission; Friedrich-Alexander-University Erlangen-Nuremberg, Institute of Prehistory and Early History)

The Cucuteni-Trypillian culture (5200-3100 BC), spanning from the eastern Carpathians in Romania through the Republic of Moldova to Ukraine, has been the subject of extensive research since the 1960s. Multi-year research campaigns by the Romano-Germanic Commission of the German Archaeological Institute, initiated in 2007 in col-

laboration with international partners, have employed a comprehensive approach by combining noninvasive techniques with minimally invasive and invasive investigations.

The interdisciplinary approach made it possible to analyse settlement landscapes on a macro level, providing insights into settlement dynamics. To supplement the settlement landscape image of Cucuteni-Trypillia sites, aerial photographs from US spy satellites from the Cold War period were systematically examined. Suspicious areas were then investigated through a geomagnetic survey lasting several weeks. Settlements with promising magnetic images were analysed by core drilling to enable rapid interpretation and dating of the sites. This also served to verify the results from non-invasive methods.

Furthermore, a combination of diverse investigative methods was also used to analyse the Stolniceni 1 site at a micro level. Remote sensing and magnetic measurements identified over 1000 features. A combination of the evaluation of non-invasive investigations, core drilling and partial excavations was used to efficiently process these features, allowing a representative overview of the settlement to be obtained.

20 PRELIMINARY FINDINGS FROM NON-INVASIVE ARCHAEOLOGICAL INVESTIGATIONS IN SICILY, 2015-2022

Mozdziuch, Ewa (University of Opole) - Wroniecki, Piotr (Montefortino - Prospection & Digitalisation) - Mozdziuch, Sławomir (Institute of Archaeology and Ethnology Polish Academy of Sciences)

Between 2015 and 2022, the Centre for Late Antique and Early Medieval Studies at the Institute of Archaeology and Ethnology, Polish Academy of Sciences, undertook research in Sicily, focusing on the Norman influence on early medieval European culture. Through a combination of non-invasive techniques and targeted excavations, the project investigated two significant sites: the medieval monastery of Santa Maria di Campogrosso in Altavilla Milicia (north) and the Castello dei Tre Cantoni in Scicli (south). Utilizing advanced technologies including magnetometry, ground-penetrating radar (GPR), GPS RTK, and Lidar-equipped drones, the team uncovered previously unknown structures. These findings include a monastery building dating from the 12th to the 15th century in Altavilla Milicia, a 14th-century building workshop, and a segment of the 15th-century castle church of Santa Maria della Raccomandata in Scicli, previously known only from texts. All discoveries, initially made through non-invasive methods, were later verified by excavation, significantly contributing to our understanding of Norman architectural and cultural impacts in Sicily. The work was funded by research projects of the National Science Centre (NCN 2017/25/B/HS3/01699; NCN nr 2021/43/B/HS3/01988).

1112 THE DAY AFTER: THE MATERIALITY OF RESILIENCE, MEMORY AND INEQUALITY IN POST-DISASTER SCENARIOS

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Forlin, Paolo (University of Bologna; Northwestern University (USA)) - Gür, Selin (University of Bern) - Bognione, Marcella (University of Bern) - Cavalazzi, Marco (University of Bologna; University of Michigan) - Brown, Peter (Radboud University Nijmegen)

Session format: Regular session

Natural hazards are key agents in transforming landscapes, sometimes in largely irreversible ways. These significant episodes of environmental change can have profound repercussions for affected human societies across different timescales and spheres of life.

This session focuses on 'natural' disasters and aims to explore how catastrophes stimulated the transformation of cultural landscapes throughout the past. In so doing, the session seeks to shine new light on how human societies were impacted by natural hazards in different periods and cultural settings, and how they responded to short- and long-term consequences unleashed by these processes. Instead of simply examining 'continuity' and 'discontinuity', we seek to debate the materiality of resilience, adaptation, power, inequality, agency and memory in both pre- and post-disaster scenarios.

We invite contributions that reflect on the critical role played by disaster-affected societies in shaping cultural landscapes and ecologies. Disasters may be considered both windows of opportunity and stimuli for innovation but also manifestations of structural environmental injustice and catalysts for increasing social inequality. We also invite methodological papers that are more focused on the identification, assessment and dating of destructive events, or of post-disaster responses.

The session encourages theoretical and methodological papers focusing on European and Mediterranean case studies without chronological restrictions.

Session presenters will be invited to contribute to the publication of a special issue of *Quaternary Environments and Humans* which will be devoted to the archaeology of disasters.

ABSTRACTS

1 THE POLITICAL ECOLOGY OF A DISASTER: THE 1248 MONT GRANIER MEGA-LANDSLIDE REVISITED

Forlin, Paolo (University of Bologna; Northwestern University)

In November 1248, the failure of the northern cliff of the Mont Granier in Savoie (France) gave way to what was destined to represent the largest historic landslide in Europe. About 350 million cubic meters of debris collapsed into the valley floor, causing the disappearance of at least five settlements and irreversibly changing the landscape over 35 square kilometres. Rather than remaining an abandoned and desolated land, the boulder field which was since then called 'Les Abymes' soon became a stage for the elaboration of ecological and political strategies of 'recolonisation'. Landslide debris, buried villages, surviving churches, post-landslide lakes, political landmarks and a newly founded town are discussed to reflect on the feudal reshaping of such a 'wasteland'. In particular, my paper investigates the materiality of the post-disaster landscape and considers the archaeology of memory, inequality, and resilience from a political ecology perspective. This work draws on the EU-funded project 'WasteLands' which investigates post-disaster scenarios in medieval Europe.

2 WHAT MAKES A DISASTER DECISIVE? EVALUATING CAUSAL PATHWAYS IN POST-DISASTER SCENARIOS

Brown, Peter (Radboud University)

Natural disasters, including floods, droughts, and earthquakes, are often recognised as important events in the histories of regions, cities, and individual archaeological sites. The impact of such events on human populations, however, is often difficult to predict. Looking to the past, this paper attempts to understand why certain disasters seem to have resulted in major phases of cultural change while other, apparently similarly high-magnitude events, were apparently overcome without significant longer-term repercussions. At different moments in time, cultural, economic, political, and social developments overlapped to, at least partially, configure a society's capacity to respond against challenges imposed by a disaster. Wars, political turmoil, or economic problems, for example, often occurred in close association with natural disasters—at times magnifying their impact, reducing a society's ability to restore conditions to pre-event norms, or in some cases, as a result of the conditions created in a disaster's aftermath. This paper examines case study events from across the medieval world, using archaeological and historical evidence to explore the degree to which pre-event conditions combined with the 'moment(s) of disaster' shaped 'causal pathways' that, to some degree, pre-configured the impacts and outcomes of catastrophic events. Did more prepared, or 'resilient' societies, in which existing stressors—such as wars, sources of inequality, or political and economic problems—were relatively absent, overcome disasters with fewer longer-term impacts than those beset by existing exogenous and endogenous problems? While it is not always possible to offer definitive answers, medieval archaeological and historical evidence allows such questions to be explored in a way that is not possible for modern disasters, helping us to understand both the possible long-term impacts of these events as well as the factors which appear to have magnified or minimised their impacts on populations in the past.

3 WET FEET IN DUSTY RIVERS: THE RESILIENCE OF SOUTHERN MESOPOTAMIA'S HYDRO-CULTURAL LANDSCAPE

Borkowski, Sebastian (University of Bern)

The paper examines the resilience of the hydro-cultural landscape of Southern Mesopotamia to natural disasters in the context of political instability during the transition from the 3rd to the 2nd millennium BC.

In the 3rd millennium BC, the Mesopotamian alluvial plain was developed into a hydro-cultural landscape to support settlements and irrigation agriculture in an arid climate. To prevent catastrophic flood events and river avulsion, it was imperative to maintain levees and clean riverbeds. This is extensively documented in the administrative record of the Ur III period (c. 2112–2004 BC). However, the Sumerian City Laments, ideological literary compositions of the Isin-Larsa period (c. 2025–1763 BC), allude to the collapse of the hydro-cultural landscape and the subsequent deterioration of major cities following the decline of the Ur III state. In conclusion, the Sumerian City Laments celebrate the restoration of cities, with a special emphasis on the deeds of Išme-Dagan of Isin (c. 1955–1937 BC).

To challenge the validity behind the ideological message of the Sumerian City Laments, this paper presents an interdisciplinary and data-driven approach to holistically evaluate the medium-term resilience of the hydro-cultural landscape of Southern Mesopotamia to catastrophic flood events and river avulsion. The method used in this study combines a diachronic spatial analysis of settlement patterns and paleo-channels with a temporal network analysis of geographic information in the textual record of the late 3rd and early 2nd millennium BC.

4 **ASSESSING VULNERABILITY TO EXTREME EVENTS IN A FLOODPLAIN WITH HIGH RATES OF VERTICAL GROWTH: THE NORTHERN ROMAGNA REGION (ITALY)**

Cavalazzi, Marco (Università di Bologna; University of Michigan) - Abballe, Michele (Università Ca' Foscari Venezia) - Bortoluzzi, Daniele (Università di Milano) - Maranzana, Paolo (Boğaziçi University)

This paper investigates the response of local communities in the northern Romagna plain (north of Ravenna) to extreme events in the Late Antique and Medieval Periods (4th/5th - 15th centuries CE). Located in northeastern Italy, the northern Romagna plain poses a considerable challenge for archaeological research due to the considerable impact of geopedological biases, which stems from a high sedimentation rate caused by flooding and land reclamation. In particular, the region experienced extreme floods from the Apennine rivers, which, combined with a relevant subsidence rate, resulted in the deposition of thick alluvial layers that covered the more ancient archaeological layers.

These environmental factors have also been historically determinant, affecting human settlement patterns and landscape development, and they continue to do so today, as unpredictable extreme floods still impact life in this region.

With these premises in mind, this paper will discuss the research we conducted in this region employing a multiscale approach and crossing different methods of investigation, such as artefact survey, excavations, geoarchaeological investigations, and the analysis of written sources. The collected data shed light on the strategies adopted by local communities, particularly during the Late Antiquity and Middle Ages, to cope with extreme events and to adapt to a vulnerable and hazardous environment.

Thus, this paper provides new insights into the mechanisms of local socio-ecological systems in responding to extreme events while also addressing methodological challenges that are present in investigating these difficult “clay landscapes” (Mills and Palmer, 2007). Indeed, these landscapes were deeply affected by this kind of vulnerability as well as today are posing a significant challenge for archaeologists, due to their geopedological characteristics.

In this way, this research can assist local communities in developing a more conscious understanding of their historical relationship with past disasters, helping them address the contemporary challenges of landscape management.

5 **THE LATE MESOLITHIC STOREGGA TSUNAMI (CA. 6150 BCE): EXPLORING IMPACT AND POST-DISASTER RESPONSES**

Kilhavn, Havard (University of Stavanger)

To explore the impact of a tsunami that happened more than 8000 years ago upon a population of mobile hunter-gatherers is no easy task. However, since the discovery of the North Atlantic Storegga tsunami in the late 1980s, researchers have commonly assumed that the demographic consequences of the tsunami for Late Mesolithic coastal populations would have been catastrophic. For example, summed probability distribution modelling (SPD) of radiocarbon dates has previously been used as a proxy for exploring the demographic impact of the tsunami in north Britain. In conjunction with the 8200 cal. BP climatic cold event, the tsunami is here thought by some to have caused a Late Mesolithic “population collapse”.

To explore the impact and possible post-disaster responses of the tsunami, I approach this prehistoric disaster through complementary methodological approaches, taking both “top-down” and “bottom-up” perspectives. The top-down approach seeks to identify and assess the impact of the tsunami through an SPD-modelling of radiocarbon dates from the Atlantic coast of Norway. The results are used to question whether this method is suitable for exploring the demographic impact of the tsunami, which in turn has consequences for earlier claims of a “population collapse” caused by the tsunami. Late Mesolithic populations might have been more resilient in the face of a tsunami event than what is often assumed. By using a detailed numerical modelling of the tsunami, it is also possible to get a “bottom-up” perspective on how the tsunami could have been experienced by Mesolithic people on the ground, exemplified by the study of tsunami impact upon an island off the coast of South-Western Norway. Combined, the two approaches offer new insights into both the potential impact and post-disaster responses and scenarios in the wake of the largest tsunami ever recorded in the North Atlantic.

6 **CULTIVATING RESILIENCE: THE ROLE OF AGENCY AND MEMORY IN THE URBAN MARKET GARDEN 'BOOM' OF POST-EARTHQUAKE POMPEII (AD 62-79)**

Venner, Jessica (Institute of Classical Studies)

In AD 62, a major earthquake hit the town of Pompeii, causing extensive damage to its infrastructure. This natural disaster, coupled with a recent famine, meant that efforts to repair the town were slow. In addition, while the effects of the earthquake meant that most of Pompeii's population were faced with lifestyle challenges, such as displacement from demolished or damaged properties or food and water shortages others, namely the (wealthy) landed, were in a position to create opportunity from failure.

Between the AD 62 earthquake and the AD 79 eruption of Vesuvius, Pompeii witnessed a notable surge in market gardens within the city walls. Garden numbers increased by 280%, rising from an estimated total of 11 pre-earthquake to 42 post-earthquake. While some scholars have connected garden development to crisis response in Pompeii (Jashemski, 1977; Pesando, 2011; Esposito, 2018), a systematic quantification of the phenomenon has not been attempted, nor has the role of agency and memory in the phenomenon been explored.

This paper presents the first visual depiction of garden development in post-earthquake Pompeii. Guided by contemporary resilience and memory theory, it explores the pivotal role of the town's agricultural heritage in driving this transformative phenomenon. A close examination of the sites illustrates that this rapid growth was the result of diverse micro-actions implemented largely by the individual efforts of landowners and gardeners rather than state intervention. Motivated by economic incentives, and equipped with generational knowledge or ‘memory’, these grassroots initiatives inadvertently fostered a more resilient city poised to tackle future challenges, with positive implications for local food security, employment, income, and infrastructure. In addition to quantifying Pompeii's market gardens for the first time, this study aims to connect the town's cultural legacy to a flourishing market and provide a conclusive example of crisis-driven garden cultivation in antiquity.

7 **BEYOND THE SEISM. THE RESPONSE TO THE EARTHQUAKES IN THE NORTHERN AREA OF SICILY BETWEEN HISTORICAL AND ARCHAEOLOGICAL SOURCES**

Boglione, Marcella (University of Bern; École Pratiques des Hautes Études Paris)

Like today, in the past, earthquake disasters broke and overwhelmed daily relationships between people and community ties, and broke - perhaps even more severely than in the present - the residential roots of populations that often remained eradicated from their places sometimes forever.

Seismic disasters have always made people think, discuss, hypothesise: to understand how they happen, propagate, what damage they do, how one can defend oneself and how to react. Yet their effects, although they have been the subject of studies for centuries, are not known in widespread Italian culture. Even when, in relatively recent times, historical knowledge of seismic effects in the long term became an intrinsic part of scientific research, a conscious and shared memory of the danger was not created.

Sicily is one of the most seismically active regions in Italy in terms of earthquakes frequency and intensity. Just think of 11 January 1693 when the whole of Sicily was shaken by a very strong earthquake with a 7.4 magnitude. Known as the ‘Val di Noto earthquake’, the devastating quake destroyed more than 45 towns and caused at least 60,000 fatalities. The powerful tremors triggered a devastating tidal wave in the Ionian Sea, whose waves reached as far as Greece. Collapse and serious damage also occurred in Messina and in some towns on the north-eastern coast; injuries and partial collapse occurred in Palermo, Agrigento, Reggio Calabria and, more seriously, in Malta.

The paper aims to address the response to seismic and related events that occurred in the northern part of Sicily, from Trapani to Messina through the centuries, between the first millennium BCE and the first millennium CE in order to create a historical memory of the resilience of the population.

8 **FROM BAYRA TO VERA. THE COLLAPSE AND SUBSEQUENT RECONSTRUCTION OF A TOWN IN THE AFTERMATH OF AN EARTHQUAKE**

Alonso-Valladares, Moisés (University of Granada) - García Porras, Alberto (University of Granada)

On November 9th, 1518, an earthquake destroyed the town of Vera (Almería, Spain). Its inhabitants quickly organised the reconstruction, which involved abandoning the hill where the town was based and looking for a new settlement in the plain. The Andalusian town of Vera (formerly known as Bayra) would never recover from the strong tremor and the houses and buildings stayed buried.

It remained buried for over 500 years, until the spring of 2021, when the first archaeological campaign took place to evaluate the archaeological potential. Based on those excellent results, it was possible to launch a long-term project focused on the site and the consequences of the earthquake.

The dig brought out interesting findings, that allows us to reflect on the destruction and abandonment of the original settlement and the building of a new town involving deep changes within the population. In addition, the dig made possible to accurately document the 1518 earthquake and the response of the inhabitants of Vera, identifying the recovery of the houses and its later abandonment.

The practical implications of this process of resilience and change following a natural disaster, and the state led reconstruction of a town that involves some of the major figures of the early 16th century (Emperor Charles V, Pope Leo X, architect Francisco del Castillo) will be analysed in this work.

9 TRACING NATURAL CALAMITIES: LIPARI AS A CASE STUDY

Gür, Selin (University of Bern)

The Aeolian Islands are an archipelago of seven islands in the southern Tyrrhenian Sea, north of the Sicilian coast. They form a volcanic arc shaped by the Tindari Fault System. Lipari, also known as Meligunis in Greek, is the largest island in the archipelago. Systematic archaeological excavations have been ongoing in the Diana district since 1948. The region holds a history of uninterrupted settlement from the Bronze Age to the Roman Imperial Times. Notably, traces of sudden destruction in the 8th century BC offer strong evidence, leading to consideration of potential natural causes.

By combining modern geological data with archaeological methods, this ongoing research seeks to reconstruct the historical impact of natural calamities in Lipari. To gain a more holistic understanding of the dynamic interactions between human adaptation and the geological forces that have shaped the Aeolian Islands throughout history, the study aims to analyze whether architectural adaptations, such as structural reinforcement, were implemented as potential resilience strategies in response to calamities. The presentation will evaluate the current state of knowledge and archaeological data in the region, discussing the methodological approaches utilized in this research.

10 THE ARCHITECTURE IN RAW EARTH WITHIN THE GREEK COLONIES IN SICILY

Labartino, Davide (University of Bern)

The architecture in raw earth within the Greek colonies in Sicily constitutes a captivating field of study, often overlooked in scientific literature despite its historical and archaeological significance. This project aims to meticulously investigate the construction techniques, materials, cultural influences, and especially environmental factors shaping its evolution. It sheds light on how the Sicilian colonies were affected by natural disasters in different periods and cultural contexts, analyzing their short and long-term responses. The project focuses on the resilience, adaptation, and resistance of raw earth materials in pre- and post-disaster scenarios, employing a hands-on and interdisciplinary approach.

Research questions highlight nuances of this architectural form. Firstly, it explores predominant techniques in Greek, Phoenician-Carthaginian, and indigenous colonies in Sicily, seeking to identify construction methodologies through literature analysis and on-site inspections. For example, it would be interesting to investigate the colony of Himera in the area of the housing district, Selinunte in the area of the artisan district and the Phoenician-Carthaginian context of Mozia. Secondly, it delves into the contexts of applying these techniques, investigating material extraction locations and production sites. The core of the project examines the resilience of raw earth structures to natural disasters, particularly earthquakes (initially considering the context of Himera), identifying potential advantages and influencing factors. The methodology proposes innovative static and seismic tests, assessing the strength and response capabilities of raw earth structures to constant loads and seismic forces. Finally, it investigates cultural influences on raw earth architecture, aiming to identify the use of raw materials and cultural nuances in construction practices.

This underscores the importance of raw earth architecture as a forefront archaeological research field, offering new perspectives on techniques, materials, and socio-cultural and environmental contexts between the 8th and 5th centuries BCE.

11 BENEATH THE ASHES: ARCHAEOLOGICAL INSIGHTS ABOUT THE GREAT FIRE OF BUCHAREST

Motei, Raluca-Iuliana (Bucharest Municipality Museum) - Gavrilă, Elena (Bucharest Municipality Museum) - Pîrvulescu, Dan (Bucharest Municipality Museum)

Despite its destructive nature, fire served as a catalyst for change in 19th-century Bucharest, leading to the rejuvenation and reimagining of the urban landscape. While devastating, the significant fire provided local authorities with an opportunity to redesign and rebuild the city.

The Great Fire started on March 23rd 1847, the wind and flammable building materials fueled it for days, destroying a large area nowadays Historical Center of Bucharest, one of the most populated in the first half of the 19th century. Roughly 1,850 buildings were completely consumed by the fire, constituting one-fifth of the entire capital's structures at that time. In response, administrative and urban planning measures were implemented with the goal of minimizing the likelihood of a similar catastrophe happening again. These included the straightening and broadening of existing streets, as well the integration of more fire-resistant materials like brick or stone during the reconstruction phase.

Archaeological research frequently reveals elements that are less likely to have been documented in writing or can serve as a means to verify the accuracy of historical documents and visual representations. In the recent archaeological excavations conducted in the Historical Center, significant evidence of the destruction caused by the Great Fire and the subsequent extensive reconstruction efforts have come to light. Notably, visible traces of changes in the building alignment were uncovered, indicating a shift in the city's layout. Additionally, numerous cellars and subterranean infrastructure elements were integrated into the newly emerging cityscape. The results of archaeological excavations, when combined with historical records and visual representations, serve not only to authenticate the

extent of the destruction and subsequent reconstruction but also to offer valuable insights into the city's layout and architectural characteristics prior to the fire.

12 ECONOMIC AND SOCIAL TRANSFORMATION OF NEA PAPHOS (CYPRUS) AFTER THE 17/15 BCE EARTHQUAKE

Marzec, Edyta (Fitch Laboratory, British School at Athens; Institute of Mediterranean and Oriental Cultures, Polish Academy of Sciences) - Kajzer, Małgorzata (Institute of Archaeology and Ethnology of the Polish Academy of Sciences)

The search of earthquakes in archaeological and historical contexts has been the subject of multiple literary and archaeoseismic studies. To a great extent, research on this topic has so far focused on validating earthquake presence, and studies investigating their impacts on cultural landscapes are still rare. This is an effect of cautioning against overinterpreting the role of past disasters and the lack of a reliable methodological approach allowing for such interpretations.

Using the case study of Nea Paphos (southwest Cyprus), this pilot research project aims to investigate the economic and social consequences of its destruction by an earthquake in 17/15 BCE, followed by its extensive reconstruction with Imperial support. This research is utilising pottery pre- and post-dating the earthquake as a proxy to shed light on these enquiries, through an integrated macroscopic and laboratory analytical programme. The results suggested not only a change in pottery supply and consumption patterns but also a shift in the organisation of local manufacture, which caused an increased production of certain ceramic wares. It is possible that the influx of money from Rome created a high demand for labour and different types of ceramic material, which were essential during the phase of the city rebuilding. This paper is an important contribution to the way of approaching the economic, cultural and social transformations brought by catastrophes in antiquity.

1113 GOING BEYOND TRADITIONAL APPROACHES TO LITHIC RESEARCH IN PREHISTORY AND PROTOHISTORY: HYPOTHESIS, METHODS, VALIDATION, CONTRAST AND RAW DATA

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Abrunhosa, Ana (IPHES - CERCA - Institut Català de Paleoecologia Humana i Evolució Social; ICArEHB - Interdisciplinary Center for Archaeology and Evolution of Human Behaviour) - Vilmercati, Melissa (Sapienza, University of Rome - Department of Antiquities) - Prieto, Alejandro (University of the Basque Country UPV/EHU - Department of Geography, Prehistory and Archaeology) - Yeşilova, Görkem Cenk ((IPHES-CERCA) Institut Català de Paleoecologia Humana i Evolució Social; Universitat Rovira i Virgili, Dept. d'Història i Història de l'Art) - Sánchez de la Torre, Marta (Seminari d'Estudis i Recerques Prehistòriques (SERP); Institut d'Arqueologia de la Universitat de Barcelona)

Session format: Discussion session (with formal abstracts)

The study of stone raw materials and finished tools allows an understanding of the operational sequences, migration, trade, and socio-economic organisation of past human groups, particularly those belonging to Pre and Protohistory.

The determination of the origin of raw materials for tool making, and the selection of knappable materials, may give insight into the knowledge of the physical environment and settlement choices. Methods of analysis include macro and microscopic approaches, petrography, geochemistry, geoarchaeology, and mechanical properties definition. The study of reduction processes and/or manipulation through traditional techno-typological analysis coupled with specific approaches such as techno-economy, morpho-functional, production and use-wear traces, spatial analysis, statistics and archaeometry can lead to a more precise reconstruction of human behaviour. Although these different perspectives are traditionally studied independently as sub-fields of lithic studies, they are all interconnected. The availability of raw materials will determine choices and influence mobility patterns, while rock mechanical characteristics have direct implications for technological behavior and the technical and cultural adaptation of material culture. However, methods and procedures still largely vary between research teams and the communication between scholars from different regions and chronological research periods can become a challenge to effectively share, compare, and interconnect information from all these methodologies and approaches.

In this session, we invite researchers working on the multifaceted methodologies of stone research applied to Pre and Protohistory, from the survey and sampling of reference materials to the characterisation of the rocks and tools. The aim is to discuss methodological developments and approaches in stone research, data comparability, comprehend the current state of the art in lithic research and consider prospects in the field. We also welcome the formulation of standard protocols and the creation of frames of reference for raw data availability.

1 OLD AND NEW METHODOLOGICAL APPROACHES APPLIED IN BRONZE AGE LITHICS STUDIES: THE CASE OF COPPA NEVIGATA (SOUTHEASTERN ITALY)

Vilmercati, Melissa (Sapienza, University of Rome - Department of Antiquities)

The production and use of stone tools remained a common and reiterated activity throughout the Bronze Age, even though the archaeological research continues to consider this category of artifacts as secondary during such period. Because of this bias, there are still few studies on this topic, and, especially in Italy, they almost never go beyond the traditional typological issues.

The current paper aims to overcome this outdated preconception, pushing forward the study of the Italian Bronze Age lithic artefacts. The chosen case-study is the fortified settlement of Coppa Nevigata, one of the most extensively excavated archaeological contexts of the Italian Bronze Age. Because of its long occupation – throughout the entire Bronze Age till the beginning of the Iron Age (18th-8th century BCE) – it allows to answer in diachronic terms to specific questions about the production and use of stone tools.

This presentation will focus on the description of the integrated and multilevel protocol used in the study of the lithic assemblage from the site. The methodological procedure began with a classical techno-typological analysis and progressed through a morpho-functional approach combined with targeted experiments and statistics, and finally arrived at the use-wear study. This integrated analysis enabled the reconstruction of the aspects related to both the operational chain used in the settlement and the functions of the produced stone tools.

Because of its exhaustiveness, this method goes beyond the traditional approach used in the study of Bronze Age lithics, proving to be extremely useful for the understanding of the techno-morphological and functional issues related to stone knapping expertise. As a result, it can serve as a standardized protocol for analysing and compare lithic assemblages of other coeval contexts.

2 THE QUARTZITE AND QUARTZ LITHOTHEQUE FROM THE CENIEH: SEARCHING FOR RELIABLE, COMPARABLE AND ACCESSIBLE RAW MATERIAL DESCRIPTIONS

Prieto, Alejandro (Department of Geography, Archaeology and Prehistory, University of the Basque Country) - Cristóbal, Paula (Department of History, Geography and Communication, University of Burgos) - Llamazares González, Javier (Experimental Archaeology and Taphonomy Laboratory, CENIEH) - Cuartero, Felipe (ERC-MULTIPALEOIBERIA-StG, Department of History and Philosophy, University of Alcalá)

Raw material studies have been mainly focussed on tracing the origin of the rock artefacts discovered in archaeological sites. The distance in which a resource is separated from its geological source means the distance that humans moved or exchanged a particular material. This allowed the prehistorian to infer the extension of economic human territories, determine prehistoric migrations, or measure the significance of the social and interchange networks in the Prehistory. Furthermore, the characterisation of these rocks is allowing the understanding of the contexts where rocks were procured, the potential selective mechanism to obtain them, and even the reasons behind its exploitation.

How are we characterising these rocks? How should we describe them to make reliable descriptions? Should we need frames of reference to compare rock descriptions? And how are we sharing the knowledge we are producing?

In this talk, we are going to address these questions by the presentation of the quartzite and quartz lithotheque from the CENIEH. This collection is made of 73 samples that have been petrographically described through their thin sections and their surfaces, combining destructive and high-resolution techniques with non-destructive ones. The wide geographic and geological variety of the stored samples and the absence of a particular hypothesis to address when analysing the materials have challenged the description of the samples and have made us think over the aforementioned questions. In this presentation, we will show the collection and how their samples were characterised through the petrogenesis of the material. We will also think about the concepts of reliability, comparability and accessibility in lithic raw material characterisation and how they have been addressed in the study of this collection.

3 LOW AND HIGH MAGNIFICATION APPROACHES TO THE BIPOLAR TECHNIQUE: CONTROLLED EXPERIMENTAL GROUPS AND THE SITE OF LA CANSALADETA

Yesilova, Gökem (Institut Català de Paleoeologia Humana i Evolució Social; Universitat Rovira i Virgili, Dept. d'Història i Història de l'Art) - Ollé, Andreu (Institut Català de Paleoeologia Humana i Evolució Social; Universitat Rovira i Virgili, Dept. d'Història i Història de l'Art)

The bipolar technique represents a flaking strategy that endured from 3.3 million years ago until the 20th century, demonstrating a non-uniform geographical or chronological distribution. This method entails the deliberate applica-

tion of an active percussive element onto a core situated upon an anvil, thereby effecting intentional contact for the purpose of flake removal.

The challenge of discerning this technique in archaeological materials, notwithstanding its distinct fracture mechanism compared to freehand flaking, is a widely acknowledged aspect among researchers specializing in this field. From a macroscopic standpoint, the conducted research has proven instructive in delineating and interpreting the most characteristic features of this technique. Nevertheless, microscopic studies are poised to assume a distinct role in the interpretation and description of subtle macroscopic differences associated with this technique.

In this study, we investigate the technological indicators of the bipolar technique from a microscopic perspective, employing both low and high magnification approaches within a controlled experimental group comprising various raw material types. Our examination encompasses the identification and interpretation of the microscopic technological indicators of this technique in archaeological material. To achieve this, we compare the results of our experiment with those derived from the comprehensive analysis of refit sets identified during the technological study of the La Cansaladeta site (Middle Pleistocene), situated in northeastern Spain.

4 EXPLORING KNAPPING TECHNIQUES THROUGH 3D MICROSCOPY: PRELIMINARY RESULTS AND METHODOLOGICAL INSIGHTS

García-Natale, Martín Julio (Universidad Autónoma de Madrid, Departamento de Arqueología y Prehistoria) - Torres Navas, Concepción (Instituto de Historia, CSIC- Spanish National Research Council, Madrid, Spain,) - Baena-Preysler, Javier (Universidad Autónoma de Madrid, Departamento de Arqueología y Prehistoria)

Identifying knapping techniques is one of the most researched topics regarding the study of lithic remains left by our ancestors. Many approaches have tried to split hairs on how stone tools were produced. Qualitative ones have mostly been preferred, attending to the identification of characteristic stigmata produced by different knapping techniques. However, this type of approach has sometimes been too dependent on the experience and the understanding of the lithics by the researcher.

During the last few years, 3D analysis adapted to lithic studies has helped to homogenize and standardize data used to study the way stone tools were made. 3D microscopy, however, has been set aside for its use in traceological studies even though its potential on providing both quantitative and fine-grained qualitative data.

Here, we present some preliminary and encouraging results on the use of 3D microscopy for identifying knapping techniques. We focus on a specific methodology that provides quantitative and qualitative data that may be able to discriminate different knapping techniques through the development of an experimental protocol for providing specific replicas analyzed, as well as its comparison with archaeological lithic remains. We are confident that this methodology will provide more accurate results and help us understand the way our ancestors culturally evolved on the way they made their tools.

5 BEYOND TYPOLOGY - TOWARD A COMPUTER-AIDED DIACHRONIC ANALYSIS OF VARIABILITY IN LITHIC PROJECTILE MORPHOLOGY

John, Robin (Department of Prehistoric Archaeology, University of Cologne; Stiftung Neanderthal Museum) - Hussain, Shumon T. (Centre for Multidisciplinary Environmental Studies in the Humanities (MESH), University of Cologne; Department of Prehistoric Archaeology, University of Cologne) - Maier, Andreas (Department of Prehistoric Archaeology, University of Cologne)

Traditionally, lithic industrial variability in the archaeological record has been described mostly in typological terms. While typologies have a long history in Palaeolithic archaeology and can capture morphological diversity in various stone artefacts comparatively well, lithic artefact variability, i.e., the differences in shape and size within a single type, is only insufficiently reflected. To overcome this inherent problem of typologies, PyREnArA (Python-R-Environment for Artefact Analysis), a semi-automatic system for recording and quantitatively analysing morphometric data of lithic tools, was developed and progressively refined over the last couple of years. Instead of taking individual measurements on a single artefact after another and subsequently feeding these data into special computer programs for statistical analysis – a process both error-prone and time-consuming – we integrated these steps into a single implementation. Starting with a standardised way of orientating multiple artefacts on one image and afterwards recording standard properties, such as size, shape, or the position of modifications on each artefact, PyREnArA also records properties which are more difficult to measure manually, such as an artefact's surface area or the position of the centre of mass. These data can easily be fed into a variety of build-in quantitative methods like Geometric Morphometrics (GMM) or Redundancy Analysis (RDA). Combined with chronological information on the analysed artefacts, the latter may detect diachronic variability related to evolutionary processes. The degree of standardisation and variability within individual assemblages or larger geographic regions can also be calculated, visualized and compared. In this talk we apply our method to a subset of a dataset compiled for an ongoing PhD project (RJ) conducted at the Neanderthal

Museum and the University of Cologne, dealing with diachronic trends captured by the morphology of Upper and Late Palaeolithic shouldered points from across Europe.

6 "CHOCOLATE FLINT" – TWO SOURCE AREAS AND HOW TO DISTINGUISH THEM THROUGH ADVANCED PETRO-GEOCHEMICAL METHODS

Mandera, Sara (Institute of Archaeology, Nicolaus Copernicus University, Toruń, Poland) - Brandl, Michael (Austrian Archaeological Institute, Austrian Academy of Sciences, Vienna, Austria) - Sudoł-Procyk, Magdalena (Institute of Archaeology, Nicolaus Copernicus University, Toruń, Poland) - Hauzenberger, Christoph A. (Institute of Earth Sciences - NAWI Graz Geocenter Petrology & Geochemistry, Karl-Franzens-University Graz, Austria) - Werra, Dagmara H. (Institute of Archaeology and Ethnology, Polish Academy of Sciences, Warsaw, Poland) - Kerner-Gubała, Katarzyna (Institute of Archaeology and Ethnology, Polish Academy of Sciences, Warsaw, Poland) - Boroń, Tomasz (Institute of Archaeology and Ethnology, Polish Academy of Sciences, Warsaw, Poland) - Krajcarz, Maciej T. (Institute of Geological Sciences, Polish Academy of Sciences, Warszawa, Poland)

"Chocolate flint" is a siliceous raw material well known from the Holy Cross Mountains (HCM) in south-central Poland, which was of great importance in the Late Palaeolithic and Mesolithic economies. Only recently, previously unknown deposits have been discovered in the Kraków-Częstochowa Upland (KCU). This finding has challenged the previous notion of one singular source area of this raw material for chipped stone production and, consequently, our understanding of the lithic economy in east-central Europe. It is now clear that this more complex source situation and the associated networks of agents involved in the distribution of "chocolate flint" require a revision of assumed distribution patterns.

This study presents the first results of the ongoing multidisciplinary research endeavours to characterise the material and trace the distribution of artefacts made from "chocolate flint" within KCU and beyond. The primary goal of our provenance analyses is to differentiate this material from "chocolate flint" originating in the HCM. Our study involves petrography, microfacies analysis, geochemistry applying Laser Ablation ICP-MS and spectroscopic techniques such as FTIR (Fourier Transform Infrared Spectroscopy).

The research was funded by the National Science Center, Poland (grants: 2018/30/E/HS3/00567, 2011/03/N/HS3/03973, 2015/17/N/HS3/01279, and 2017/25/B/HS3/01224) and by the Nicolaus Copernicus University in Toruń within the program Excellence Initiative – Research University (grant 4101.00000070, 03.01.00003785).

7 A STANDARDISE APPROACH TO STUDY SURVEY LITHICS: THE NEW ASSEMBLAGES FROM THE LEBANESE-ITALIAN ARCHAEOLOGICAL PROJECT IN THE REGION OF TYRE

Bucci Casari, Francesco (Department of Ancient World Studies, University of Rome "La Sapienza") - Fusco, Marianna (Department of Ancient World Studies, University of Rome "La Sapienza"; Department of History and History of Art, University Rovira "I Virgili") - De Paolis, Paolo (Department of Ancient World Studies, University of Rome "La Sapienza") - Spinapolic, Enza (Department of Ancient World Studies, University of Rome "La Sapienza") - D'Andrea, Marta (Department of Ancient World Studies, University of Rome "La Sapienza") - Haider, May (Lebanese-University) - Badawi, Ali (Directorate-General of Antiquities)

The survey materials represent a valid element for indicate the presence of past human occupations. This is particularly relevant in areas or zones where no archaeological presence is reported in the general literature.

Although they do not provide an absolute chronological framework, surface collection is useful as a first step for the investigation of large, unrecorded areas.

Since 2019, the Lebanese-Italian Archaeological Project in the region of Tyre, combining pedestrian surveys and stratigraphic sondages, aims at reconstructing human activities and settlement patterns in the regions of Shawakeer and Ras el-Ain. In the framework of this project, a large number of lithic artifacts was collected from surface, documenting human activities in the project's area since the Palaeolithic Period. This is a substantial advancement in the scholarly knowledge of the region, because Tyre is not currently charted on maps for this period. This data represented a methodological challenge for the classification of lithic industries and the association with a specific techno-cultural complex. Thus, a traditional descriptive methodology was adopted, with qualitative analysis where possible, in order to understand the occupation timeframe of the region.

The classification and technological analysis of the lithic industries, together with the analysis of the spatial distribution of the artifacts, facilitated the development of a diachronic chronological framework for the area, showing the presence of lithic technologies spanning from the Lower Palaeolithic to the Bronze Age, through the creation of databases and their management in a GIS environment. The application of this traditional methodology has effectively facilitated the examination of a substantial quantity of lithic artifacts. Together with the analysis of the chaînes opératoires for the reconstruction of the reduction systems, whenever applicable, this method has allowed us to establish a preliminary relative chronology of the artifacts within the assemblages from Shawakeer and Ras el-Ain.

8 REVISITING THE MIDDLE PALAEOOLITHIC SITE OF RAS EL-KELB, LEBANON: A COMPREHENSIVE ANALYSIS OF LITHICS AND RAW MATERIAL

Soubra, Marya (Paleoanthropology, Senckenberg Centre for Human Evolution and Palaeoenvironment, Institute of Archaeological Sciences, University of Tübingen, Germany) - Hilbert, Yamandu (Paleoanthropology, Senckenberg Centre for Human Evolution and Palaeoenvironment, Institute of Archaeological Sciences, University of Tübingen, Germany) - El Zaatari, Sireen (Paleoanthropology, Senckenberg Centre for Human Evolution and Palaeoenvironment, Institute of Archaeological Sciences, University of Tübingen, Germany)

The Middle Palaeolithic site of Ras el-Kelb, excavated in the 1950s by Dorothy Garrod and Germaine Henri-Martin, remains a significant yet underexplored archaeological site in terms of modern archaeological methodologies and technological advancements. In this study, we conduct a comprehensive re-evaluation of 200 lithic artefacts from the original collection, employing new methodologies and scientific technologies. The analysis includes various artefact types, such as cores, flakes, blades, Levallois products, scrapers, and retouched pieces. Our primary objective is to refine the data concerning composition, function, and production techniques of the lithic assemblage. To achieve this, we employ qualitative and quantitative analyses, alongside low-power and high-power approaches for traceological analysis. Furthermore, we address the neglected aspect of local raw materials, aiming to provide insights into the procurement, utilization, and exploitation strategies by the Middle Palaeolithic population of the Lebanese coast. Our results indicate that the lithics from Ras el-Kelb were primarily utilized for diverse cutting and scraping tasks, suggesting a domestic character for the site's activities. In addition, our understanding of Ras el-Kelb's significance within the Middle Palaeolithic landscape is enhanced by contextualizing our findings within a broader geographic and chronological framework.

9 LITHIC RAW MATERIAL SUPPLY AT THE MIDDLE PALEOLITHIC SITE OF LOS ALJEZARES: GEOLOGICAL AND GEOMORPHOLOGICAL CONSTRAINTS

Chazarra, Nahum (Universidad de Valencia) - González, Jaime (University of Alicante) - Canseco, Davinia (University of Alicante) - Alfaro, Álvaro (University of Valencia) - Villaverde, Valentín (University of Valencia) - Eixea, Aleix (University of Valencia)

Los Aljezares represents one of the few Middle Palaeolithic open-air sites in the Iberian Peninsula. A U/Th age (132 ± 10 ka) from associated carbonate deposits allows us to attribute the site to the uppermost part of the Upper Pleistocene (MIS 5). To date, a total of two levels of human occupation have been identified in which the density of lithic remains is low compared with cave and rock shelter sites in the region. In this paper we present the first lithic raw material analysis and their catchment areas using the latest geological and geomorphological data available that take into account the evolution of the landscape, which in this area has been very fast due to factors like active tectonics and eustatic changes. New survey works were developed in the surrounding area, where some Upper Palaeolithic sites—such as Ratlla del Bubo o Cova del Sol—are located. These works allow us to characterise the different lithologies documented in the archaeological assemblage from a macro (colour, texture and appearance) and microscopic (thin sections that allow us to determine its mineralogy, inclusions, and fossils to assign the raw materials typology) point of view. With this information, we compare the different strategies used by hunter-gatherer groups from the Middle and Upper Palaeolithic in the central Mediterranean region of the Iberian Peninsula.

10 TECHNO-FUNCTIONAL ANALYSIS OF THE MOUSTERIAN LITHIC ASSEMBLAGE FROM GABASA CAVE (SPAIN)

Shveygert, Ekaterina (Universidad de Zaragoza; Instituto Universitario de Investigación en Ciencias Ambientales de Aragón (IUCA) de la Universidad de Zaragoza; Grupo de Investigación Primeros pobladores y patrimonio arqueológico del Valle del Ebro (P3A)) - López-Tascón, Cristina (Universidad de Zaragoza; Universidad de Oviedo; Instituto Universitario de Investigación en Ciencias Ambientales de Aragón (IUCA) de la Universidad de Zaragoza; Grupo de Investigación acreditado LANDS, Universidad de Oviedo)

Beyond the traditional descriptive typological methods, many archaeological techniques are currently developed to expand the boundaries of our knowledge of prehistoric societies. Thus, the techno-functional analysis applied to the study of lithic collections allows us not only to recognize the production of industries, but also their management and the possible specialised use of the tools.

The presentation focuses on the analysis of three selected lithic assemblages (d, f, and g archaeological levels) from the Middle Palaeolithic site named "Cueva de Los Moros I of Gabasa" located in the foothills of the southern slope of the Pyrenees (Huesca, Spain). A first technological study has been carried out on the three entire lithic assemblages, followed by the use-wear analysis of a selected sample from each level.

The present study aims, firstly, to both reconstruct the technological operational chains and identify the functionality of the lithic material, thus complementing existing data on the functional interpretation of the site. Secondly, we seek

to compare the different occupational stages of the cave, in order to understand and reconstruct its evolutionary process over time.

11 QUARTZ AND QUARTZITE IN A FLINT-BASED ASSEMBLAGE: THE CASE OF ABRI DU MARAS

Abrunhosa, Ana (IPHES-CERCA - Institut Català de Paleoeologia Humana i Evolució Social, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Tarragona, Spain; ICArEHB - Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, FCHS - Universidade do Algarve, Portugal.) - Chacón, María Gema (IPHES-CERCA - Institut Català de Paleoeologia Humana i Evolució Social, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Tarragona, Spain; UMR7194 - HNHP (MNHN - CNRS - UPVD - Sorbonne Universités), Paris, France) - Moncel, Marie-Hélène (UMR7194 - HNHP (MNHN - CNRS - UPVD - Sorbonne Universités), Paris, France)

Raw material studies have conventionally centred on flint and obsidian to decode long-range mobility patterns. Nevertheless, recent methodologies have broadened the scope and acknowledged that other raw materials can be proxies for understanding various facets of human behaviour. On the other hand, local resources, their characterisation, and categorisation can be relevant in comprehending the factors influencing the exploitation of specific materials, the extent of material diversity explored, the technical and cultural reasons behind such choices, and the implications for site selection and temporality of occupation.

The Abri du Maras, located close to the Ardèche River's margins, a Rhône River tributary, is a Middle Palaeolithic site occupied by Neanderthal groups between MIS 7 and MIS 3 with a flint-based lithic assemblage. While the origin and procurement distances of flint have been relatively well-documented, the assemblage also includes a notable albeit previously overlooked proportion of quartz and quartzite. These materials, likely sourced locally, were often sidelined in research, a common occurrence in flint-dominated contexts.

The 'Quartz and Quartzite Neanderthal Assemblages of Payre and Abri du Maras' project, conducted under the MSCA CoFund fellowship at IPHES and MNHN (France), seeks to investigate the presence of these materials and understand the economic dynamics of lithic resource procurement and management at the local level.

The archaeological assemblage comprising 196 pieces from levels 4 to 6 of Abri du Maras and 858 from Payre levels D, F and G were characterised macro and microscopically based on geological criteria. The availability of local raw materials was defined through the study of cartography, survey and sample collection on the ancient terraces of the Ardèche River and its current banks.

Through this project, we aim to comprehend the significance of studying quartz and quartzite materials and present the latest findings and interpretations regarding their role in past human behaviour.

12 LITHOLOGICAL CHARACTERISATION OF RAW MATERIALS FROM SUB-UNIT IIIb OF TEIXONERES CAVE: A MULTIDISCIPLINARY APPROACH

Muñoz del Pozo, Alicia (Universidad de Zaragoza (UNIZAR). Departamento de Ciencias de la Tierra. C/ Pedro Cerbuna 12. 50009 - Zaragoza, Spain.; Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Gómez de Soler, Bruno (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Chacón, María Gema (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.; UMR7194-HNHP (MNHN-CNRS-UPVD-Sorbonne Universités), Musée de l'Homme, 17 Place du Trocadero, 75116, Paris, France) - Picin, Andrea (Alma Mater Studiorum-Università di Bologna, Dipartimento di Chimica "G. Ciamician", via Selmi 2, 40126 Bologna, Italy.) - Bustos-Pérez, Guillermo (Universidad Autónoma de Madrid (UAM). Departamento de Prehistoria y Arqueología. Facultad de Filosofía y Letras. Campus Cantoblanco, 28049 Madrid, Spain.; Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Blasco, Ruth (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Rivals, Florent (ICREA, Pg Lluís Companys 23, 08010 Barcelona, Spain.; Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.) - Rufà, Anna (ICArEHB - Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, Universidade do Algarve, Campus de Gambelas 8005-139 Faro, Portugal.; Univ. Bordeaux, CNRS, MCC, PACEA, UMR 5199, F-33600 Pessac, France.) - Rosell, Jordi (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA), Zona Educacional 4, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain.; Universitat Rovira i Virgili (URV), Departament d'Història i Història de l'Art, Avinguda de Catalunya 35, 43002 Tarragona, Spain.)

Teixoneres Cave (Moià, Barcelona) is part of the Toll Cave karstic system formed within Neogene limestones of Collsuspina formation. Filled with Pleistocene sediments dating approximately between 200 and 16 kya BP. The lithic industry in sub-unit IIIb (MIS 3) is formed by 5083 items, primarily composed of quartz, followed in abundance by chert, limestones, quartzites, hornfels, and sandstones.

This research focuses on examining the various lithologies comprising the lithic assemblage and the distinctive features that characterise each type of rock through macroscopic and microscopic analyses. Each lithology corresponds to a rock type with different geological origins, thus requiring different methodologies for each of them.

Quartz (n=2998) originates from conglomerates 5 km south of the site. Criteria such as colour, crystalline habit, and impurities are used for identification. Chert (n=1550) is mainly located 10 km to the east. Attributes considered include colour, texture, diaphaneity, inclusions, and features of its bedrock (fossils, crystal shapes). Limestone (n=125) texture is identified following the classification system proposed by Dunham (1962), along with the presence or absence of fossils. Quartzite (n=72) and hornfels (n=68) are analyzed to recognize the minerals associations present, as well as their size, crystalline habit, and type of contact between crystals. Sandstone (n=48) are classified based on clast size, matrix and cement percentage, and mineralogy. All these raw materials come from the fluvial courses near the site.

To gain a more precise understanding of the procurement areas and mobility patterns of the Neanderthals inhabiting Teixoneres Cave, it is crucial to consider the diverse analytical approaches required for each item based on its lithology.

The aim of this paper is to provide a comprehensive characterisation of the lithic assemblage from sub-unit IIIb of Teixoneres cave and to discuss the optimal criteria and approaches for characterising each type of lithology represented at the site.

13 NEW DIRECTIONS IN CHERT PROVENANCE: TOWARDS NEW BASIS FOR DETECTING MOBILITY AND TERRITORIAL BEHAVIOUR IN CENTRAL ITALY DURING PREHISTORY

Carletti, Elena (Sapienza University of Rome) - Eramo, Giacomo (University of Bari) - Cardarelli, Lorenzo (Sapienza University of Rome; CNR, Istituto di Scienze del Patrimonio Culturale, Area della Ricerca Roma 1) - Forti, Luca (University of Milan) - Allegretta, Ignazio (University of Salento) - Monno, Alessandro (University of Bari) - Conati Barbaro, Cecilia (Sapienza University of Rome)

New methods for lithic research are rapidly increasing among the scientific community, going far beyond the traditional techno-typological approach. Updated methodologies applied to the material culture can, indeed, deepen our understanding of past communities, enlightening the multifaceted spectra of human behaviour, otherwise unrevealed.

In this work, we will discuss the role of chert as a proxy for tracing provenance and the past human movement, according to a multi-scalar approach. In fact, the identification of the geographic origin of the knapped lithic raw material can offer a fresh perspective into mobility, territorial behaviour, and resource management.

In this talk, we will present the preliminary data obtained from the non-destructive provenance analyses applied to the Middle Palaeolithic assemblage from Grotta Battifratra (Sabina region, central Italy). Specifically, we will discuss about:

1. The creation of a new chert reference collection, currently lacking for the area;
2. The non-destructive chert characterization protocol (NM-PCI) of the assemblage, including petrographic and geochemical criteria;
3. A new statistical approach, developed to process the resulting multiple dataset.

The results obtained will clear the catchment area of the human groups occupying Grotta Battifratra rock-shelter during the Middle Palaeolithic, highlighting their routes to the knappable raw material. At the same time, the new geological reference collection will shed light on the availability and distribution of chert through the area and serve as a fundamental tool to perform provenance analysis in central Italy, encouraging future directions and developments.

14 ESTABLISHING EXPERIMENTAL BASELINES TO INTERPRET LOW-COST TECHNOLOGICAL BEHAVIOR DURING THE MIDDLE TO UPPER PALEOLITHIC TRANSITION IN SOUTHERN IBERIA

Ferar, Nolan (Interdisciplinary Center for Archaeology and the Evolution of Human Behaviour (ICArEHB), Universidade do Algarve, Faro, Portugal) - Reeves, Jonathan (Technological Primates Research Group, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Center for the Advanced Study of Human Paleobiology, Department of Anthropology, The George Washington University, Washington, DC, USA) - Moore, Mark (Archaeology and Palaeoanthropology, University of New England, Armidale, New South Wales, Australia) - Cascalheira, João (Interdisciplinary Center for Archaeology and the Evolution of Human Behaviour (ICArEHB), Universidade do Algarve, Faro, Portugal)

Reconstructions of population dynamics during the Middle to Upper Paleolithic transition in southern Iberia are currently based on inferences linking lithic assemblages to cultural technocomplexes to genetically distinct populations. The Iberian Middle Paleolithic is characterized by the prevalence of low-cost, expedient reduction strategies. Thus, assemblages dating to this period that are relatively simple technologically and lacking diagnostic Upper Paleolithic elements are commonly taken as evidence of late Neanderthal survival. Often comprised of “low quality” raw materials, especially quartzite and quartz, these assemblages are sometimes small, including few formal tools and cores. Given low-cost core reduction strategies are widespread throughout hominin evolution, the diagnostic status of such assemblages may be questioned. On the other hand, the variability and patterning within and between expediently produced assemblages remains relatively underexplored relative to that of higher-cost technological products—and their interpretive potential is therefore potentially untapped.

Experimental ‘baseline studies’ provide an informative starting point from which to explore the variability and patterning arising from expedient technological behavior, and ultimately to inform our interpretation of archaeological patterning. Following a protocol developed by Moore and Perston, quartzite and quartz cobbles are reduced at random. Properties of the resulting flakes and cores are recorded across the reduction sequence. The variability observed is considered a proxy for maximally expedient core reduction. For comparison, experimental samples of intentional discoidal and Levallois reduction are produced on the same raw materials. Machine learning can be used to explore to what extent, and via what properties, these reduction strategies can be reconstructed from their products. The impact of sample size and bias, realities in the archaeological record, is further explored by applying the trained algorithm to subsets of the overall dataset.

15 EXPLORING THE FACIES CONVERGENCE IN EVAPORITIC CHERTS FOR COMPREHENSIVE CHARACTERIZATION

Gómez de Soler, Bruno (Institut Català de Paleoecologia Humana i Evolució Social (IPHES-CERCA); Universitat Rovira i Virgili (URV)) - Burton, Evie (Irish Centre for Research in Applied Geosciences (iCRAG); School of Earth Sciences, University College Dublin (UCD)) - Rodríguez-Salgado, Pablo (Irish Centre for Research in Applied Geosciences (iCRAG); School of Earth Sciences, University College Dublin (UCD)) - Bria, Judit (Institut Català de Paleoecologia Humana i Evolució Social (IPHES-CERCA); Universitat Rovira i Virgili (URV)) - Menuge, Julian (Irish Centre for Research in Applied Geosciences (iCRAG); School of Earth Sciences, University College Dublin (UCD))

In the Northeast of the Iberian Peninsula, in the central Catalan region, the main geological formations housing chert are the evaporitic formations of the Paleogene marginal basins of the Ebro Depression. Their formation environment corresponds to shallow saline lakes, where depending on their location (center or margin of the lake) and phase (dilution, concentration, exposure), the surrounding lithology varies, causing differences in the attributes that characterise each of these cherts.

From a petrographic perspective, Cenozoic cherts from evaporitic environments are characterised by their great heterogeneity, which in many cases makes any further characterisation and assignment a challenging task. The use of complementary geochemical techniques such as X-ray fluorescence can help better control this variability.

The abundance of prehistoric archaeological sites in this region, where hunter-gatherers used this raw material to make their artifacts, necessitates the use of analytical techniques by archaeologists to reliably characterize the material. Due to its non-destructive nature, easy handling and data acquisition, and the possibility of obtaining a large amount of data in a relatively short period, X-ray fluorescence becomes a very interesting technique for archaeological discipline.

In this paper, we present the characterisation of six geological formations, corresponding to four evaporitic formations (Valldeperes fm., St. Genis fm., Pira fm. and Rauric fm.), a lacustrine marshland (Bosc d'en Borrás fm.), and a lacustrine formation (Montmaneu fm.). With over 40 outcrops and 450 samples analysed, our aim is to discern the convergence of facies, and assign archaeological assemblages of many sites of the region (e.g., Abric Romani, Cova de les Teixoneres, among others) to specific geological formations and its possible outcrop. This will allow us to establish procurement areas and, consequently, insights into mobility patterns.

16 TRANSFORMATION OF MICROLITHS DURING THE EARLY NEOLITHIC IN THE NEAR EAST: THE CASE STUDY ON GRE FILLA IN UPPER MESOPOTAMIA

Agirsoy, Zeynep Beyza (Ankara University, Department of Prehistory)

Microlith tools are small, thin, geometrically, and non-geometrically shaped tools used by people throughout prehistoric times in their daily lives, such as hunting and fishing. This study analyses the examples discovered in Gre Filla in order to understand how microlithic tools transformed/evolved/diversified throughout the phases of the Early Neolithic (Pre-Pottery Neolithic).

Gre Filla stands as a settlement in the Near East, providing recently acquired data on the Early Neolithic. Excavations conducted between 2018 and 2022 at Gre Filla, situated in the Diyarbakır province of Turkey, within the hypothetical boundaries of Upper Mesopotamia, unveiled a continuous archaeological deposit dating back to the Early Neolithic. Microliths, constituting 4% of the tools recovered from the Early Neolithic levels of Gre Filla, were primarily produced from obsidian raw material. The diverse techno-typological characteristics of these microliths can be attributed to settlement phases, period-specific phenomena, changes in hunting and fishing methods, and developments in social structures.

This study highlights the overall significance of the microlith finds from Gre Filla and discusses their contributions to our comprehension of the Early Neolithic's social, economic, and cultural dimensions. The discussion will involve a comparison with microliths found in other Early Neolithic sites in and around Gre Filla. Ultimately, through an examination of the transformation of microlith tools, the aim is to provide a thorough understanding of the lifestyle and techno-typological diversity of chipped stone tools during the Early Neolithic in Upper Mesopotamia and, more broadly, the Near East.

17 MINING STONE TOOLS FROM GARGANO FLINT MINES (SOUTH-EASTERN ITALY): TECHNO-TYOLOGICAL STUDY AND RAW MATERIAL CHARACTERIZATION.

Terziani, Andrea (University of Pisa - Department of Philology, Literature and Linguistics) - Volante, Nicoletta (University of Siena - Department of History and Cultural Heritage) - Cantisani, Emma (National Research Council of Italy (CNR) - Institute of Heritage Science (ISPC)) - Iannaccone, Roberta (National Research Council of Italy (CNR) - Institute of Heritage Science (ISPC)) - Magrini, Donata (National Research Council of Italy (CNR) - Institute of Heritage Science (ISPC)) - Galiberti, Attilio (University of Siena - Department of History and Cultural Heritage)

The first mining activities in our country date back to the beginning of the 6th millennium BCE. These works are represented by a set of structures involved in the extraction of flint nodules on the Gargano Promontory (South-eastern Italy), ranging from the Early Neolithic until the Early Bronze Age.

This contribution aims to show the results of a multidisciplinary study about some mining stone tools from five sites: Defensola A, San Marco, Martinetti, Tagliacantoni and Cruci. The study suggests a particular know-how related to the art of mining, since the first neolithization of Italy. This is demonstrated not only by the considerable extension of the underground works but also by a mining toolkit with a high degree of technological investment.

These artifacts were shaped through an expedient knapping sequence, sometimes followed by bush hammering, abrasion and polishing actions. Furthermore, notches or grooves are not so infrequent and they were put in place to fix a handle in perishable materials.

The mining tools were made exploiting local siliceous rocks with a coarse texture and sometimes even the embedding rock itself. The characterization of the raw material used in their manufacturing was obtained following an analytical protocol, using both non-invasive and micro-invasive techniques.

The samples were observed and described at different magnifications using an optical microscope. The chromatic coordinates were acquired with a non-invasive spectrophotometer. Elemental analyses were performed with a portable XRF, while the mineralogical composition was determined using X-ray diffraction on a few mg of powders. Finally, the acquired data were compared with the results of previous studies on these mines.

The collection of all these data on mining tools will enrich the knowledge about the work strategies for the exploitation of flint in the Gargano area, during the pre-protolithy.

18 COMPARABILITY OF LITHIC TECHNOLOGIES RESULTS: INSIGHTS FROM FOUR EARLY UPPER PALAEO-LITHIC ASSEMBLAGES

Gennai, Jacopo (University of Pisa, Department of Civilisations and Forms of Knowledge, Via dei Mille 19, 56126, Pisa, Italy) - Falcucci, Armando (University of Tübingen, Department of Geosciences, Early Prehistory and Quaternary Ecology working group, Schloss Hohentübingen, Tübingen, Germany) - Niochet, Vincent (Leiden University, Faculty of Archaeology, Van Steenis Building, Einsteinweg 2, 2333 CC Leiden, The Netherlands) - Peresani, Marco (University of Ferrara, Dipartimento di Studi Umanistici, Sezione di Scienze Preistoriche e Antropologiche, Corso Ercole I d'Este, Ferrara, Italy) - Richter, Jürgen (University of Cologne, Faculty of Humanities, Institute of Prehistoric Archaeology, Weyertal 125D - 50931 Köln, Germany) - Soressi, Marie (Leiden University, Faculty of Archaeology, Van Steenis Building, Einsteinweg 2, 2333 CC Leiden, The Netherlands)

Lithic studies play a pivotal role in Prehistoric Archaeology. Lithic assemblages have been used as proxies of human groups and often grouped into technocomplexes trying to present ethnic similarity. These might not mirror reality, especially during the Early Upper Palaeolithic (EUP) when a quick dispersal of Homo sapiens groups occurred, and related bio-cultural dynamics are still under investigation. Therefore, it is important to create a reference framework for lithics avoiding preconceived labels as much as possible. In addressing these issues, we run a comparative analysis between four Early Upper Palaeolithic (EUP) assemblages using a large, open-access database. These assemblages belong to stratified, taphonomically consistent, and radiometrically dated contexts to the 41-38 ka cal BP interval. Furthermore, they span the geographic extent of the EUP dispersal range, from the Near East to Western Europe. Following FAIR data principles, the raw data are stored in a public long-term repository, and our analyses are conducted transparently and reproducibly using the R programming language. The database includes discrete and metric attributes documenting technological processes within each assemblage. We explore the attributes and their significance through Multivariate Correspondence Analysis (MCA) which enables an effective exploration of the reduction processes and cultural adaptations during this period. Open-access databases address challenges related to data comparability and inter-analyst methodological disparities, contributing to the development of standardised protocols in lithic research. The findings provide specific insights into tool production and socio-economic organisation during the EUP, offering a factual and focused perspective on technological behaviours in prehistoric periods.

19 NEW PERSPECTIVES TO THE STUDY OF CHERT CATCHMENT AREAS FROM PYRENEAN LGM HUMAN OCCUPATIONS: THE CASE OF MONTLLÉO (SPAIN)

Sanchez de la Torre, Marta (Seminari d'Estudis i Recerques Prehistòriques (SERP), Universitat de Barcelona; Institut d'Arqueologia de la Universitat de Barcelona (IAUB)) - Rafart, Eulàlia (Seminari d'Estudis i Recerques Prehistòriques (SERP), Universitat de Barcelona; Institut d'Arqueologia de la Universitat de Barcelona (IAUB)) - Mangado, Xavier (Seminari d'Estudis i Recerques Prehistòriques (SERP), Universitat de Barcelona; Institut d'Arqueologia de la Universitat de Barcelona (IAUB)) - González Olivares, Cynthia (Seminari d'Estudis i Recerques Prehistòriques (SERP), Universitat de Barcelona; Institut d'Arqueologia de la Universitat de Barcelona (IAUB)) - Gratuze, Bernard (Institut de Recherche sur les Archéomatériaux - Centre Ernest Babelon (IRAMAT-CEB), CNRS - Univ. d'Orléans) - Rubio Campillo, Xavier (Grup de recerca Didàctica i Patrimoni (DIDPATRI), Universitat de Barcelona; Institut d'Arqueologia de la Universitat de Barcelona (IAUB))

The archaeological work developed at the site of Montlleó for more than twenty years has allowed documenting a long sequence of human occupation that begins during the LGM, around 23,000 cal BP and ends after the LGM, around 17,000 cal BP. To the obtained radiocarbon dates and the typological variability of the lithic industry, we can now add recent studies on micro-spatial distribution that have allowed documenting at least three horizons of human occupation linked to three chronocultural periods: the Upper Solutrean, the Badegoulian and the Lower Magdalenian.

The lithic industry, abundant in the archaeological record, is composed of a polyolithological tool, with a clear predominance on the use of chert. The archaeopetrological analysis of chert tools, including non-destructive geochemical analyses, has evidenced the existence of a wide variety of exploited types, whose origin is located on both sides of the Pyrenean mountain range. Evidence of possible contacts with other groups has been attested regarding the origin of some specific tools. Furthermore, the application of novel computational approaches has allowed the team to explore the role played by the site within the network of regional spatial connectivity pathways of this mountainous area.

In this communication we would like to present the case of Montlleó as an example of the use of multifaceted methodologies of stone research with the aim of improving our knowledge about past human mobility in mountain environments.

20 CHERT SOURCING USING LIBS: APPLICATIONS TO THE CASE OF COVA DEL PARCO (ALÒS DE BALAGUER, LA NOGUERA, SPAIN)

Le Guirriec - Cornu, Julien (Universitat de Barcelona) - Sánchez de la Torre, Marta (Universitat de Barcelona) - Bousquet, Bruno (Institut de Chimie de la Matière Condensée de Bordeaux (UMR 5026), Univ. Bordeaux - CNRS - Bordeaux INP) - Lefrais, Yannick (Archéosciences Bordeaux (UMR 6034), Univ. Bordeaux Montaigne - CNRS - Univ. Bordeaux - EPHE-PSL) - Mangado, Xavier (Universitat de Barcelona) - Belén González, Cynthia (Universitat de Barcelona) - Le Bourdonnec, François Xavier (Archéosciences Bordeaux (UMR 6034), Univ. Bordeaux Montaigne - CNRS - Univ. Bordeaux - EPHE-PSL)

Lithic materials are the most commonly found artefacts on Palaeolithic archaeological sites and Cova del Parco (Alòs de Balaguer, La Noguera, Spain) is not an exception. There, cherts originating from carbonate lacustrine environments were widely exploited by Upper Palaeolithic hunter gatherers populations, and in a similar way, this type of chert was also predominant in the archaeological set of different sites chronologically related to Cova del Parco from the south of the Pyrenees. Archaeo-petrographic sourcing studies have identified different potential sources placed in the first Pre-Pyrenean foothills and the middle Ebro Basin, but these approaches were unable to distinguish between sources.

With the aim of analyzing large archaeological corpus, including museum collections, we conducted a pilot experimentation of the use Laser Induced Breakdown Spectroscopy (LIBS) for chert geochemical sourcing. This portable instrument allows fast, scalable, micro-destructive analysis, and has rarely been used for chert sourcing, with only a few exploratory applications.

In this communication we will present the use of LIBS for chert sourcing, as well as an application using supervised classification models on LIBS spectra for determining the provenance of lacustrine cherts, allowing successful discrimination of lacustrine geological sources and providing predictions for the origin of a selection of chert artifacts recovered at the Middle Magdalenian level from Cova del Parco.

21 FROM LITHIC TO LANDSCAPE: MULTIDISCIPLINARY APPROACH TO LITHIC ANALYSIS OF FIELD SURVEY EVIDENCE IN MAREMMA REGIONAL PARK (CENTRAL ITALY)

Mustone, Gaia (Siena University) - Pizzolo, Giovanna (Siena University) - Tykot, Robert (University of South Florida)

This contribution presents the results on the analysis of the lithic materials found during the archaeological field survey activities carried out in recent years by the Prehistory Unit of the Department of Historical Sciences and Cultural

Heritage in the territory of the Maremma Regional Park (Grosseto District-central Italy). The investigations are part of the broader research project “Prehistoric landscapes in the Maremma Regional Park: field survey and GIS analysis of prehistoric evidence” (PRM 2020-2025).

The study of the lithic artefacts was conducted from a multidisciplinary perspective in which techno-typological analysis, observations of traces of use were combined, as well as analysis of the origin of the raw material through the pXRF technique for the obsidian finds.

The results of the study are particularly stimulating because they testify to a long frequentation of these areas not only in the recent phases of prehistory but also in more ancient moments dating back to the Middle Palaeolithic, related to the same landscape units. In addition to this, a network of contacts both on a local and broader scale is highlighted, indicating a certain degree of dynamism of these Neolithic communities and of the Metal Age.

Among the objectives of the research, we intend to experiment comparative analyses of lithic artefacts on a topographical and landscape scale to develop the interpretation of settlement strategies in a diachronic key: from the Middle Palaeolithic to recent Prehistory.

The interaction between the analyses of lithic tools and the transformation dynamics of the prehistoric landscape offers new insights into the research of the socio-economic organization of past human groups.

22 LITHIC TECHNICAL SYSTEMS OF EARLY LATE GLACIAL HUNTER-GATHERERS IN THE SOUTHERN ALPS: INSIGHTS FROM RIPARO TAGLIENTE (ITALY)

Fontana, Federica (Università di Ferrara) - Fasser, Nicolò (Università di Ferrara) - Bertola, Stefano (Università di Ferrara; Università di Firenze) - Visentin, Davide (Università di Ferrara) - Cecchetti, Marzio (Università di Ferrara) - Zen, Chiara (Università di Ferrara)

The reconstruction of the cultural traditions of hunter-gatherer groups represents one of the major challenges of prehistoric studies since the very beginning of the history of this discipline. Beyond the many critiques that may be advanced to the traditional classification system of prehistoric cultures, lithic technical systems are still one of the key elements reflecting the way past populations adapted to different territories and interacted with one another.

The latest part of the Palaeolithic in Europe is a period of rapid cultural changes and high landscape variability connected to climatic and environmental fluctuations. In the Italian peninsula, Late Palaeolithic groups are referred to the Epigravettian. Although the characterisation of lithic technical systems of this techno-complex has been the object of several studies in the last 50 years, its variability across time and space is still far from being defined.

Riparo Tagliente is a major Late Palaeolithic site in Southern Europe with the earliest evidence of human re-occupation of the southern slope of the Alps after the LGM, starting at 17,000-16,500 cal BP. Furthermore, it is one of the few known sites in Northern Italy for this timespan. Techno-economic and functional analyses have been carried out on the lithic assemblage from the lowest occupation layers of this site, allowing us to overcome the results of previous studies. On one side, more flexible reduction sequences have been highlighted. On the other, the large-scale use of the local resources of the Lessini haut-plateau, one of the districts with the richest chert outcrops of Southern Europe, is associated with some extra-regional cherts, reflecting the persistence of the long-distance connections of the Epigravettian groups who first re-established in the Alpine area after the Last Glacial Maximum.

23 REANALYSIS OF KRAKÓW-SOWINIEC I & II - UPPER TO MIDDLE PALAEOOLITHIC TRANSITION SITES

Stremski, Igor (Institute of Archaeology Jagiellonian University)

The talk aims to present my interpretation of lithic material found at the sites of Kraków- Sowiniec I & II. These sites were explored during salvage excavations preceding the raising of the memorial mound in the late 1930s. They are included in a larger cluster of sites at Blessed Bronisława Hill (Kraków-Zwierzyniec 1, Kraków-Księcia Józefa street, Kraków-Spadzista street). Some of the lithic material has been assigned to layers; nevertheless, most of it lacks stratigraphy altogether. Technological analysis revealed that some layers contain Levallois material, which is distinctive for this particular site, while others contain volumetric concept materials. The written record of the original research is sparse. My goal is to perform in-depth technological and typological analysis to review the finds and propose a new interpretation of the site's stratigraphy. The unstratified material includes numerous Levallois cores, as well as Upper Palaeolithic materials. Further research aims to divide finds into what seems to be two major groups: Middle Palaeolithic and Early Upper Palaeolithic (most probably Aurignacian). As the collection of artefacts is incomplete due to excavation methodology, it is impossible to utilise dynamic lithic analysis. Instead, the finds are being analysed with the 'chaîne opératoire' method aiming to reconstruct the main technological threads. The analysis includes measurements, determining flint type, pinpointing any anthropological modifications to the artefact, and so on. That is followed by assigning the finds to groups of shared technological features, mostly Levallois and Aurignacian. I believe interpreting the sites with today's knowledge could be beneficial to the state of research.

1114 NON-INVASIVE ARCHAEOLOGY: INTEGRATING SATELLITE, UAV, AND GEOPHYSICS WITH TRADITIONAL FIELD METHODOLOGIES PART 2

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Wroniecki, Piotr (Montefortino Prospection & Digitalisation) - Peters, Manuel J.H. (Max Planck Institute of Geoanthropology) - Trapero Fernández, Pedro (Cádiz University)

Session format: Regular session

The archaeological workflow is being revolutionised by non-invasive methods such as geophysics and remote sensing. Their application is increasingly prevalent due to their lower cost and increased ease of use. Examples include satellites and unpiloted aerial vehicles (UAVs) with RGB, laser, and spectral sensors; geophysical techniques such as magnetometry, GPR, and resistivity; and Artificial Intelligence (AI) for data collection and interpretation.

Compared to traditional approaches, these methods are a fast way of acquiring large datasets. Their systematic integration needs further exploration however, in order to unlock the true potential of these methods when seamlessly embedded into the archaeological process. This integration ranges from large-scale approaches to study sites and landscapes, to more focused applications in excavation data analysis.

Challenges can arise due to the interdisciplinary nature of these approaches, where external specialists may not fully grasp the archaeological needs, and archaeologists may not entirely understand the possibilities and limitations of the techniques. Furthermore, data processing remains complex; a technical understanding of the method itself is often required, and the standard process does not always align with the requirements of an archaeological context. This makes data visualisation challenging, especially for techniques such as GPR and LiDAR.

This session explores the dynamic relationship between non-invasive technologies and traditional methods in research-driven and development-led archaeology. We invite contributions dealing with the integration, comparison, and validation of non-invasive and invasive methods, including the use of remote sensing, geophysical prospection, pedestrian survey, coring, and excavation. Digital aspects of the workflow, including GIS, spatial analysis, and Artificial Intelligence, are also welcomed. Reflections concerning the theoretical and technical application of non-invasive methods are invited, as well as insights and considerations regarding methodology, potentially aligning with broader efforts to standardise methodologies and datasets across projects and regions. We encourage the evaluation of both successful and unsuccessful outcomes.

ABSTRACTS

1 STALAG VIII B (344) LAMSDORF IN THE LIGHT OF INTEGRATED ARCHAEOLOGICAL RESEARCH. THE CASE OF 60 ITALIAN POWS FROM LAMSDORF

Pawleta, Michal (Adam Mickiewicz University) - Kobińska, Dawid (University of Łódź)

The Site of National Remembrance in Łambinowice, Poland is an area of former prisoner of war and resettlement camps that operated near the village at various times. Only in the years 1939-1945, as can be generally estimated, 300,000 soldiers of the anti-Nazi coalition passed through the Lamsdorf camps. Several thousand of them did not survive the time of captivity. In 2022, the Central Museum of Prisoners of War begun the implementation of an interdisciplinary project “Science for society, society for science at the Site of National Remembrance in Łambinowice”. Its main idea was to use non-invasive and invasive archaeological research methods to map and inventory the material remains of the camps that have survived in the local, mostly forested, landscape to the present day. One of the goals was an attempt to find unknown and unmarked burials of prisoners who died during captivity in Lamsdorf.

In our paper, we present the implemented project methodology, which allowed us to locate an unknown and unmarked graves. Remote sensing data were the basic and main category of sources that were acquired and analysed. These included historical maps and plans, German, English and Polish aerial photos from various years, LiDAR data and testimonies of the prisoners captivated in Lamsdorf. None of these sources provided obvious answers about the location of unknown PoW burials. However, their processing and integration in QGIS software allowed the selection of locations for GPR research. The interpretation of all the data obtained was the basis for choosing a location for test trenches. The excavations carried out confirmed that this is the final resting place of Italian soldiers interned in Lamsdorf at the end of the Second World War. The found dog tags allowed for the identification of the deceased soldiers by name. They were Giovanni Paravidino and Luigi Norcia.

2 MINERAL AND METALLURGICAL LANDSCAPE OF MOUNT AMIATA (TUSCANY, ITALY)

Dalle Vedove, Letizia (University of Siena) - Dallai, Luisa (University of Siena)

The volcanic origin of the territory of Mount Amiata (Tuscany, Italy) has contributed to generate a landscape characterized by a wide variety of mineral resources, mercury in particular, which has determined an extractive activity extended in a long durée and culminated in the most recent, intensive extraction between 19th and 20th centuries. The careful identification of well-defined areas of long-term exploitation provided the basis for investigating and reconstructing the mining and metallurgical landscape of Mount Amiata, without chronological limits, ranging from the Neolithic period until present day, and through a multidisciplinary approach. This has made it possible to delineate the mining and metallurgical landscape in different historical phases, localizing the main mining areas and metallurgical workshops. Moreover, through the support of archaeological field surveys, iconographic, cartographic (like land registries) and photographic sources (mainly historical aerial photographs taken by the Military Geographical Institute in 1954), it has been possible to measure the impact of the most recent mining activities on the landscape. The reconstruction of some mine plans has also allowed to follow the recent industrial development through an accurate reconstruction of the underground works and to localize with precision the most ancient archaeological finds retrieved during the reopening of the tunnels in 19th and 20th centuries.

3 FROM NON-INVASIVE SURVEY METHODS TO EXCAVATION: EXPLORING IRON AGE HILLFORTS AND ROMAN SETTLEMENTS IN THE ALISTE RIVER VALLEY, ZAMORA, SPAIN

Soler Rocha, Rafael (AOC Archaeology; Universidad de Granada; Zamora Protohistórica) - Rodríguez Monterrubio, Óscar (Zamora Protohistórica) - González de la Fuente, Francisco (Zamora Protohistórica) - Eguilleor Carmona, Xabier (Zamora Protohistórica; Universidad de Salamanca) - Álvarez Cano, Óscar (Zamora Protohistórica)

The Aliste River Valley (Zamora, Spain) presents a high concentration of archaeological sites, especially hillforts, often defined as “Castros” and attributed to the Iron Age without having been extensively studied. In fact, this area has remained largely unnoticed by archaeological research, and systematic studies have scarcely been carried out since the 1970s.

Since 2018, the Research Group Zamora Protohistórica has been conducting a Landscape Archaeology Project, which initially consisted of two major LiDAR Programmes. The first of these focused on characterising the Castro de La Encarnación – 7.3 hectares – (Rabanales, Zamora, Spain), defining the outer ditched and walled enclosures, as well as the internal structures. This programme was also complemented by a GPR geophysics survey on two areas potentially containing internal structures. Finally, the site was excavated between 2018-2020 through the execution of several small and medium-sized open areas. The results have revealed the existence of a massive settlement from the second Iron Age to Roman times.

The second LiDAR programme focused on the municipality of Rabanales and was complemented by the photogrammetric survey of the hillforts Castro de La Encarnación, San Juan, Gallinera, Fradellos, and El Castrico. The uniqueness of the latter led to an archaeological walkover survey in 2019, which along with a third LiDAR programme, defined a series of areas that were further surveyed using GPR. The results showed the existence of a series of linear structures, in line with some patterns of Roman urbanism, and in correlation with the results obtained in the walkover survey. Since 2021, three excavation seasons have been carried out at El Castrico, revealing the existence of a Roman settlement, previously unknown at a spatial level.

The preliminary results of both excavations provide us with sufficient knowledge to discuss the benefits and limitations of the application of non-invasive methods in Archaeology.

4 NEW EXCAVATIONS AT CRESWELL CRAGS: A LANDSCAPE APPROACH USING GPR

Perez Arana, Andres (University of Sheffield) - Kuykendall, Kevin (University of Sheffield) - Cockrell, Timothy (University of Sheffield) - Jones, Angharad (Creswell Crags)

Creswell Crags is a gorge located in the Magnesian limestone on the Derbyshire/ Nottinghamshire border with a long history of archaeological and palaeontological excavation (late 19th - early 21st century). These excavations have produced a wealth of archaeological and osteological material that is important for our current understanding of hominin presence, absence, and adaptation during the Middle to Late Upper Palaeolithic in Britain. However, different field methodologies and excavation strategies used over the years and the distribution and loss of important artefact collections have been problematic.

We began new excavations at Creswell Crags in 2019, aiming to recover Middle and Upper Palaeolithic archaeology from non-cave localities in the Creswell gorge and the surrounding landscape. We have recovered artefacts representative of the Middle Palaeolithic to historic periods, but most of these are derived from highly disturbed and mixed contexts inhibiting use for archaeological interpretation. Over the past two seasons, our field strategy includes the use of ground penetrating radar (GPR) and UAV-SfM survey (Unmanned Aerial Vehicles - Structure from Motion)

to locate productive contexts for test pit excavations in the Creswell gorge and surrounding landscape. During July 2023, we undertook a geophysical survey over two areas (0.21 - 0.33 ha) in the landscape surrounding Creswell Crags. The aim was to identify geological features in the buried bedrock limestone with the potential to preserve intact pre-glacial deposits with the potential to recover archaeological materials, and to identify specific areas for future excavation.

Our excavations at Creswell Crags demonstrate that new Middle and Upper Palaeolithic archaeological materials can be recovered from non-cave contexts in the Creswell Crags landscape, and the use of GPR has strong potential to identify additional productive contexts for future excavation, both at Creswell Crags and at other geologically similar regions where a similar field approach can be applied.

5 INVESTIGATING THE BIOGRAPHY, LAYOUT AND FUNCTION OF A NEOLITHIC ENCLOSURE. CASE STUDY FROM DZIELNICA (SW POLAND)

Furmanek, Miroslaw (University of Wroclaw, Institute of Archaeology)

The aim of the presentation is to discuss the comprehensive archaeological study of a Neolithic enclosure at Dzielnica, south-west Poland. This research integrates non-invasive archaeological methods, including geochemical (phosphate analysis) and magnetic gradiometry prospection, aerial photography and excavation. The primary aim of the project was to reconstruct the biography, layout and functional aspects of past activity in the prehistoric landscape. The results from Dzielnica have revealed a complex, multi-phase palimpsest of different traces of practices of Neolithic and Bronze Age societies, tracing complex phenomena of continuation and transformation of socio-economic and ritual functions over time. The geochemical signatures and magnetic anomalies have outlined the extent of the enclosure and provided insights into the structural composition and activities that took place on the site. This includes evidence for settlement areas, potential ritual and funerary spaces, highlighting the site's role as a focal point in a regional and inter-regional network.

The integration of excavation, environmental and non-invasive data has allowed for a nuanced understanding of the interaction between Neolithic and Bronze Age communities and their landscape. This has allowed a key to the interpretation of non-invasive datasets to be built, outlining their possibilities and limitations in the documentation and revealing of past activities.

The Dzielnica case study exemplifies how interdisciplinary methods can reveal the complex narratives of prehistoric enclosures and contribute to our knowledge of the spatial organisation, social structures, and cultural practices of the Neolithic and Bronze Age societies.

The work is supported by the programme entitled “Excellence Initiative – Research University” (IDUB) for the years 2020-2026 for the University of Wroclaw, internal grant no BPIDUB.28.2024.

6 THE UNUSED POSSIBILITIES OF NON-INVASIVE PEDESTRIAN SURVEYS IN THE NETHERLANDS. A VERIFIED BUT UNUSED METHOD WITHIN THE DUTCH QUALITY STANDARD

de Raad, Jesper (Leiden University)

The archaeological sector in the Netherlands works with legislation for all institutions. More specifically, an institution needs to be certified to be able to execute scientific archaeological research. Every invasive archaeological intervention, including archaeological coring, needs to be executed by such a certified institution.

Non-invasive pedestrian surveys are embedded in the quality standard of Dutch archaeology (KNA), but they are not always useful in commercial archaeology. The reasons for this are: (1) the method depends on various natural phenomena, which are not always present; (2) the commercial labour prices are too high; (3) the season of the archaeological research is not ideal for the specific field survey. However, executing an archaeological pedestrian survey, or rather a full systematic archaeological regional description (Landesaufnahme), is a useful method. Specifically, around archaeological monuments, in extensive areas, or near areas with high archaeological expectations.

Additionally, the method of non-invasive pedestrian survey is very useful as a citizen science project. Archaeological volunteers can execute the necessary pedestrian surveys, accompanied by an archaeologist, and finalise a scientific archaeological research project without any forbidden invasive damage to the soil. The volunteer is incorporated into the scientific system and the local/regional archaeologist gains more information of the in-situ archaeology and landscape.

7 ARCFIELDLAB – STIMULATING NETWORKS, KNOWLEDGE EXCHANGE, AND EXPERIMENTATION IN APPLIED SENSOR ARCHAEOLOGY FOR DUTCH FIELD RESEARCH

Scholte, Mason (4D Research Lab, Universiteit van Amsterdam) - Waagen, Jitte (Amsterdam Centre for Ancient Studies and Archaeology / 4D Research Lab, Universiteit van Amsterdam)

In Dutch archaeological fieldwork there are increasingly innovative applications of new technology, ranging from drones with various sensors, new geophysical instruments, automated auguring tools and so on and so forth. Funded by the European E-RIHS initiative, the 4D Research Lab leads the ARCFIELDLAB project consortium in The Netherlands to provide archaeological professionals with insights into the possibilities and limitations of these novel techniques.

The aims of ARCFIELDLAB are to stimulate networks of archaeologists and specialists, facilitate knowledge exchange and promote experimentation with cutting-edge technology, all in the field of sensor archaeology for terrestrial and maritime contexts. These are addressed by organizing expert meetings, creating a central website to share community-generated knowledge on the applicability of the various techniques, funding case studies, and creating and sharing best practices. One of the additional aims that has been formulated in the course of the first expert meeting is to establish so-called 'benchmark sites' – a series of sites on different soils and with different types of archaeological contexts that should be researched using different sensors in a comparative and integrative multitemporal approach.

This presentation aims to share the progress so far, discuss the potential of benchmark sites, and explore the possibility to do this in an international context.

8 IDENTIFICATION OF ARCHAEOLOGICAL ELEMENTS WITH GROUND-PENETRATING RADAR (GPR): LABORATORY PRACTICES AND COMPARISON WITH REALITY

Oliveira, Rui (Instituto de Ciências da Terra, Universidade de Évora, Évora, Portugal; Departamento de Física, Universidade de Évora, Évora, Portugal; Earslab - Earth Remote Sensing Laboratory, Universidade de Évora, Évora, Portugal) - Traperó, Pedro (Área de Historia Antigua, Departamento de Historia, Geografía y Filosofía, Universidad de Cádiz, Spain; Earth Remote Sensing Laboratory (EaRSLab), Universidade de Évora, Portugal; Centro de História da Arte e Investigação Artística (CHAIA), Universidade de Évora, Portugal) - Caldeira, Bento (Instituto de Ciências da Terra, Universidade de Évora, Évora, Portugal; Departamento de Física, Universidade de Évora, Évora, Portugal; Earslab - Earth Remote Sensing Laboratory, Universidade de Évora, Évora, Portugal)

The application of non-invasive and non-destructive techniques in geophysical prospection, has become a common practice in the search for archaeological elements without resorting to excavation. The interaction between archaeologists and geophysicists has not always been ideal, with archaeologists possessing the tools to process and understand the data, while geophysicists face their own set of challenges. The complexity of the process increases further when seeking a historical interpretation, such as the reconstruction of a site's layout or the interpretation of its elements. Recognizing the need for improved collaboration, we present a series of experimental case studies wherein various scenarios that may arise in an archaeological context are reproduced using idealized laboratory conditions. The study involves a comparative analysis between archaeological remains on a small scale, buried within a uniform medium composed by coarse sand, and data obtained by ground-penetrating radar (GPR) using a 1600 MHz antenna. The obtained results are then compared with the geometry of the buried objects, and a discussion ensues regarding the feasibility of addressing typical historical and archaeological questions based on this analysis.

Acknowledgment: The work was supported by the Portuguese Foundation for Science and Technology (FCT) project UIDB/04683/2020 - ICT (Institute of Earth Sciences).

9 THE GOOD, THE BAD AND THE UGLY- DUTCH DESK-BASED ARCHAEOLOGICAL RESEARCH AN EXAMPLE OF MULTIDISCIPLINARY APPROACH. CHANCE OR WASTED RESOURCE?

Durczak, Kinga (Antea Group)

In Dutch commercial archaeology, desk-based research initiates a multi-step process to assess archaeological potential, including survey drilling, trial trenching, and definitive excavation. In most cases, the desk-based research leads directly to or is combined with survey drilling. Researchers investigate various aspects such as geology, geomorphology, LIDAR, aerial images and additional data like paleogeography and groundwater levels in GIS environment. Integrating archaeological and historical information theoretically aids in identifying potential of the site.

However, discrepancies between intended outcomes and data quality persist. The requirements for the use of data (lidar, aerial photos, geological, legacy data etc. usually an open-source) do not always leads to the correct conclusions and understanding of the potential of the landscape. The Dutch archaeological expectation model primarily employs an inductive approach, with occasional instances of a deductive system, resulting in data incompleteness and inconsistencies. Furthermore, challenges arise from the diverse landscapes and their archaeological potential, while varying models across municipalities exacerbate gaps and weak links between data, modelling, and assessment outcomes.

Archaeological prospection ideally serves as a robust cornerstone for subsequent research endeavours. However, its efficacy significantly depends on the proficiency of researchers, the experience of reviewers, and the accessibility of relevant data. Unfortunately, there is often a lack of comprehensive resources explaining the models used to assess archaeological potential and establish connections with geomorphological data. Moreover, there is currently no push from the archaeological companies, municipalities, and government to create an appropriate resource. This shortage of explanatory materials poses challenges and impedes the seamless integration of diverse datasets crucial for informed decision-making in archaeological investigations.

Despite the potential of desk-based research, it is frequently underutilized. Addressing systemic errors and theoretical gaps requires collective effort, yet responsibility allocation remains unclear. These challenges must be tackled to maximize archaeological data usage and prevent resource waste.

10 COMPARATIVE NON-DESTRUCTIVE SURVEYS ON CENTURIATED ROMAN LANDSCAPE

Bödöcs, András (Eötvös Loránd Tudományegyetem) - Márkus, Gábor (Archaeodata 1998 Ltd.)

To understand the former territory and Roman land use of Savaria, the first Roman colony of Pannonia, a research programme was launched in 2022. The main objective was to identify the land allotted to the veterans settled on the land of the former colonia, to map the land use traces and the relationship between the veteran estates. Traces of land distribution previously we reconstructed using a GIS predictive model and then identified from aerial photographs. Although we have been able previously to identify concrete traces of this, we still do not know exactly the main aspects of the land allocation. We would like to understand and identify features that can be compared with the texts of ancient sources. For example, how many veterans shared a centuria, a Roman centuria unit (ca. 710×710m).

Therefore, we aimed at surveying large areas with non-destructive methods. So we arrived to the other main objective of our project: to investigate the potential of using multispectral drones in archaeological research, especially in landscape archaeology. We therefore started to survey the elements of the Roman centuriatio allocation. For this work we acquired a DJI P4 MultiSpectral drone, with which we started monitoring several pre-selected areas. These areas were assumed to be complete Roman centuria units (>50ha). We tried to compare the data obtained from these flights with the results of 16 channel fulxgate magnetometer surveys of the same areas. In our presentation we would like to illustrate with examples the pitfalls, possibilities, positive and negative aspects of the surveys and the comparison of the results.

11 COMPARISON OF LARGE-SCALE MAGNETOMETRY MEASUREMENTS WITH EXCAVATION DATASETS IN EASTERN HUNGARY. FEATURE DETECTABILITY AND IDENTIFICATION POSSIBILITIES

Mesterházy, Gábor (Hungarian National Museum - National Institute of Archaeology) - Pethe, Mihály (Hungarian National Museum - National Institute of Archaeology)

In 2009, David Jordan highlighted the half-century track record of archaeological geophysics' effectiveness. Since then, the adoption of non-invasive geophysical methods in scientific and development-led archaeological research in Europe has gradually increased. Despite the widespread use of geophysical measurements for various archaeological objectives. Many studies often focus solely on processing and interpreting data without adequately addressing feature detection probabilities, identifiable feature types, and undetectable archaeological features.

This study examines two sections of motorway in Jász-Nagykun-Szolnok county, Eastern Hungary: the 19 km M4 section between Abony and Fegyvernek, and the 33 km M44 section between Tiszaug and Szarvas. Geophysical surveys, conducted in 2013 and 2014 across 67 hectares using magnetometry, were complemented by trial trenching and full-scale excavations in subsequent years, yielding a significant dataset for comparison. The presentation aims to analyze the physical and cultural properties of archaeological phenomena by comparing features from magnetometry, survey interpretation, and excavation. Each method has its limitations and biases: magnetometer surveys are influenced by measurement settings and soil properties; survey interpretation depends on the expertise of the interpreter; and the success of excavations is impacted by the archaeologists' skills.

Our approach not only offers an overview of detection rates but also delves into the analysis of detection and misinterpretation rates by feature type, chronological categories, and properties (size, depth, topsoil depth). Through this comprehensive examination of large-scale datasets, we have enhanced our understanding of regional feature detection capabilities.

1119 CRAFTS IN THE ROMAN WORLD: PRODUCTION, DISTRIBUTION, AND PEDAGOGY

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Stemberger Flegar, Kaja (PJP d.o.o.) - Lundock, Jason (Full Sail University)

Session format: Regular session

Whether for private use within the household or to create surplus product for trade, the production of crafts would have been a pervasive part of life for many of the inhabitants of the pre-modern world. With a mix of household production, small scale communal workshops, as well as industrial scale factories and warehouses, the Roman world provides a rich and diverse environment to examine crafting in its many forms. This panel seeks to examine all stages of craft production, ranging from the dissemination of the skill sets required and the process of procuring materials to the ways in which craftspeople laboured to produce their goods and how these products were distributed. There will also be interest in the place of craftspeople within wider society, their status and identities, both from the perspective of household production as well as industrial scale operations. This panel seeks to develop a conversation on how the lived experience of craft production shaped the lives and wider society of those involved and offer new perspective into life during the Roman period.

ABSTRACTS

1 UNRAVELING TESSERAEE ARRANGEMENT TECHNIQUES IN LARGE-AREA PLAIN MOSAICS OF HERCULANEUM

Lim, YongBing (Faculty of Human-Environment Studies, Kyushu University, Japan) - Hori, Yoshiki (Faculty of Human-Environment Studies, Kyushu University, Japan)

Mosaics involve the arrangement of tesserae to create a uniform surface, and proper alignment is essential, especially in the plain sections of mosaics. In Pompeii, some early mosaics arranged tesserae randomly but later mostly in rows with varying directions. Figurative mosaics followed composition; plain mosaics arranged tesserae rows obliquely or parallel to the border.

As the discussion focuses primarily on figurative mosaics, the existence of plain mosaics is often ignored. Not only are there floors of all-white plain mosaics, but large-area plain mosaics may also be used in the background or within the spaces of patterned mosaics, as in the background of mosaic of street musicians in Villa of Cicero and mosaic of dog in Casa di L.Cecilio Giocondo (V.1.26Pompeii). Here at Pompeii and Herculaneum, where the existing figurative mosaics were situated in the absolute center for any such development, techniques more in accordance with making-up practice would not have seemed out of place. Historically before covering entire floors, opus tessellatum plain mosaics were used in the 2nd century BC to fill large spaces around the central panel of emblemata. These early applications of opus tessellatum to entire floors in Pompeii in the 1st century BC were plain mosaics and continued until the end of that city.

This study aims to investigate the laying techniques of large-area plain mosaics of House of Mosaic atrium and Central Baths Herculaneum. We examine the chronological and spatial characteristics of the use of oblique and parallel arrangement of tesserae rows. Using laser scanning and photogrammetry, the specific rules and practices for arranging tesserae in these large-area rows are revealed. Through this research, we identify the working methods applied by craftsmen for laying large-area plain mosaics effectively and beautifully, providing insight into the nuances of craftsmanship during this period in mosaic history.

2 COARSE WARE TRANSFORMATIONS

Wenn, Camilla Cecilie (Museum of Cultural History, University of Oslo)

The paper presents a case study of pottery production from the Latin site Ficana, some 20 km southwest of Rome. The study investigates primarily coarse ware pottery from zone 6b, excavated 1978-1981. The majority of the pottery stems from what appears to be pottery dumps and dates from ca. 650 to 300 BC. An overview of various traits found within the material and how they change over time will be presented and discussed. In general, the changes relate to increased standardisation and efficiency. It will be argued that the organisation of the production transformed, and that pottery production developed from a more occasional craft with shared ideas that were executed more or less similarly, to a specialised production with notably less variation. The transformation of production modes has been documented in much of Etruria and Latium and thus places the material and the site into a larger context. The implications of the changes for the population will also be touched upon.

3 LEATHER INDUSTRY IN ROMAN PANNONIA: WHAT CAN WE TELL WITH LIMITED EVIDENCE

Lenár, Vilmos (Eötvös Loránd University)

Leather industry in the Roman Empire is a fairly well researched field, with world famous sites, abundance of leather items, evidence of workshops or even the tanning infrastructure. But what can we look for, when the environment is not kind to the organic material, where are (seemingly) none of the easily identifiable features of the leatherworking process? This paper focuses on offering alternatives in terms of the findmaterial from Pannonia, where a thorough (re)investigation is more than necessary. From skinning- and a tanning knives to a house in Aquincum, which could be the place for auxiliary processes of leatherworking. The author argues, there is evidence for various processes of the leather industry to have taken place in Pannonia, just these were overlooked by the academic conversation in the past regarding the province. With growing focus on not just leatherworking as a whole, but a series of particular and different processes we might be able to better understand the tools and their usage, while examining the sites that provide these finds could help us better understand the people, who were involved in leatherworking in a province on the border of the Empire.

4 COPPER ALLOY SPINDLE AND SPINDLE-WHORL FROM SERMIN

Jančar, Mojca (Independent researcher) - Kovacic, Ana (Independent researcher)

In this paper I address the copper alloy spindle and its corresponding spindle whorl found in 2020 on the Roman road in Sermin (coastal settlement near Koper in modern day Slovenia). This relatively large site was excavated during motorway construction works and includes a Roman road, as well as a handful of Roman period cremations and a burial plot that could be dated to the 3rd century AD.

The purpose of this paper is twofold. Firstly it presents the spindle in relation to other objects that can be connected to the Roman period manufacture of textiles in this region of Slovenia. Additionally it discusses how this object may have been used due to its uncharacteristic slimness, and if the shape influenced the quality of the thread. The second, ultimate aim is to ascertain the role and extent of fabric production for this area in the Roman times. The sites lies in relative proximity to Aquileia, one of the biggest import centres in the region.

5 RECYCLING AND REUSING POTTERY AND GLASS IN THE CONTEXT OF CRAFTS: CASE STUDY COLONIA ULPIATRAIANA POETOVIO

Stemberger Flegar, Kaja (PJP d.o.o.)

This paper addresses the recycled objects found at the pottery kiln site in Roman Colonia Ulpia Traiana Poetovio (modern day Ptuj, Slovenia). While processing the finds, certain types of reused objects stood out. Several broken pieces of glass and, to a lesser degree, pottery sherds had been re-touched into functional tools. In Roman archaeology, such objects are not frequently studied, but when found, they are usually related to pottery production and leather crafting. The analysis of tools made from glass shards was relatively straight forward when they were examined with the same methodology as prehistoric stone tools. The glass objects could be predominantly classified as scrapers, blades, and drills. More intriguing were objects made from retouched terra sigillata vessels and other pottery. Some of the bottoms had been reshaped so they could serve as lids, while others had been sanded down to form geometric shapes. In the context of the Roman kiln complex, these could be interpreted as potter's ribs.

1120 HUMAN ENVIRONMENT INTERACTIONS IN THE EURASIAN STEPPES FROM PREHISTORY TO THE EARLY HISTORICAL PERIODS

Session theme: 7. Archaeology of Sustainability through World Crises, Climate Change and War

Session organisers: Cromartie, Amy (Cornell University; Cultures et Environnements Préhistoire, Antiquité, Moyen Âge (CEPAM)) - Joannin, Sébastien (CNRS, UMR 5554 Institut des Sciences de l'Evolution de Montpellier (ISEM)) - Lhuillier, Johanna (CNRS, UMR 5133 Archéorient, Maison de l'Orient et de la Méditerranée) - Ricci, Andrea (Cluster of Excellence Roots, Christian-Albrechts-Universität zu Kiel)

Session format: Session with keynote presentation and discussion

Today's climate crisis is causing aridification and desertification across the world. In the mid-latitudes, semi-arid and arid steppe biomes are under the most severe constraints. These biomes have seen their distribution expand (already more than 40% of the earth's surface) to the detriment of forested environments. As aridification continues, populations across these regions will be required to seek adaptation strategies to sustain their agro-pastoral and food production strategies, adaptations that have the potential to disrupt the steppe ecology.

The session focuses our inquiry on the past to find solutions to the complex challenges of living in and adapting to Eurasia's changing arid and semi-arid environments. Geographically, the mid-latitudes zones of Eurasia are an expansive continental zone characterized by a semi-arid climate dominated by steppes and desert biomes. These environments

have been the backdrop of human populations across the Holocene, from nomadic to complex societies, and were home to the historic Silk Road.

For this session, we intend to gather papers that develop an interdisciplinary approach between archaeology, palaeoecology, and paleoclimatology to answer questions regarding sustainability, resilience, and adaptations between humans and their ecology across this vast geographic region. We welcome papers from archeology, paleoclimatology, paleoecology, archaeobotany, geoarchaeology, hydrology, landscape archeology, zooarchaeology, and related disciplines from local to regional scales. These papers can chronologically span prehistory to the early historical periods.

ABSTRACTS

1 HUMAN RESPONSES TO ENVIRONMENTAL CHANGE ON THE SOUTHERN COASTAL PLAIN OF THE CASPIAN SEA DURING THE MESOLITHIC AND NEOLITHIC PERIODS

Leroy, Suzanne (Aix-Marseille University) - Amini, Arash (Golestan University) - Gregg, Michael W. (University of British Columbia) - Marinova, Elena (Cultural Heritage Baden-Württemberg) - Bendrey, Robin (University of Edinburgh) - Fasel Nashli, Hasan (University of Tehran)

This paper presents results of a multidisciplinary research initiative examining human responses to environmental change at the intersection of the southern coastal plain of the Caspian Sea and the foothills of the Alborz Mountains during the terminal Pleistocene and early Holocene. Our palaeoenvironmental analysis of two sedimentary cores obtained from a lagoon in close proximity to four caves, occupied by human groups during the transition from hunting and gathering to food-producing ways of life in this region, confirms Charles McBurney's 1968 hypothesis that when Caspian Sea levels were high, Mesolithic hunters were reliant on seal and deer, but as water levels receded and a wide coastal plain emerged, hunters consumed a different range of herbivorous mammalian species.

Palynological evidence obtained from these two cores also demonstrates that the cool and dry climatic conditions often associated with the Younger Dryas stadial do not appear to have been extreme in this region. Thus, increasingly sedentary hunting and gathering groups could have drawn on plant and animal resources from multiple ecological niches without suffering significant resource stress or reduced population levels that may have been encountered in neighbouring regions. Our analyses of botanical, faunal and archaeological remains from a recently-discovered open-air Mesolithic and aceramic Neolithic site also shows an early process of Neolithization in the southern Caspian basin, which was a very gradual, low-cost adaptation to new ways of life, with neither the abandonment of hunting and gathering, nor a climatic trigger event for the emergence of a low-level, food-producing society.

2 INTERDISCIPLINARY ARCHAEO-ENVIRONMENTAL STUDIES AT KIMIREK-KUM 1, UZBEKISTAN: THE PALAEO-ECOLOGY OF A 2ND MILLENNIUM BC DELTA SYSTEM

Rouse, Lynne (Eurasia Dept, DAI) - Castellano, Lorenzo (New York University) - Hubbard, Eric (University of Pennsylvania) - Hunter, Sydney (The Ohio State University) - Jürcke, Friederike (University of Cambridge) - Müller, Daniela (University of Liverpool) - Pini, Roberta (CNR - Istituto di Geologia Ambientale e Geoingegneria) - Stark, Sören (ISAW - New York University)

The archaeological site of Kimirek-kum 1 (KK1) provides a key opportunity to investigate the interconnections of environmental change and human adaptation in proto-historic Central Asia. Dated to the second half of the 2nd millennium BC, KK1 sits at the interface of broad environmental and social changes that mark the regional Bronze to Iron Age transition. In this presentation, drawing on a variety of paleo-ecological data, we lay the groundwork for characterizing the local environment at the time of KK1's occupation. We examine this data in light of the site's location in a now-arid former delta of the lower Zerafshan River, 60 km northwest of the city of Bukhara (Uzbekistan) and well beyond the historical boundaries of the agricultural zone. Excavations at KK1 in 2022 and 2023 provided a wealth of charred plant material and wood charcoal from stratigraphic contexts; numerous sediment samples from the same contexts provide the basis for pollen and phytolith studies. Analyses of these various datasets are being carried out through early 2024, and together will provide firm insight into this deltaic palaeo-environment in the late 2nd millennium BC, and how diversified plant use by KK1's inhabitants may have mitigated (or exacerbated) subsistence risks in a possibly volatile river delta ecosystem. Alongside these plant-based analyses, advanced modeling of the ancient delta system based on Multi-Scale Relief Model (MSRM) algorithms fine-tuned for this area are enhancing our understanding of the hydrological network on which KK1's inhabitants relied. Interweaving KK1's archaeobotanical, anthracological, palynological, and geo-hydrological analyses provides a robust foundation for detailing the palaeo-ecology of the lower Zerafshan during the region-wide reconfigurations of Bronze-Iron Age transition. Our collective work is also a critical step towards building interdisciplinary approaches to investigate Central Asia's incredibly long history of human adaptation to unique and ever-changing local environments.

3 STEPPE SUSTAINABILITY IN A CHANGING WORLD

Joannin, Sebastien (CNRS - ISEM) - Palumbi, Giulio (CNRS - CEPAM) - Colombié, Claude (Université Lyon1 - LGL TPE) - Ollivier, Vincent (CNRS - LAMPEA) - Peyron, Odile (CNRS - ISEM) - Cromartie, Amy (CNRS - CEPAM) - Dugerdil, Lucas (Université de Montpellier - ISEM; ENS Lyon) - Lhuillier, Johanna (CNRS - Archéorient) - Consortium, Stepability (ANR - France)

The arid steppe ecosystems characteristic of the Arid Circum-Caspian Zone (ACC) are favoured by current and future climate change. It is therefore essential to better understand the ecosystem services that they are able to provide on a sustainable basis, in particular for human societies, particularly nomadic or semi-nomadic and pastoral.

In the ACC, socio-anthropological interpretations of burial sites or settlements show the cohabitation in the Bronze Age of nomadic pastoralism, associated to highly developed wheeled transport and interregional trade, with proto-urban societies. If these practices are determined by steppe environments, then the study of the sustainability of these poorly documented ecosystems needs to include both archaeological and paleo-ecology.

Within the Stepability project, interdisciplinary approaches are gathered to test, depending on several types of agrarian, cultural and societal developments, the vulnerability or resilience of steppe ecosystems with a view to sustainable exploitation. To do this, the interaction between researchers from different disciplinary fields (from archaeology to paleoecology / paleoclimatology) is necessary. Several study areas are targeted: Caucasus countries (Azerbaijan, Armenia) and Central Asia countries (Uzbekistan and Turkmenistan). In these workshop zones, the history of domestication, of the agro-pastoral impact and then of intensive livestock farming will make it possible to establish a scale of impact of agro-pastoral practices on the resilience of steppe ecosystems since the Bronze Age.

4 ARCHEOLOGICAL STRUCTURES AS POTENTIAL ENVIRONMENTAL ARCHIVES; FIRST NON-DESTRUCTIVE STUDY FROM SOUTHERN KYRGYZSTAN

Vatanev, Atilla (Department of Archaeology, Faculty of Arts, University of West Bohemia) - Vařeka, Pavel (Department of Archaeology, Faculty of Arts, University of West Bohemia) - Kočár, Petr (Department of Archaeology, Faculty of Arts, University of West Bohemia) - Chajbullin Košťál, Jozef (Department of Archaeology, Faculty of Arts, University of West Bohemia) - Lisá, Lenka (Institute of Geology, Academy of Sciences of the Czech Republic) - Petr, Libor (Department of Botany and Zoology, Faculty of Science, Masaryk University) - Šůvová, Zdeňka (Department of Archaeology, Faculty of Arts, University of West Bohemia) - Bajer, Aleš (Department of Geology and Soil Science, Faculty of Forestry and Wood Technology, Mendel University in Brno) - Sultanov, Emil (National Academy of Sciences of the Kyrgyz Republic, Department of Archaeology of the Institute of History, Archeology and Ethnology named after B. Džamgyrčinov) - Osmonova, Samara (Faculty of History and Social Work, Osh State University)

The environmental and geoarchaeological interpretation of settlement hill structures interpreted as tepe at locality Ak-Jar in southwestern Kyrgyzstan are the main aim of the study. The fact that these structures are located on one of the Silk road branches at the eastern edge of Fergana Basin make the study important not only from the point of climatic changes, but also from the point of understanding the settlement and subsistence strategies in that time.

Approximately 1 km long linear structure, composed of six settlement hills, located at the eastern edge of village Ak-Jar, were in the first stage of archaeological research studied only non-destructively. It generally means they were studied on the basis of surface research observations and aerial documentation. The edges of eroded tepe 2 were the subject of more detailed geoarchaeological approaches. In case of tepe 2 the sedimentology, micromorphology, geochemistry, archaeobotany, palynology, malacology, zoology, C14 and OSL dating was applied. The chronology of tepe structures was studied by C14 dating.

The C14 dates show the timespan of the tepe settlement between 250 BC to 400 AD. The well-developed calcisols (russ.: "sierozems") with significantly bioturbated horizon are buried under the tepe's structures. These soils developed under arid climate and high bioturbation reflect the movement of larvae into deeper horizons to survive the hottest part of the season. In one part of the eroded tepe were documented sediments of the water reservoir. The sedimentation inside the structure lasted not more than 150 years and represents the environmental archive from the main phase of the tepe function. The spectra of crops reflect arable agriculture, probably including the crop of grapes. Sheep pastoralism was probably the main source of the meat, but there is also evidence of turtle consumption.

5 RODENT'S AS PALAEOECOLOGICAL PROXIES TO RECONSTRUCT PAST ENVIRONMENTS OF EURASIA

Rey-Rodriguez, Ivan (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA); Universitat Rovira i Virgili) - López-García, Juan Manuel (Institut Català de Paleoeologia Humana i Evolució Social (IPHES-CERCA); Universitat Rovira i Virgili)

Eurasia, the westernmost subregion of Asia, constitutes a significant passage between Africa, Asia, and Europe. Over the last decade, there has been a notable increase in small vertebrate studies in this region, primarily due to their utility in palaeoenvironmental and palaeoclimatic reconstructions.

Considering this background, this communication aims to present the reconstruction of past environmental and climatic conditions using rodent assemblages, focusing on the archaeological sites of Azokh 1 Cave and Kaldar Cave, to enhance our understanding of human evolution within archaeological, paleontological, environmental, and ecological contexts. A taphonomic study was conducted to identify the nature and origin of the assemblage. Paleocological conditions were reconstructed using Habitat Weighting and the Bioclimatic model.

Results from the Azokh 1 Middle to Late Pleistocene layers suggest a relatively warm-temperate climate and an environment mainly composed of shrubland and steppe. Minimal changes were observed between the studied layers, indicating favorable conditions for human populations.

Furthermore, paleocological analysis of Kaldar Cave revealed lower temperatures and precipitation compared to present-day conditions during the Late Pleistocene, suggesting that hominin populations inhabited an environment mainly consisting of dry steppes with patches of forested areas.

In summary, the different methodologies used facilitated the identification of predators at the origins of the assemblages and the recovery of important palaeoenvironmental and palaeoclimatic information in Eurasia, especially in the Zagros Mountains of Iran and the Caucasus region. Additionally, regarding the paleobiogeography of our identified rodent species, which are mainly composed of taxa of Asiatic origin, it suggests that the Zagros and Caucasus mountains likely acted as a barrier for small mammals coming from Africa.

6 CENTERING THE PERIPHERY: NEW PERSPECTIVES ON THE CENTRALITY OF ARID ENVIRONMENTS IN THE ECONOMY OF CENTRAL EURASIA

Castro, Mariana (New York University (Institute for the Study of the Ancient World))

In Near Eastern and Central Asian archaeology, deserts have often been perceived as hostile environments unfit for human presence. This view promoted the development of various racist and inaccurate narratives concerning desert dwellers. In Central Asia, for example, Dependency Theory argued for the incapacity of mobile-pastoralists to thrive in their homelands while successfully maintaining sustainable and independent forms of subsistence, craftsmanship, and resource extraction. Taking the Kyzylkum desert in modern Uzbekistan as an example, this paper contests the view that deserts have been peripheral or remote places in the economy of regional and interregional exchanges, particularly in relation to settled, cosmopolitan areas of the pre-modern world. In reality, the Kyzylkum was an essential source of mineral resources to the surrounding oasis regions, especially copper and turquoise.

A perspective centering deserts and their peoples fits within the recent academic wave of scholarship focused on returning agency to nomadic and semi-nomadic groups in the archaeological record, and opens the dialogue for a more inclusive and complete view of past societies. It also challenges the core-periphery models often applied in Landscape Archaeology and highlights the role and resilience of mobile-pastoralists in shaping regional and interregional history. Pursuing a better understanding of these various issues within the arid landscapes of the former Soviet Union is particularly timely, especially if we consider the ancient and modern development of the so-called "Silk Roads" and the increasingly fundamental place of Central Asia in global historical narratives.

7 AGRO-PASTORAL LANDSCAPE FIRE SUPPRESSION IN THE STEPPES OF THE BRONZE AND IRON AGE SOUTHERN CAUCASUS

Cromartie, Amy (Cultures et Environnements. Préhistoire, Antiquité, Moyen Âge (CEPAM); Cornell University) - Khatchadourian, Lori (Cornell University) - Ménot, Guillemette (LGL-TPE, ENS Lyon) - Peyron, Odile (Institut Des Sciences De L'évolution De Montpellier (ISEM)) - Smith, Adam (Cornell University) - Badalyan, Ruben (Institute of Archaeology and Ethnography NAS Republic of Armenia) - Lindsay, Ian (Purdue University) - Palumbi, Giulio (Cultures et Environnements. Préhistoire, Antiquité, Moyen Âge (CEPAM)) - Joannin, Sébastien (Institut Des Sciences De L'évolution De Montpellier (ISEM))

Fire is a natural, frequently occurring disturbance in steppe grasslands and is essential for ecosystem maintenance. Today, humans living in the steppe grasslands of the Kasakh valley, Armenia, contribute to suppressing this natural fire regime through vegetation management practices like grazing, controlled burns, and haymaking. Holocene fire re-

conds from this region also record an active natural fire regime throughout the Holocene, which stops between 5500 and 2500 cal. BP (3500 - 500 BC) when Bronze and Iron Age communities moved into this region (Cromartie et al. 2020), raising questions about the role of past communities in fire suppression.

In this paper, we present new work completed from a wetland core taken from the Kasakh valley dating from 8500 cal. BP to the present to shed light on this phenomenon. We run a combination of proxies, including macro-charcoal, pollen, non-pollen palynomorphs, and paleotemperature biomarkers (brGDGTs), to reconstruct the fire, vegetation, agro-pastoral land-use, and climate history and compare the results to the settlement history. Together, we find that these communities utilized various vegetation management strategies to suppress the fire regime, including animal browsing/grazing, which may have begun as early as the Chalcolithic. However, humans did not act alone, with climate also significantly affecting vegetation turnover. Our paper highlights the need for historical contingent landscape histories that integrate the paleo- and archaeological sciences to understand the role of humans over time in fire-regime maintenance.

Cromartie, Amy, et al. "The vegetation, climate, and fire history of a mountain steppe: A Holocene reconstruction from the South Caucasus, Shenkani, Armenia." *Quaternary Science Reviews* 246 (2020): 106485.

8 SURVIVING IN THE SEMI-ARID REGION: THE HITTITES RESILIENCE PRACTICES IN ANATOLIA AT 2ND MILLENNIUM BC

Saskara, Agit (Protohistory and Near Eastern Archaeology)

Anatolia is a geography where the semi-arid climate and plateaus have existed in almost every period throughout history. It is known throughout history that very serious droughts have occurred in this geography. We can say that drought is a historical phenomenon of Anatolian geography. Founded in 1650 BC in the semi-arid Anatolian geography, the Hittites' ability to survive in this semi-arid geography for approximately 500 years should be perceived as a historical success in terms of human history. In this context, the Hittites implemented some practices to survive in the geography they existed in.

As a result of these practices, dams representing the earliest examples in the world were built for the first time in Anatolian geography 3500 years ago. Apart from the dams, water reservoirs-pools and silos, that is, grain storages, were built. The main question of the study: How did the Hittites survive in the semi-arid Anatolian geography with the techniques they developed thousands of years ago? What are these techniques? Finding answer(s) to these questions in the light of archaeological remains is the aim of the study. In this context, the human-environment and climate relationship are discussed with a historical example and aims to present a projection from today to the past.

9 DEMIC EXPANSION OF THE AGROPASTORAL SAKA AND WUSUN CONFEDERACIES/STATE (800 BCE TO 400 CE) IN SOUTHEASTERN KAZAKHSTAN

Chang, Claudia (Independent scholar) - Tourtellotte, Perry (INDEPENDENT SCHOLAR)

For the past 30 years we have in collaboration with our local Kazakhstani colleagues have directed surveys and excavations of Iron Age burial sites on the Talgar alluvial fan (535 sq km). We have recorded 1000 Iron Age burial mounds and 70+ settlements. Three Iron Age sites of hamlets, small and large villages from 0.3 sq hectares to 10 hectares have been excavated. Specialist studies in paleo-ethnobotany (phytolith and macro-seed recovery), zooarchaeology, and geomorphology. Hydrological and geomorphological studies indicate the use of stream channeling and check dams, possibly larger scale irrigation originating by at least 400 BCE and possibly earlier. We test the hypothesis that the spread of agropastoralism and pastoral transhumance took place across many alluvial fans along the Northern Tian Shan Mountains. This population spread across a series of alluvial fans may be similar to the "wave and advance model" proposed by Ammerman and Cavalli-Sforza (1984) for the Neolithic transition in Europe.

In contrast the Iron Age period in Eurasia has been characterized by the formation of the Saka state and nomadic confederacies based primarily on mobile pastoralism. The environmental conditions of rich chernozem soils on the alluvial fans served as ideal pockets suitable for rainfall, check dam, and larger-scale irrigation systems. Climatic conditions of warm and wet phases contributed to the growth of agropastoralism. The early nomadic states produces surplus agricultural and pastoral resources which served as a backbone for an aristocratic elite of nomads, apparent from the burial inventories found at kurgans such as the Issyk Golden Warrior. The economy of mixed farming and animal husbandry led to the rapid socio-political expansion of the nomadic Saka and Wusun states in the Semirechye (Zhetisu) region.

10 POPULATIONS OF THE CENTRAL ASIAN STEPPES AND REED BEDS OF THE AMU DARYA IN THE EARLY CENTURIES OF ISLAM

Rhoné-Quer, Camille (Aix-Marseille University; CeRMI; IREMAM)

The Amu Darya flows through vast areas of steppe and desert (Kara Kum and Kizil Kum). On its banks, the only naturally available vegetation are tugai and reeds. We will be looking at how the neighbouring populations have managed to make the most of the reed beds' resources (flora, fauna, etc.) to live and survive in this difficult environment. We will be focusing on the early Islamic period. Using data from written sources (Arabic and Persian texts from the medieval period, travellers' accounts from the 19th century), archaeology, palaeoecology, botany and archaeobotany, we will look at the adaptability of reeds to Central Asian climatic conditions (aridity, salinity, floods/droughts). We will also look at the uses to which reeds are put, both for wildlife (habitations/buildings, food) and for humans (location of reedbeds, consumption, construction, transport). The aim of this paper is to provide a better understanding of the role of reeds as an essential resource for agropastoral societies, whether sedentary or nomadic.

1123 TRANSIENT TRACES: UNEARTHING THE HIDDEN MATERIAL DIMENSIONS OF CONTEMPORARY MIGRATION

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Jungfleisch, Johannes (Ruhr University Bochum; Leibniz ScienceCampus "ReForm" Bochum) - Raeymaekers, Timothy (University of Bologna)

Session format: Regular session

In 2015 and 2016, the European 'migration crisis' saw the active involvement of journalists, scholars, and activists in documenting the border repression that characterized migratory journeys on the continent. Iconic images come to mind, such as people arriving by inflatable dinghies and living in makeshift camps, alongside the deployment of increasingly complex bordering infrastructures. Over time, these images have gradually faded, and media attention has shifted from the Mediterranean to other crises.

Nevertheless, migration from the Global South to Europe persists until today. This ongoing process gives rise to distinct material manifestations and traces, ranging from highly militarized border infrastructures to objects left behind on migration journeys and the life worlds of illegalized migrants residing in Europe and so-called 'transit countries.' Despite the growing scholarly interest in the social, political, and cultural sciences, the materiality of this phenomenon still tends to be under-researched, even in archaeology.

Therefore, this panel foregrounds the often-hidden material dimensions of illegalized migration through a transdisciplinary lens. The aim is to explore and discuss the multifaceted material realities faced and produced by migrants as they engage with territorial borders and various economic sectors while seeking refuge and a way to subsist. Our inquiry necessarily crosses formal-informal boundaries, such as between official refugee camps and informal settlements, as we seek to highlight the (material) infrastructures through which migrants' presences are actively differentiated, bounded, and governed.

For this purpose, the session will bring together scholars from diverse disciplines, addressing less visible stages of contemporary migration from a material perspective. On the one hand, we invite case studies examining the material manifestations of contemporary migration. On the other hand, we look for methodological and theoretical contributions, fostering discussions and ethical reflections on the complexities of studying lived material cultures from an inter- and transdisciplinary perspective.

ABSTRACTS

1 WALLING OUT ON THE U.S. - MÉXICO BORDER

McGuire, Randall (Binghamton University)

National borders disrupt things. They do not, however, do so simply as lines on a map. Lines on a map create the illusion of borders but they only become disruptive when nation states materialize the web of social relations and meanings that borders entail. In the 21st century, nation states have increasingly chosen to materialize their borders with walls. Nations have raised barricades of barbed wire, steel, brick, and concrete to provide security, control movement and deny agency to multiple transgressors including terrorists, smugglers and undocumented migrants. Walls, however, enable agency that the builders did not imagine or desire, and crossers continually create new ways to transgress and disrupt the purpose of the wall. In this on-going dialectic of fortification and transgression, both nation states and the transgressors rematerialize the border. We see this dialectic of disruption on the fortified U.S. - México border. Here the U.S. has constructed hundreds of miles of walls, fences and vehicle barriers and backed these up with armed officers, dogs, helicopters, drones, observation towers, and vehicle checkpoints. This material border forces migrants

into "hostile terrain" where they would be at "mortal danger" in the desert, and crossing the Rio Grande. In the cities the walls break bodies and assassinate crossers. Despite these efforts, transgressors make the border a fluid space of crossing that disrupts the tidy schemes of nation states.

2 "418 BOATS SENT = 20,900,000 \$": TRACING BORDERING AND BORDER-CROSSING PRACTICES IN THE EASTERN MEDITERRANEAN

Jungfleisch, Johannes (Ruhr University Bochum)

The Turkish west coast, overlooking the Aegean Island of Lesbos, is renowned for its stunning natural scenery. Centuries-old olive groves, interspersed with the characteristic Mediterranean macchia vegetation of evergreen bushes, adorn the rocky coastline, occasionally featuring small pebble bays. This picturesque coastal landscape plays a central role in the contemporary migration movement from various countries of the Global South to Europe.

Situated just a few kilometres from the Aegean islands, the Turkish west coast has long served as a departure point for migrant boats embarking on their journey to Europe. People on the move rely on different items during their travels, which they sometimes abandon for several reasons. Therefore, the ongoing migration has materially manifested in heterogeneous assemblages of objects left behind along Turkey's shores. These mundane objects and material remnants, often perceived and categorised as mere rubbish, may contain valuable information shedding light on lesser-explored stages of migratory journeys, such as the period of forced waiting on the Turkish west coast.

Despite their fragmentary and incomplete nature, the material remains of clandestine migration document the complex interactions between different actors as traces in their physicality. In this context, contemporary archaeology plays an important part: This discipline has developed a unique set of research techniques enabling researchers to analyse human behaviour based on the materials left behind. Consequently, in contemporary settings, the object-focused methodology of archaeology allows us to reconstruct past processes and events while maintaining an ethical distance from their occurrence.

Drawing on fieldwork conducted in Turkey and Greece in 2017 and 2023, this paper conceptualises migrant materials left behind on the Turkish and Greek coastlines as material traces of bordering and border-crossing practices. Through this analysis, I aim to unearth the undocumented histories entangled in the material remnants of migration.

3 ARCHEOLOGICAL INVESTIGATION OF REFUGEEBOATS AT LAMPEDUA

Wilts, Gesche (www.miss-jones.de)

Since 3 decades, Lampedusa is well known for being the goal of Refugees. Mainly African and Arabic people try to escape with boats and cross the Mediterranean Sea. On September 12, 2023, the mayor of Lampedusa declared a state of emergency. That day, 5.000 Refugees made their way to Lampedusa. Too much to handle on that little Island. At the same time the Archeological investigation team, Gesche Wilts and Jonthan Kündiger, was at Lampedusa. The project was about documenting the Boats of the Refugees with archaeological methods. This documentation shows the circumstances under which Refugees are coming to Italy. These circumstances did Change in Summer 2023. Since 2022 there is a new Form of Boat made out of metal, which has sometimes been used. In the middle of September 2023 when 10.000 People arrived at Lampedusa in just three days, these Metal boats, only built for escape, has been the most used Type of Boat.

The Documentation of these Boats show that they have Similarities and differences. Sometimes, it seems, that they are self-build. The boats are made of 1 mm thin metal plates welded together. The internal stiffeners are usually only attached with spot welds. These boats are life-threatening. Poorly made welds can break quickly. The boats are often overcrowded, so one wave can capsize a boat.

Sometimes saver wooden boats are still reaching Lampedusa. Based on the documentation, the question of status differences during the escape arises. Further investigations are planned: shipwreck research methods to investigate the safety of these boats and the analysis of the Objects found on Board, for example to research the drinking water supply on the escape.

4 ASSEMBLAGES, NOT OBJECTS: SURVEY METHODS AND THE ARCHAEOLOGY OF CONTEMPORARY MIGRANT JOURNEYS IN WESTERN SICILY

Schon, Robert (University of Arizona) - Blake, Emma (University of Arizona) - Wigodner, Alena (Princeton University)

In this paper we prioritize assemblages over individual artifacts as units of study in an archaeology of contemporary migrant journeys. In the summers of 2018-2019, a team of archaeologists from the Arizona Sicily Project conducted an intensive archaeological survey documenting traces of migrant landings along the coastline of Capo Feto, the closest point in Sicily to Tunisia. These traces included, among other things, discarded seawater-soaked clothes, Tunisian water and medicine bottles, and even an abandoned boat. Importantly, they clustered in discrete units that we

documented as “assemblages” each representing a single event: a successful landing. The entangled objects in these assemblages divulge aspects of the lives of the invisible and anonymous travelers in powerful ways. In contrast, a subsequent collection of the material on a sandy stretch of Capo Feto beach yielded further North African material – this time, though, in the form of isolates found among debris of all kinds, local and otherwise. These individual items, many of the same type as we found grouped together in the assemblages, were evidence of connection across the Sicilian Channel but not much else. They yielded no insights into the people who brought them, if indeed people brought them at all. What, then, do the assemblages we documented reveal? In contrast to the tragic stories of dangerously overcrowded ships, the content and topographic position of migrant assemblages reflect a specific type of journey – one that is targeted, and that relies on an intimate familiarity with the passage, the coastline, and the shallow marine shelf that all require expertise to navigate safely. Our results contribute to new understandings of how to interpret contemporary material culture in open mutable settings while at the same time humanizing the actors who left those material traces behind.

5 EFFACED AFFECTS: TRACING LESSER MATERIALS IN THE MIGRANT TRAIL

Simeonidis, Phevos (Durham University)

As multiple ‘crises’ of displacement and movement still spread across scholarly, journalistic, and activist work, so do spread the materials left behind by those crossing the borders, or die trying to. Living or dead, disappeared or recovered, bodies often carry with them the personal items of the persons on the move, or the materials they produced or used along the way. The notion of the “migrant trail”, as De Leon (2015) sets it in both temporal and spatial coordinates, is often brimming with these objects. Yet many remain unaccounted for.

In this paper, I wish to trace some of these materials, both of the living and the dead, that are deemed less important for public discourses on migration – or its management –. Using the materials as a method themselves, I will argue that their existence, or destruction, the effacing of their affective nature, greatly alters the realities of those that were once in proximity to them.

Drawing from activist and scholarly fieldwork in the island of Lesbos, Greece, and the river border of Evros/Meriç between Turkey and Greece, the physical or digital materials that the paper examines, are the ones that are often left behind, unassociated with the crossing.

In doing so, I wish not only to highlight the ethical complexities of studying these materials, as per the panel’s call, and their corresponding scholarly or activist culture that they allow, but also question how our perception of said materials is often limiting or enabling further research through their inclusion or exclusion from our gaze.

Finally, in dialogue with the notion of disappearability (Laakkonen 2022, 2023) the paper will enquire as to how we can trace back those materialities that are now effaced, and work towards a renewed sense-making of the realities of which they bore witness.

6 THEGAME PROJECT. ARCHAEOLOGICAL APPROACHES TO HOMING STRATEGIES IN MAKESHIFT CAMPS ALONG THE BALKAN ROUTE

Farina, Emma (University of Bologna)

The Balkan Route is the main overland migration corridor into Europe; stretching from the eastern Greek islands to western EU countries, each year thousands of refugees travers the route or ‘try the game’, as they refer to their journeys, constantly reshaping the route itself. Along the route refugees establish makeshift camps, informal and temporary settlements located in urban squats, isolated rural areas, or adjacent to official refugee camps; here refugees can rest, exchange information, and make arrangements to continue their journey. The interdisciplinary ERC research project ‘TheGame: Counter-mapping informal refugee mobilities along the Balkan Route’ aims at theorizing makeshift camps along the route as an ‘archipelago’ of interconnected settlements with a unique social and political life and at creating an ‘archive-in-progress’ documenting refugees’ experiences of the everchanging corridor. Within the project, archaeological methodologies are to be employed to investigate the material and spatial dimensions of the camps and contribute to the archive.

Makeshift camps are composed of recycled and re-adapted materials, thus yielding a specific material culture, and refugees often record their presence with graffiti. As the camps undergo phases of use and abandonment due to cyclical population fluctuation and can permanently be evicted by law enforcement, the documentation of the camps is a pressing issue to contrast the State-enforced obliteration. These are fundamental spaces to understand informal mobilities and refugees’ agency, as makeshift camps are born out of refugees’ appropriation and reshaping of spaces. This research aims at documenting and studying makeshift camps along the Balkan Route in their different phases of use and abandonment, investigating how during their journeys, refugees can ‘home themselves’, to recreate a familiar environment, through material culture and the spatial dimension, simultaneously affirming their agency and marking their presence in the landscape.

7 MIGRANT LABOUR DORMITORIES IN GREECE: TRACING MATERIAL TRANSFORMATION FROM ABJECTNESS TO RESISTANCE

Kukreja, Reena (Queen’s University)

It is estimated that over 90 percent of labour in Greek agriculture is done by migrant workers. A majority of South Asian migrant men, the focus of my presentation, are “undocumented. Greece’s migration and temporary labour regimes forces them to labour precarity that is defined by harsh labour conditions, low and withheld wages, and unregulated hours of work (Kukreja 2019, 2021, 2023b). The migrant workers are forced to live in makeshift or repurposed housing – recycled plastic and cardboard tents (barangas) or farm sheds and abandoned warehouses – these lack the basics of sanitation and other amenities of life.

This paper focusses on the lived material culture of migrant housing by focussing on the barangas in Manolada. Instead of discussing, in length, the much acknowledged dehumanized materiality of migrant existence evident through the recycled plastic and cardboard housing that nearly 15, 000 Bangladeshi migrants are forced to live in during the strawberry growing season in Manolada, the paper examines the role of memory and imagination in shaping migrant engagement with material objects and spaces. Intertwining the concept of “travelling memory” (Erell 2011) with resistance theory, I argue that the migrant workers, placed on the margins of Greek society, articulate their resistance by “humanizing” spaces of alienation and abjectness. Through individual and collective creative acts, their living memory and nostalgia for home and communal existence infuses new meaning to material objects and spaces. I illustrate this by using examples of memory objects that appear mundane and everyday but are suffused with memories of life elsewhere. By transforming physical spaces with vegetable gardens, swings, and ethnic markets, or as spaces for leisure and communal joy such as Sufi singing, the Bangladeshi migrants resist the forced invisibilization and abjectness that bordering regimes seek to enforce on their racialized and “illegal” bodies.

8 FAKE BRANDS, PRAYER CARPETS, AND STREET FOOD: TOURIST SPACES AS SITES OF MIGRANT’S BORDER RESISTANCE

Traber, Janine (University of Cologne)

Tourism provides migrants from African countries with varied ways of making an income. After arriving “irregularly” in Europe, formal employment is usually not an option. Tourism on the other hand relies heavily on undocumented labor, from construction work, hotel cleaning, beach souvenir vending, to sex work in and in front of nightclubs. In this talk, I argue that tourist spaces become amplifiers of otherwise erased materiality. Regarding them as hybrid and cosmopolitan non-places, in which by their nature nothing is authentic or abnormal, they produce both discursive and material manifestations of the border as well as subversive material contestations of it. The things that are usually kept secret or made invisible to veil the migrant status before the public eye can become a valuable currency in competitive attention economies of mass tourist sites. The large numbers of people passing through and the fleeting and quirky nature of the encounters seemingly grant security while at the same time producing the exploitative capitalist economic conditions that form the base of migration incentives. While on the one hand, the intersection of tourism and migration often produces problematic tourist performances against the migrants, they may on the other hand also lead to the formation of politically engaged civil communities. In several examples from a multi-sited research on Senegalese migration to Europe, I am going to discuss the potential of archaeological methods to uncover and document how migrants from Senegal negotiate and counter the bordering strategies of European tourists.

9 (FORCED) MIGRATION AND AMASSED DISPOSSESSIONS: CONDITIONS AND CONSEQUENCES

Yi-Neumann, Friedemann (University of Helsinki)

As people move away from devastated places, they leave behind tons of debris from their former properties. As one crosses borders without paper, it may be likely that it is necessary to discard further personal items. As people are kept in protracted limbos by border regimes, this regularly causes a series of disposessions (Hicks & Mallet, 2019; Khosravi, 2018). Some migration anthropologists have unearthed the relevance of material culture. (Levin, 2019; Dudley, 2010; Basu & Coleman 2008). The perspective proposed in this contribution broadens classic takes on things by focussing on disposessions as a material phenomenon.

First, this paper demonstrates how disposessions as a material phenomenon negate the means of social reproduction in the broadest during (forced) migrations and in protracted displacement (see, e.g., Stein, 2015; Kiddey, 2017; Holmes & Ehgartner, 2020). Second, the author shows that disposessions can take effect in various ways, direct and indirect ways, from the blunt violence in warzones to subtle decisions on asylum and illegalization and that the more indirect disposessions are less likely to be considered disposessions. Third, this contribution will elucidate how repeated exposure to dispossession violence causes destructive accumulations and will provide ethnographic examples of how disposessions cause chronic ‘all-taking’ threats to people’s existence and their political economies of being.

DISCUSSING DISPLACEMENT: MATERIAL CULTURES OF REFUGE IN THE PITT RIVERS MUSEUM

Khan, Hadiqa (University College London; Pitt Rivers Museum)

European museums have actively participated in discussions surrounding displacement, particularly in light of the on-going migration from the Global South to Europe. Despite their engagement with Europe's refugee 'crisis', displaced populations are often framed solely within the context of crisis, with discussions and exhibits being temporary and fleeting. More often than not, material culture from forced migrants and refugees is collected, displayed in temporary exhibitions, and then largely forgotten in over-packed museum store-rooms.

This paper applies an archaeological lens to examine the Pitt River Museum's interactions with displaced individuals and objects, viewing the museum as an archaeological site and its collections as assemblages. Through an analysis of 35 years of collecting practices, recent exhibits, and community-led initiatives, this paper explores how the museum has approached its engagement with refugees and forcibly displaced communities.

Using three case studies from the Pitt River Museum's collections (a thob from Palestine, token 'currency' from the Katsikas Refugee Camp in Greece, and a piece of the Calais border fence), this paper argues that studying objects collected from sites of displacement and displaced individuals not only sheds light on the latter's treatment, but also serves as a means to scrutinize broader inequalities. The paper emphasizes the need for museums to move beyond transient discussions and foster sustained engagement, contributing to a deeper understanding of displacement, its socio-cultural implications, and the multifaceted narratives embedded in the artifacts of forcibly displaced populations.

1124 CHANGING LAND USE STRATEGIES AT HIGH MOUNTAIN AREAS IN EUROPE SINCE THE NEOLITHIC

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Gassiot Ballbè, Ermengol (Departament of Prehistory. Universitat Autònoma de Barcelona) - Antolin, Ferran (German Archaeological Institute; Prähistorische und Naturwissenschaftliche Archäologie (IPNA), Universität Basel) - Clemente Conte, Ignacio (Departament d'Arqueologia i Antropologia, IMF-CSIC)

Session format: Regular session

In the last 2 decades archaeology in European high and middle mountain areas has undergone a remarkable development. Numerous research projects have provided information regarding new sites and have uncovered long occupation sequences, often in areas where virtually no archaeological evidence was known. Despite these advances, the understanding of the processes of occupation of these high and medium mountain areas is generally based on a fixed premise, namely that the main purpose of the frequentation of these territories from the Neolithic onwards was their exploitation as pastures for livestock.

Numerous indications indeed confirm the presence of various forms of livestock farming in these areas. However, the progress of archaeological research also shows possible indications of other activities, such as agricultural practices, from the Neolithic onwards in altitudinal belts located at and above the current higher altitude villages in various European mountain ranges. Some excavations have yielded a considerable volume of carpological remains, together with evidence of processing and storage. Others have documented, through microbotanical remains, residues or traces of cereal exploitation. In some sedimentary cores, e.g. from lakes and peat bogs, the sign of possible cultivation is also worth of consideration. In some contexts, traces of terraces and even ancient cultivation fields are being documented using geoarchaeological techniques.

This evidence invites us to rethink the changing forms of occupation of medium and high mountain environments and to what extent, beyond an almost exclusively livestock specialisation, agriculture played a role in these processes in some periods. Papers presenting case studies or regional approaches either with new data or modelled scenarios are welcome, as well as ethnographic or more theoretical papers on human-mountain interactions through time.

ABSTRACTS

1 GEARCHAEOLOGICAL TEST PITS: A MULTIPROXY METHODOLOGY BASED ON A PALEOSOILS STUDY APPLIED TO THE RECONSTRUCTION OF CULTURAL LANDSCAPES IN MOUNTAINS

Rodríguez Antón, David (Autonomous University of Barcelona) - Revelles, Jordi (Catalan Institute of Human Palaeoecology and Social Evolution) - Andreaki, Vasiliki (Autonomous University of Barcelona) - García Álvarez, Salvia (Polytechnic University of Madrid) - Cunill, Raquel (Autonomous University of Barcelona) - Obea, Laura (Autonomous University of Barcelona) - Bonet, Anna (Autonomous University of Barcelona) - Gassiot Ballbè, Ermengol (Autonomous University of Barcelona)

During the last decade, a multiproxy methodology focused on the identification of different human actions and activities documented in mountain paleosoils has been developed. This methodology is based on the characterization of ancient paleosoils formed during the Holocene in mountain valleys, usually, in terraces from alluvial plains located in glacial basins.

The test pits methodology integrates three complementary approaches: (1) Chronometry: which is based on the taxonomical identification of stable sedimentary woody charcoals dated using the ¹⁴C AMS technique; (2) Geoarchaeology: which involves the identification and characterization of palaeosoils and stratigraphy through the study of thin sections with a petrographic microscope, FT-IR spectrometry, geochemical quantification of organic matter, phosphorus and others items; (3) Archaeobotany: that is focused in the reconstruction of paleolandscapes and human actions based in the quantification of different and complementary plants and algae micro-remains such as pollen, NPP, phytolith, diatoms, and micro-charcoals; and plants macro remains such as carbonized woods, seeds, leaves, and pedosedimentary charcoals.

The method was tested in the National Parc of Aigüestortes and Estany de Sant Maurici, located in the axial central Pyrenees ranges of Lleida (Spain). Specifically, it has been applied in Aigüestortes' wetlands from the glacial basin of Sant Nicolau valley, in a fir forest of the subalpine stage around 1800 m a.s.l.

The study of the Aigüestortes test pit indicates that the paleosol formed in the mid-Holocene, dated between 7.200 and 6.800 calBP, was the result of recurrent human activity in the area based on firing, grazing, and possibly some cultivation practices.

2 FROM HIGH SOILS TO HIGH GROUND - POTENTIALS OF SOIL GEOCHEMISTRY IN RECONSTRUCTING PAST HUMAN-ENVIRONMENTAL RELATIONSHIP IN HIGH MOUNTAINOUS AREAS

Laaha, Valentina (Department of Prehistoric and Historical Archaeology - University of Vienna) - Kowarik, Kerstin (Austrian Archaeological Institute - Austrian Academy of Sciences) - Brandner, Daniel (Natural History Museum Vienna) - Scholz, Roman (Romano-Germanic Commission of the German Archaeological Institute) - Reschreiter, Hans (Independent Researcher) - Hofmann, Kerstin (Romano-Germanic Commission of the German Archaeological Institute)

By dwelling, farming, herding, crafting, and generally living people have left elemental traces in the ground. These chemical fingerprints conversely hold the potential of identification and reconstruction of human activity. Based on their ability to hold such information ('soil memory') soils over the last years became continuously more recognised as valuable archives of human presence and action.

However, so far little is known of the potentials of soil geochemistry studies regarding the reconstruction of past (land) use and spatial analysis of high mountainous areas in the Alps. To build a basic understanding of the chemical composition of alpine meadow soil and 'memorised' human impact on it, a pilot study was carried out on the Dachstein plateau near Hallstatt (Austria).

This landscape has seen diverse human activity at least since the early Bronze Age. So, most recently we conducted geoarchaeological investigations in the microregion of the Grafenbergalm. A coring raster was established on the basis of former characterisations and preceding geomagnetic measurements. The sampling area thereby included the remains of an alpine hut and its near-site area. Soil samples were extracted with a hand corer and analysed for qualitative and quantitative elemental composition using energy dispersive X-ray fluorescence spectrometry (ED-XRF). Data analysis included interpolated elemental mapping and multivariate modelling. This will provide a baseline for future geochemical work on the Dachstein plateau, the Alps, and mountainous areas in general. Further, it will contribute to the creation of a (geo)archaeological toolbox to identify and reconstruct human activity and human-environmental interaction over time in medium and high alpine areas.

The geochemical work is part of a wider research programme focused on the complex human-environment interactions in this fragile landscape. It thereby brings together data from lake sediments, bogs, keyhole excavations, and further geoarchaeological analysis.

3 THE NEOLITHISATION OF THE DOLOMITES (EASTERN ITALIAN ALPS): THE CASE STUDY OF VALLE DI LAMEN (FELTRE, VENETO)

Carrer, Francesco (Newcastle University) - Cavulli, Fabio (Universita' degli Studi di Napoli Federico II)

Valle di Lamen is a narrow and steep valley in the Southern Dolomites of the Belluno province (Eastern Italian Alps), that connects broad valley of Feltre to the uplands (around 2000 m). Despite its fairly inhospitable look, this valley has provided solid evidence of human occupation throughout history. Surveys and excavations in the 1990s showed that large rockshelters near the valley bottom, few hundred meters above the sea level, were used by agropastoral groups since the 5th millennium BC. Recent research carried out by the authors of this paper shows that even more remote rockshelters, located above 1000 m of elevation and known as "Ripari Alti" ("High Shelters") were occupied in the same period. Faunal assemblages indicate the presence of domestic and wild animals, and grindstones might suggest plant processing activities at the site. The excavation of Ripari Alti, alongside the other archaeological evidence available for Valle di Lamen, provide interesting data to understand neolithisation process in this area of the Dolomites. On the other hand, a lot of questions remain unanswered: What was the function of the Ripari Alti? What type of activities were carried out? Was it a seasonal or a permanent site? What was its relationship with the lower rockshelters and the other late-neolithic sites of the valley of Feltre? The continuation of the archaeological excavation and the analysis of the finds will shed new light on early farming practices in this marginal sector of the Eastern Alps.

4 UNDERSTANDING LAND USE CHANGE IN THE NEOLITHIC OF THE CENTRAL PYRENEES (5600-2100 CAL BCE). SPATIAL MODELLING OF BIOCLIMATIC BELTS

Salvador-Baiges, Guillem (Universitat Autònoma de Barcelona) - Gassiot-Ballbè, Ermengol (Universitat Autònoma de Barcelona)

The climate of high mountain areas is not only markedly seasonal, but it also changes with altitude. This fact causes changes in vegetation and habitats and, consequently, it can affect the potential uses and resources of the territory.

It has not been until a few decades ago that the Central Pyrenees have attracted the attention of archaeological research. Due to its biogeographical conditions, this region was usually considered a marginal and unsuitable area for habitation during most of the Prehistory times and, exceptionally, a Summer grazing area. However, in the last decades several Neolithic settlements (5600-2100 cal BCE) have been found and documented along the mountain range and nowadays, the economic strategies followed by human groups in this period in the Central Pyrenees are under debate. There are two main hypotheses: one of them suggests that the Pyrenees were occupied on a seasonal basis in Summer by groups with long-distance mobility from the beginning of the period; the other one proposes that early Neolithic communities practised a diversified economy, combining both small-scale agriculture and pastoralism.

This paper addresses this debate by analysing the settlement pattern of Pyrenean Neolithic sites in different chronological phases taking into account their location in different altitudinal belts and landforms; our final goal is to be able to relate the results of the analysis to the possible strategies and economic activities practised by these groups.

The Rivas-Martínez bioclimatic classification, combined with palaeoclimatic data, has been used to spatially model altitudinal belts at different times during the mid-Holocene. This approach provides a more precise understanding of which areas were used by early agro-pastoral groups and helps to detect changes over time. Together with orography, it is used to understand variations in the location of sites over time and to infer possible changes in the land-use.

5 PLANT FOOD ECONOMY IN MONTANE ZONES DURING PREHISTORY: NEW ARCHAEOBOTANICAL DATA FROM THE CENTRAL PYRENEES

Antolin, Ferran (Deutsches Archäologisches Institut; University of Basel) - Obea, Laura (Universitat Autònoma de Barcelona)

Human settlement in the eastern and central Pyrenees during prehistory, as well as in historical times, has been systematically investigated in several areas. This has led to novel and rich datasets including the location of new settlements, animal sheds, hunting sites, etc., and to a better understanding of the use of different mountain zones over time. Despite these advances, the methodology used in each study area within the Pyrenees differ slightly between teams, leading to different interpretations of the nature of the settlements. While agricultural practices in the Neolithic in the eastern Pyrenees seem well documented, there is some discussion on the use of settlements by early farming societies in the central Pyrenees, either seen as purely herding sites or longer-lasting occupations with mixed economies.

Botanical macroremains from a test trench excavated in 2013 in Coro Trasito confirmed that also in the central Pyrenees, evidence for local agriculture above 1500 m a.s.l. for the 5th millennium cal. BC was worth considering. For this talk, the analyses of the test trench will be complemented with the study of intensive surface sampling at the same site in later campaigns, as well as new data coming from Obagues de Ratera. Our goal is to discuss plant economy in

the area through time, considering the different chronological periods identified at both sites, from the Mesolithic to the Bronze Age.

6 A SEASONAL OR PERMANENT SETTLEMENT? STUDY OF LIVESTOCK MANAGEMENT STRATEGIES IN THE PYRENEES OF THE EARLY NEOLITHIC AND BRONZE AGE

Mata Ferrer, Sergi (Department of Prehistory, Autonomous University of Barcelona) - Sierra, Alejandro (Department of Prehistory, Autonomous University of Barcelona) - Rey Lanaspá, Javier (Departamento de Presidencia, Interior y Cultura, Gobierno de Aragón) - McGrath, Krista (Institut de Ciència i Tecnologia Ambientals (ICTA - UAB), Autonomous University of Barcelona) - Saña Seguí, Maria (Department of Prehistory, Autonomous University of Barcelona)

The acceptance of agricultural activities in the Pyrenean communities dates back to the second half of the 6th-millennium cal. BC., when the first signs of agriculture and livestock began to appear, especially in caves and shelters strategically located along the mountain range. An example is the cave of Coro Trasito (Tella-Sin, Huesca), a key site in studying the beginnings of animal livestock in the Pyrenees and the incipient livestock farming in the high mountains.

To continue the archaeozoological study developed previously, carrying out biomolecular studies using stable isotopes on teeth will allow us to know the livestock management strategies from the study of the patterns of mobility, reproduction and feeding of the animals of these first herds of the Early Neolithic and Bronze age. Also, taking into account the morphological similarity of sheep and goats, the application of the ZooMS methodology (method developed in the framework of paleoproteomics - Zooarchaeology by Mass Spectrometry) will allow expanding the resolution of the taxonomic classification, permitting us to consider the composition of the herds and the different animal productions in the high mountains. This will allow a more exhaustive study of the repercussions that animal management had on Early Neolithic and Bronze communities, shedding light on aspects such as the characterisation of settlement dynamics, the subsistence patterns and the role of livestock.

Based on these analytical approaches, it will be possible to conclude what type of livestock farming was carried out during the Early Neolithic in the Pyrenees and, consequently, what type of occupation took place in the cave.

7 LANDSCAPES OF POWER: CAPRINES IN THE PASTORAL STRATEGIES OF LOCAL ELITES IN MEDIEVAL PROVENCE

Unsain, Dianne (Stockholm University) - Hegarty-Morrish, Patrick (Trinity College, University of Oxford)

The importance of domestic caprines in the subsistence economy of the medieval Mediterranean, particularly in southern France (10th-15th centuries), is well established. Historical and zooarchaeological research places them as the main source of meat in the cities and towns of the region from the 13th century onward. However, little is known about the role of the ruling elites in this specialisation, especially their motivations and strategies for exploiting and controlling not only herds but also pastoral areas.

This paper is based on two complementary approaches: a zooarchaeological study of a series of sites in south-eastern France, occupied from the 10th to the 14th century. The sites include peasant settlements, garrisons, castles and towns. The diversity of socio-economic and chronological contexts allows a synthetic approach on a regional scale.

The second approach is based on the analysis of local textual archives. These include the town customaries and legal documents in communal archives, notary records, and the accounts of local officials. Here, domestic caprines appear among the animals kept by local elites, and the same time, this village-level elite sought new rights to formalise their rights to pasture caprine and extract revenue in caprine or sheep and goat's cheese from peasant neighbours.

This research highlights a radical change in the economic strategies of the Provençal elite towards caprine herding from the 13th-14th centuries onwards, with major repercussions for the entire community. These changes had a lasting impact on the economic relationships between town and country, the strategies by which village communities regulated pastoral activities on their territories, and on the increasingly caprine-shaped environment.

8 BASQUE PASTORAL SITES IN MODERN AND CONTEMPORARY TIMES: BETWEEN ARCHAEOLOGY, HISTORY AND ART HISTORY

Le Couedic, Melanie (Universite de Pau et des pays de l'Adour ITEM UR 3002) - Rozier, Hadrien (Centre d'Études Supérieures de la Renaissance UMR 7323) - Champagne, Alain (Universite de Pau et des pays de l'Adour ITEM UR 3002) - Heiniger-Casteret, Patricia (Universite de Pau et des pays de l'Adour ITEM UR 3002)

The aim of this paper is to characterise the materiality of pastoral sites in the Basque and Béarn regions in order to shed light on the way in which agropastoral societies in the Pyrenees appropriated the mountains over the long term. At the crossroads of archaeology, art history and anthropology, the aim is to analyse the results of inventories and excavations in order to establish a chrono-typology of the assemblages studied for recent periods. Particular attention

will be paid to the construction methods used to build the dwellings - frame and roofing - and to the way in which they were assembled with the structures used for parking. Written sources will also be used to examine the huts mentioned in land grants, sales and inheritances from the late Middle Ages onwards. Looking beyond the site, an ethnoarchaeological study of the routes taken will look at the space between sites, the space used, travelled and limited. Finally, comparisons will be made with a view to highlighting the specific features or common traits of these Basque and Bearn buildings with the rest of the pastoral corpus in the Pyrenees, and more widely in the south.

9 FROM GRAND NARRATIVES AND DOWN TO EARTH - AND BACK AGAIN? HISTORICAL AND ARCHAEOLOGICAL APPROACHES TO TRANSHUMANCE IN WESTERN NORWAY

Dahle, Kristoffer (Møre & Romsdal County Council; NTNU University Museum)

The origin and development of the Norwegian shieling system has been widely debated, both within history, ethnography, archaeology and place name studies.

In 1989, the French geographer Michel Cabouret suggested a relative chronology. Based on three commonly used terms for these pastoral sites, and the spatial distribution various place names, he suggested a stepwise and evolutionary development. From open and temporarily used milking sites (støl) in the outlands, some were used more regularly, with dwellings (sel) and dairy production, and finally evolved into more complex and farm-like settlement (seter). Today, 35 years later, numerous shieling sites across Western Norway have been surveyed archaeologically, but few are yet excavated.

In my current PHD, I have employed a range of methods to try to understand the origin and development of this transhumant system, including quantitative studies of both onomastic, historical and archaeological material, geophysical and archaeological fieldwork, and geoarchaeological methods such as paleobotany, entomology, micromorphology, pOSL, pXRF, aDNA and isotope analyses. Could Cabouret's suggestion still be holding water?

10 PREHISTORIC LAND USE IN SOUTHERN CENTRAL PYRENEES HIGH MOUNTAIN AREAS: CHANGING OUR PERSPECTIVE?

Gassiot Ballbè, Ermengol (Department of Prehistory, Universitat Autònoma de Barcelona) - Barba Pérez, Marcos (Department of Prehistory, Universitat Autònoma de Barcelona) - Clemente Conte, Ignacio (Institución Milà y Fontanals. Consejo Superior de Investigaciones Científicas) - Díaz Bonilla, Sara (Department of Prehistory, Universitat Autònoma de Barcelona) - Garcia Casas, David (Instituto de Ciencias del Patrimonio, Consejo Superior de Investigaciones Científicas) - Mata Ferrer, Sergi (Department of Prehistory, Universitat Autònoma de Barcelona) - Obea Gómez, Laura (Department of Prehistory, Universitat Autònoma de Barcelona) - Rodríguez Antón, David (Department of Prehistory, Universitat Autònoma de Barcelona) - Salvador Baiges, Guillem (Department of Prehistory, Universitat Autònoma de Barcelona) - Sierra Aja, Alejandro (Department of Prehistory, Universitat Autònoma de Barcelona)

In recent years, archaeological research has confirmed the uninterrupted human occupation of the mid and high mountain areas in the Pyrenees since the Mesolithic period. Successive surface surveys and non-invasive archaeology have made it possible to define extensive archaeological sequences and maps of the geographical dispersion of archaeological sites. In addition, the excavation of some of these sites has provided increasingly detailed intra-site information. In several cases, research in Pyrenean mountain areas integrates archaeology into broader interdisciplinary projects with palaeoenvironmental sciences.

As a result of all this, we now have a considerable amount of data which allows us to review the archaeological view of the human occupation of the high mountains over time and to reconsider is the development of the first livestock farming communities. From an archaeological point of view, we usually assume that the mountains, and especially the high mountains, were almost exclusively livestock areas and, at most, suppliers of raw materials. The continuity in the occupations of some sites and the confluence of sites in certain places could support this premise: same occupied spaces, same activities done. In this way, it would even be possible to trace back to the Neolithic the origin of some practices present up to the 20th century, such as transhumant farming.

However, the reality is much more complex. A detailed analysis shows that the locations of archaeological sites vary over time, for example, in relation to optimal paths or grazing areas. In parallel, intra-site studies show increasing evidences that point, for example, in the Neolithic and Bronze Age, to the possible existence of agricultural practices in these spaces. This presentation presents a brief synthesis of recent information on recent Prehistory in the southern central Pyrenees analyzing to what extent this data challenged the traditional paradigm on the land use during these periods.

1127 PLACES OF THE LIVING AND PLACES OF THE DEAD: THE RELATIONSHIP BETWEEN SETTLEMENTS AND BURIAL SITES IN CENTRAL ASIA

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Stanco, Ladislav (Charles University, Prague) - Lhuillier, Johanna (CNRS, Lyon)

Session format: Regular session

In the archaeology of Central Asia, careful attention has traditionally been paid to the research of important settlements and, more recently, to their interrelation and settlement dynamics. The sites of the living are thus very well known. To a large extent, this is also true for the places of the dead, at least in some historical periods. What is lacking for the moment is the linking of these two worlds, the understanding of the reciprocal spatial and ideological relationship between burial sites and settlements. All this is further complicated by the different patterns of behaviour and customs of sedentary and (semi-)nomadic societies, which met and changed regularly throughout prehistory and history in Central Asia.

In this session, then, we would like to ask how the living dealt with their dead, how significantly they sought to separate their space from their own, and also how and why these customs have changed throughout history. The key here is the meeting of steppe and sedentary, local and newcomer, near and far cultures in a mix that has no parallel in other regions.

We would therefore like to stimulate reflection and provoke discussion on the following questions:

How were the burial grounds organized in relation to the settlements?

In what cases, on the contrary, and why, is there no separation between the two spaces?

What is the spatial relationship of burial or funerary sites to the surrounding landscape?

What are the methodological possibilities and limits of understanding the spatial organization of burial sites?

How is this type of archaeological record affected by human interventions in the cultural landscape?

We also welcome partial reflection and problematization of phenomena such as the so-called kurgans and Zoroastrian dachmas in archaeology of Central Asia.

ABSTRACTS

1 RECONSTRUCTION OF THE EVOLUTION OF GONUR DEPE'S MAIN NECROPOLIS DURING THE MIDDLE AND FINAL BRONZE AGE (2250 - 1500 BC)

Hut, Camille (Université Paris 1 Panthéon-Sorbonne)

The Bronze Age in southern Central Asia inaugurated a significant change in the funerary landscape of proto-urban settlements. The topographical distinction introduced by the appearance of 'extramural' funerary spaces, as opposed to burial grounds within settlements attested since the Chalcolithic, raises the question of the structural, social, and ideological evolution of this society, reflected in the distinction between a world of the living and a world of the dead. Regarded as the capital of Margiana, and possibly of the Oxus Civilization, Gonur Depe is an emblematic site of the new funerary system prevailing during the Middle and Final Bronze Age (Namazga V - VI).

Located 200 meters west of the Palace of Gonur Depe, the city's Main Necropolis is one of the few known 'extramural' burial grounds, constituting a world of the dead distinct from that of the living. Analysis of almost 3,000 graves from the necropolis reveals an internal organization and spatialization of funerary practices that reflect the evolution of the symbolic system, as well as the socio-cultural and economic changes of the NMG V and VI periods. Over 700 years of occupation of this necropolis have provided a chronological record of the use of this sepulchral area by the community of the living of Gonur Depe.

The reconstruction of the necropolis and the practices associated with it, based on data from the excavations and the archives of the Margiana Archaeological Expedition, lays the methodological foundations, objectives, and biases for the spatial reconstitution of the relationship between the living and their dead.

2 ALWAYS WATCHING OVER US. BURIALS IN THE TAZABAG'YAB CULTURE AND THEIR INTERACTION WITH THE LANDSCAPE

Schreiber, Finn (Independent, Berlin)

Funeral monuments such as kurgans are not only a visible sign of commemoration and the (implied) significance of the deceased, but also a symbol of a community and its presence in the landscape. In order to be visible, they were often built on elevated ground or along ancient pathways. Graves are therefore part of the cultural landscape and can often provide insights into the structure of a microregion.

Ancient Khwarazm in the Late Bronze Age was a borderland between northern steppe-based Andronovo-Srubnaya groups and southern "oasis cultures". The local sites are part of the Tazabag'yab culture. Kokcha 3 (Turtkul district, Uzbekistan) is the only excavated burial site of this culture. It is a large cemetery with similar-looking graves on a small plateau opposite a contemporary settlement. Different body postures for males and females have been documented as well as two types of double burials. There was also a very limited number of grave goods.

Analyses of the Kokcha 3 burial site revealed a unique pattern of gender zones: Men were buried at the edge and women in the center of the cemetery. Between them there were double graves. Although grave goods were minimal, different social roles can be seen in the cemetery, which are expressed in the spatial position of the grave.

The men's burials close to the plateau's edges were probably marked and visible from some distance. They could have had a representative function for the community. Since male burials are mostly found on the eastern edge facing a small valley, we can reconstruct a path leading to the nearby settlement. Male burials should therefore be seen primarily by visitors. The results reveal a unique way of interacting between the burial site and its surroundings and even provide insight into the internal structure of its community.

3 THE DEAD AMONG THE LIVING: HUMAN REMAINS IN IRON AGE SETTLEMENTS IN CENTRAL ASIA

Lhuillier, Johanna (CNRS)

While Iron Age settlements are now well known in Central Asia, the same cannot be said for burial sites. No necropolis has been identified, and excarnation seems to have become the predominant practice. Both recent excavations and older publications show, however, the presence of human bones at the very heart of settlements throughout the Iron Age sequence (ca. 1500-300 BCE). In this paper, we will review the different types of deposits identified: scattered bones, sometimes showing traces of excarnation, body parts still in connection, isolated and atypical burials. We will question their location and their meaning for the inhabitants of the sites as well as whether these are simple fortuitous deposits or whether they demonstrate some intentionality.

In the foothills of the Kugitang mountains in southern Uzbekistan, recent discoveries of pseudo-kurgans in the immediate vicinity of Early Iron Age sites might suggest the existence of places dedicated to the open-air exposure of the dead. We will examine this possibility, taking a step aside from the widespread hypothesis of the development of Zoroastrianism.

4 BURIALS IN THE FOOTHILLS: NEW BARROW SITES NORTH OF THE AHANGARAN VALLEY AND A PLAN FOR THEIR STUDY

Leloch, Michal (University of Warsaw)

Due to their difficult, specific conditions, mountain areas are still only marginally recognised as archaeological sites throughout the world. The study of mountainous areas requires complex work logistics and brings disproportionate results. In order to understand the dynamics of how human communities functioned in the past in such a unique environment, it seems essential to first recognise the settlement of the foothills.

More than a dozen years of research by the Warsaw University expedition in the foothills of the Tien Shan, north of the Ahangaran valley in Uzbekistan, have yielded numerous finds that are not chronologically related to the purpose of the projects carried out so far. Excavations at Palaeolithic sites have revealed many burials dated from the Bronze Age to the Middle Ages. At the same time, surface surveys have revealed numerous barrows that stand out in the landscape. The picture of the area as we know it today is completed by sites with petroglyphs few kilometres away in the high mountains.

We believe that these accidental discoveries offer a perspective for understanding the patterns of use of the foothills and, in the longer term, their links with the high mountain sites. The paper presents a plan for an interdisciplinary project as a first step in the search for these connections. The work to be carried out aims to identify, excavate and date as many burial sites as possible in the area of several valleys. The aim of the presentation is to stimulate discussion on the planned methods and the validity of the project.

5 RIVERS FOR THE LIVING AND HILLS FOR THE DEAD? RE-EVALUATING THE KURGAN MOUNDS OCCURRENCE IN THE EASTERN KUGITANG PIEDMOUNTS, UZBEKISTAN

Havlík, Jakub (Institute of Classical Archaeology, Charles University)

Since 2014 the Czech-Uzbekistani archaeological mission has been systematically mapping and investigating kurgan mounds in the eastern Kugitang piedmonts, southern Uzbekistan. Up to 2022 more than four hundred of stone- and earth-made mounds were mapped, showing the significance of this phenomenon in the formation of the local cultural landscape. Predominantly by means of location analysis, this paper attempts to evaluate the occurrence of the kurgan

mounds in relation to both the characteristic natural environment of the piedmont steppe and features of the cultural topography (i.e., settlements and pathway network). The analysis shows a specific choice of the location of the kurgan mounds, giving a clear preference for flat river terraces at middle altitudes. The location of the kurgan mounds does not appear to be significantly conditioned by the proximity of a settlement of any particular dating. On the other hand, the kurgan mounds tend to occur in the vicinity of the (traditional?) pathways recorded in the Soviet period. Therefore, this study proposes the relationship to mobility as a determinative factor in the location choice. Together with the study of mound morphology and data from excavations of selected individuals, this analysis suggests that the emergence of kurgans in the eastern Kugitang piedmonts was not related to a single chronological horizon. Instead, the formation of the recorded mound landscape probably covered a wider period stretching between the Early Iron Age and the Early Middle Ages.

6 FUNERARY PRACTICES IN THE SAMARKAND OASIS: CHALLENGES AND NEW METHODS IN THE STUDY OF KURGANS FROM THE SAMARKAND OASIS, UZBEKISTAN

Facciani, Sara (Sapienza Università di Roma, Dipartimento di Scienze dell'Antichità; Alma Mater Studiorum Università di Bologna, Dipartimento di Beni Culturali) - Orrù, Valentina (Alma Mater Studiorum Università di Bologna, Dipartimento di Storia Culture e Civiltà) - Serrone, Eleonora (Alma Mater Studiorum Università di Bologna, Dipartimento di Storia Culture e Civiltà) - Suyunov, Samaretdin (Agency for Cultural Heritage, Samarkand Institute of Archaeology) - Bortolini, Eugenio (Alma Mater Studiorum Università di Bologna, Dipartimento di Beni Culturali) - Benazzi, Stefano (Alma Mater Studiorum Università di Bologna, Dipartimento di Beni Culturali) - Mantellini, Simone (Alma Mater Studiorum Università di Bologna, Dipartimento di Storia Culture e Civiltà)

The intensive investigation conducted by the Uzbek-Italian Archaeological Project in Samarkand, Uzbekistan, has revealed a high density of groups of mounded burials (kurgans) along the Karatyube foothills. On the contrary, the number of tepa (artificial mounds), usually associated with permanent settlement, are limited and their little number cannot justify such a large presence of burials. It is therefore arguable that the choice of the foothills as a burial place was not a prerogative of the communities who lived in this area, but also of the agricultural villages located in the lower irrigated plain, where settlements abound while the necropolises are few or absent. Moreover, the absence of archaeological record between the piedmont villages and the kurgan necropolis suggests this area was exploited for grazing. Although the development of rural villages partially changed the funerary practices in this area, as well the stones of the ancient kurgans reused for building purposes, many modern graves recall the small ancient ones.

Kurgans vary in location, size, orientation, and number of burials, and the lack or limited artefacts on the surface rarely makes it possible their dating. Thanks to an approach combining new stratigraphic excavations, high-resolution mapping, and ethnographic research, this paper aims to shed light on these issues.

7 SIX FEET UNDER IN THE STEPPE: SPATIAL RELATION OF THE SETTLEMENTS AND BURIAL GROUNDS IN PROTOHISTORIC SOUTH CENTRAL ASIA

Stanco, Ladislav (Filozofická fakulta, Univerzita Karlova)

The problem of burial sites and their spatial relationships to settlements in the protohistoric periods (the so-called Hellenistic, Transitional and Kushan periods) has been addressed to various degrees and with differing results in different parts of South Central Asia. While in southern Tajikistan large necropolises have been archaeologically investigated, especially in the Bishkent Valley, but for which it is not easy to find the corresponding settlements, in southern Uzbekistan the necropolises investigated so far are considerably smaller in number of graves, but usually have a clear spatial link to specific ancient settlements. The aim of this paper is to evaluate and attempt to generalize the spatial links between settlements and burial sites of the given period, while trying again to answer the question of whether a particular type of burial site can be clearly assigned to a specific type of landscape, and hence to a nomadic or settled community population. To answer this question, data from new excavations in recent years will be used, especially the Czech-Uzbek excavations at the site of Iskandar Tepa in the Sherabad district (southern Uzbekistan), but of course also data from older excavations in that area.

8 FROM SETTLEMENT TO BURIAL GROUND: TRANSFORMATION OF A MEDIEVAL SITE IN NORTHERN TOKHARISTAN

Damašek, Ladislav (Charles University)

From 2019 to 2022 several settlement sites dated to the Medieval period were excavated by the Czech-Uzbek expedition in the Kugitang and Baysantau piedmonts (Southern Uzbekistan, Surxondaryo Province, Sherobod and Baysun districts). At two of these sites, Lungi Tepa and Sabir Archa, a widespread phenomenon related to their changing function was encountered. Both settlements were used as a burial grounds after the abandonment of the settlement. This phenomenon was observed on many sites in the Surxondaryo Province alone and until today a lot of archeological

sites are used as burial grounds by contemporary village communities (e. g. Kurgan Tepa in Karabag or Mazarat Tepa in Kofrun). The burial grounds tend to be located atop of tell settlements. Both studied sites are tell settlements and were inhabited during the Early and High Medieval periods (5th–13th century CE). In the Late Medieval period, though, both were extensively used as burial grounds. In case of Lungi tepa, graves are dated by radiocarbon method to 15th–17th century CE. Graves at Sabir Archa can be attributed to same period based on analogies. However, later origin (18th–20th century CE) cannot be excluded by now. We may hypothesize about a possible pattern in this secondary burial use of these Medieval settlement sites in the oases of the Kugitang and Baysantau piedmonts. Moreover, this obvious change in sites function within the oases seems to be happening only after the Mongol invasion in 13th century CE. Previously settled sites were abandoned and later they were reused as places for burying the dead by the communities living at new locations in the neighbourhood. Thus origins of this custom that persists to this day can be traced at least to Late Medieval period. The reason for the usage of the earlier settlements as burial grounds is yet unknown.

1128 ROUNDTABLE OF THE COMMUNITY FOR TEACHING AND TRAINING OF ARCHAEOLOGISTS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Geary, Kate (Chartered Institute for Archaeologists) - Karl, Raimund (Universität Wien) - Scheyhing, Nicola (Independent Researcher; Kulturbetriebe Burgenlandkreis GmbH/Arche Nebra) - Preda, Bianca (Department of Cultures, University of Helsinki) - de Raad, Jesper (Independent Archaeologist)

Session format: Round table (without formal abstracts)

The skills we need as archaeologists have always been varied and the skillset seems to be constantly evolving. From digging to data, scientific techniques to storytelling, project management to professional ethics, how can we help archaeologists, their teachers and their employers keep knowledge and skills up to date when skills needs are expanding faster than ever before and the potential of new techniques and technology keeps increasing what is possible? This session will explore how universities, training providers, employers and professional organisations are rising to the skills challenges of advancing technology and techniques, AI and big data, widening access and diversity and the delivery of value to society amongst many other things. Are teaching and training methodologies innovating or struggling to keep up? How can they harness new technologies themselves? In a world that is rapidly changing and a sector that is often under-resourced, how are we bridging the gaps? This session, jointly organized by the Early Career Archaeologists (ECA) Community of the EAA, will also address questions early-career archaeologists may have regarding career paths, both inside and beyond academia. It will also touch upon issues of 'professionalisation' and what it means to be a professional archaeologist in the 2020s.

1129 INCLUSIVE ARCHAEOLOGY: PRACTICAL APPROACHES TO HERITAGE PARTICIPATION

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Spangen, Marte (Museum of Cultural History, University of Oslo) - Ratier, Pascal (French national institute for preventive archaeological research) - Falcone, Annalisa (Central Institute for Archaeology - Ministry of Culture, Italy)

Session format: Regular session

Preservation, dissemination and understanding of archaeological heritage among non-professionals represents both opportunities and challenges across Europe. The theme of opening the discipline to non-expert audiences has consequently become a priority within cultural policies of European countries. This session will explore how an inclusive archaeology can shape our professional practices to enhance our constructive contributions to society.

This session builds on pan-European initiatives like the Medieval Europe Research Community Manifesto (<https://mercmanifesto.org/merc-manifesto/>) and European Archaeology Days (<https://journees-archeologie.eu/>) which are intended to enhance awareness and engagement with archaeology and heritage across Europe.

We aim to explore why we wish for an inclusive archaeology as well as how we can deliver it. We welcome critical discussion of practical examples of projects that have led to an improved level of inclusivity, knowledge exchange, and the use of archaeological endeavours to promote social change. Specifically, we would seek to address these questions:

- How can a diverse and socially engaged archaeology contribute to improving well-being and a sense of belonging?
- How to attract new audiences who are not used to visiting archaeology sites?
- How to promote knowledge exchange between archaeology professionals and European citizens?
- How can we involve local residents in archaeological digs in their neighbourhoods?

- What can we do to raise public awareness of archaeological looting?
- How can we make European citizens aware of the entire archaeological process from the production of knowledge and to the management of heritage resources?

ABSTRACTS

1 EUROPEAN ARCHAEOLOGY DAYS: SHARING ARCHAEOLOGICAL HERITAGE

Ratier, Pascal (INRAP - National Institute for Preventive Archaeological Research)

In 2023, the EADs had their fifth edition with great success. More than 30 European countries participated in the event on the third weekend of June. Despite the health crisis, the EADs have continued to grow, attracting more public support, new countries and new organisers with each edition. How can the EADs develop by making an event a place where the public can meet the entire archaeological chain of operations? The event can only find its audience through the intersection of national communication, driven by a national and public actor, and communication developed by the local organisers to their usual networks. Another of the fundamental missions at national level is to mobilise all the archaeological actors in the country, "from the excavation to the museum", so that the public can have access to the diversity of the entire archaeological process. It is therefore essential that the national authorities managing archaeology in each European country be able to coordinate the event on their territory, in order to integrate it into their overall policy of sharing the archaeological heritage. The creation of a network of coordinated organisers at national level in each country is therefore an essential challenge.

A major topic for discussion will concern the ways these EADs can contribute to the development of a common identity, while also preserving the cultural diversities that characterise a plural Europe.

- What audience(s) and communication policies are best suited for EADs?
- How can these EADs be used to acquaint European citizens with the entire archaeological process concerning both the production of knowledge and the management of the past?
- How can we make these days a genuinely European event in spite of the diversity of archaeology practices and policies across the countries of Europe?

2 ARCHAEOLOGY DAYS NETHERLANDS, ENGAGING AND CONNECTING A YOUNGER AUDIENCE BY BUILDING UP & INSPIRING A NETWORK OF 250 PARTNERS

Berkelbach, Janneke (Nationale Archeologiedagen)

The 'National Archaeology Days' in the Netherlands have been organizing annual events for the past 8 years. The primary goal is to enhance public engagement with archaeology throughout the country. We are dedicated to making Dutch archaeology accessible and interesting for a diverse, inclusive audience.

The Archaeology Days span three days each year, providing the general public with the opportunity to explore the fascinating and enjoyable aspects of archaeology. These days bring the past to life, offering a unique chance for people to witness what lies hidden in the Dutch soil.

All entities involved in Dutch archaeology, including museums and volunteer organizations, are encouraged to open their doors and guide the public into the captivating world of archaeology. Activities range from pottery determination workshops, participation in real excavations, and archaeological hiking trips to plays and lectures.

The presentation will reflect on how we have established a network of over 250 organizations in the Netherlands to develop and organize these events.

Particularly noteworthy is our inclusive approach to engaging a younger audience. Through our network of young archaeologists, the Young Underground Professionals (YUPs), our think tank of young professionals, and the resulting ArchaeoNight organized and programmed by the YUPs; the recently formed young archaeologists' club; our platform "Archaeology Lives!" and the Grand Archaeology Show. Our emphasis is on embracing the diverse and inclusive audience of tomorrow.

Examples of inspiring public activities involving archaeology, often realized in close cooperation with other cultural disciplines such as fashion, technology, arts & crafts, and design, will be presented.

3 EXPERIENCES OF POPULARISATION OF ARCHAEOLOGY IN THE FRAMEWORK OF THE EADS: THE CONTRIBUTION OF THE CENTRAL INSTITUTE FOR ARCHAEOLOGY (ICA)

Falcone, Annalisa (Istituto Centrale per l'Archeologia)

The world of archaeology exerts two contrasting reactions in the collective imagination: love for the discipline ("as a child I wanted to be an archaeologist") or total disinterest ("enough with these shards and stones!"). The objection that

is often raised by this disinterested public is that “archaeologists only talk to archaeologists”, as if the archaeological discipline, in itself, is closed to the non-expert public. That’s why, The Central Institute for archaeology (ICA), part of the Italian Ministry of Culture, fulfilling its mission of promoting archeology in its broadest sense, also at an international level, has enthusiastically joined the initiative of the European Archeology Days (EADs), promoted by INRAP since 2019 on a European scale. At each edition, the ICA has offered the opportunity to delve into topics related to the diffusion of the discipline to a non-expert audience, involving scholars in addressing topics of interest to the general public or reflecting on the communication strategies of the archaeologist’s actions.

This contribution will focus especially on the experience achieved in collaboration with the Special Superintendency of Rome for the 2024 edition of the EADs.

4 NATIONAL ARCHAEOLOGICAL INSTITUTE WITH MUSEUM AT THE BULGARIAN ACADEMY OF SCIENCES. SOCIALIZATION OF ARCHAEOLOGICAL HERITAGE: CURRENT METHODS AND PERSPECTIVES.

Pramatarov, Kaloyan (National Archaeological Institute with Museum at Bulgarian Academy of Sciences)

The National Archaeological Institute with Museum at the Bulgarian Academy of Sciences is a national center for comprehensive research, promoting and socialization of the material and the spiritual culture of the tribes and the people that have inhabited the present-day Bulgarian lands from remote prehistory to the 18th century AD. As a social and educational space, the National Archaeological Museum has elaborated a series of dynamic analogous and digital methods for working with the broad public. The present report describes the models for the development of educational programs and active socialization of the cultural-historical heritage, applied within the context of pan-European initiatives such as the European Archaeology Days, The European Night of Museums, and European Researchers Night. The participation in them has been predetermined by the desire to establish a persistent professional network for mutual aid and to apprehend foreign museum concepts and methods. By describing the problems and perspectives in front of Bulgarian Museology, the report seeks to provoke international discussion and exchange of experience.

5 NEW TECHNOLOGIES TO ENHANCE HERITAGE PARTICIPATION. EXPLORING AND COMMUNICATING ARTISANAL PRACTICES AT THE ARCHAEOLOGICAL PARK OF URBISAGLIA

Xavier de Silva, Ludovica (University of Macerata) - Cingolani, Sofia (Direzione Regionale Musei Marche)

Communicating the cultural heritage, making it accessible, and generating audience engagement are among the objectives that the Regional Directorate of Museums in Marche envisages for its museums and archaeological sites. These goals, as well as sharing knowledge concerning the results of recent digs in archaeological parks, can be challenging but, at the same time, essential to promote the park as a dynamic place where ongoing research can always add new elements to the understanding of the past and communities can learn about local cultural heritage and strengthen their sense of belonging to the territory.

The work recently carried out within the European Adrion TRANSFER Project and led by the University of Macerata focused on the application of new technologies to the enhancement of cultural heritage and resulted in the development of a Virtual Reality (VR) experience about the Republican kilns of Pollentia-Urbs Salvia and their environment. The project has been carried out with the constant involvement and participation of the Park in order to take into account the effectiveness of the technology in terms of usability and accessibility as well as its best integration with the existing dynamics of the site.

With this contribution, we would like to share how the involvement of different actors and professionals has improved the local awareness and commitment towards the Park’s activities and its potential as a centre capable of driving cultural development. We would also like to share the first phases of implementation of the VR experience in the Park and its use outside the archaeological site in order to explore the possibilities that Information and Communication Technologies (ICTs) can provide in view of promoting knowledge exchange between archaeology professionals and citizens, raising awareness about archaeological heritage in local communities, and spreading knowledge among young people through the involvement of education institutions.

6 THE UNEXPLOITED POTENTIAL OF GRAPHIC NARRATIVES IN ARCHAEOLOGY

Gerberg Høstrup, Sebastian (Aarhus University) - Foresi, Federica (Museum Vestsjælland)

This paper focuses on making archaeology attractive to the public as well as the reluctance towards using comics for scientific and historical dissemination, since they are often associated with a low cultural value. We have difficulty thinking of comics as a suitable academic tool and this is especially evident in scientific publications.

The attempt to express meaning through images is inherent in human nature and can be traced from the earliest known cave paintings more than 40,000 years ago to IKEA assembly instructions. Despite permeating every sphere of modern society, the diverse toolbox of visual language is still largely being ignored by archaeology.

The use of comics for communicating archaeological knowledge and scientific interpretation is not new but it is far from common practice. We will showcase varied uses of comics with examples from France, Italy, the UK and Denmark.

The impact that graphic novels based on historical events can have on the public is already clear with publications such as Maus (1980-1991), Footnotes in Gaza (2009), Kobane Calling (2015-2020) and Sapiens (2020-2021). They address phases of our history, ranging from contemporary events to the beginning of human prehistory. If we make this form of public engagement a common practice for projects instead of remarkable single cases, we will build a stronger relation between the public and its interest in archaeology to generate an increased social value to our research.

In addition to incorporating the visual language of comics in academia, this paper also suggests comics as a way of “merchandising” archaeology, by making complex ideas and convoluted topics more accessible to a wider part of the population. An integral part of achieving this will be to balance the negotiation between scientific knowledge and creative storytelling so as to produce a product which possesses the strengths of both.

7 HISTORYTELLING: ENGAGING PEOPLE AND TELLING THE HISTORY OF YESTERDAY USING TODAY’S MEDIA

D’Eredità, Astrid (Italian Ministry of Culture)

Since digital and social media became established as customary tools of communication in archaeology, after an initial diffident approach on the part of institutions, there has been a progressive rapid evolution in the syntax and semantics of their use. In parallel, the growing need to quickly adapt to the new communication standards has been a driving force for the development of hybrid professional figures who are both experts in algorithms and in iconography and stratigraphy.

Videos, web series, reels, podcasts, memes, wikipedia entries are today the main means of disseminating historical archaeological stories and information; irony and extemporaneity (real or constructed in post production) are among the most frequently used storytelling keys to bring already known archaeological contexts and new discoveries to the general public.

At the end of an excursus on the most interesting case studies from the Italian scenario, this contribution focuses in particular on the experience gained in the digital communication projects of the Colosseum Archaeological Park and on the main topics and tools used for online and offline audience engagement.

8 ARCHAEOLOGICAL EXHIBITIONS IN THE MUSEUMS OF MONTENEGRO TODAY: THE STRENGTH OF TRADITION AND THE ABSENCE OF INNOVATION

Medin, Dušan (Faculty of Culture and Tourism University of Donja Gorica)

In this work, the author deals with the presentation of the current situation of archaeology in Montenegro, with a focus on public cultural institutions that own archaeological collections (public museums and galleries). The discussion examines problematic aspects of existing settings, including methods of installation, traditional approaches, the continued display of old and outdated exhibitions, inadequate labelling, bland displays of objects, the lack of adequate internet presentations. The discussion will also explore the social networks of museum institutions and their elitist approach, as reflected in inadequate communication with the community and a non-participative approach to their collections. The museums of Montenegro today do not meet current expectations about social inclusivity, nor do they conform to the concept of definition of museums as defined by ICOM, with the Convention on the Value of Cultural Heritage for Society (Faro Convention). In recent years a few archaeological exhibitions in Montenegro have been modernized, using new technology and adopting an innovative, inclusive and participatory approach. The success of these new displays will also be examined in the presentation.

9 ENHANCING INCLUSION IN THE HUNGARIAN NATIONAL MUSEUM

Pásztor, Eszter (Hungarian National Museum National Institute of Archaeology) - Bedő, Valér (Hungarian National Museum National Institute of Archaeology)

National Institute of Archaeology (NIA), a member institution of the Hungarian National Museum (HNM), launched an independent initiative to boost involvement of persons with disabilities in the dissemination of knowledge. Our aim is not only to improve access to culture and science, but also to create the opportunity to make reception easier to enhance the experience. Therefore, we invited Péter Straub, a blind archaeologist who produces audio narrations (a mode of audiovisual translation providing access to audiovisual texts to viewers excluded from the visual codes) to show

archaeological artefacts, to lead guided tours of the exhibition and to take part in working out the methods. Straub led a special tour for blind and visually impaired people to share his experiences, where they had the opportunity to sense and touch copies of artefacts, thus gaining peculiar experience. Special tour for the deaf and hard-of-hearing visitors are held as regular ones in the exhibition, during which sign language interpreters support the tour leader.

By integrating synergies deriving from the representatives of concerned organisations, we aim to develop a secure ambience for disabled people, where they can encounter beauties of our profession. Besides adopting good practices, we consider it important to show that our inclusive methods are considered when preparing exhibitions.

We are aiming to synthesise our experience of working with the special needs community, particularly in the early phases of planning exhibitions. For this to be a success we will also need to hold sensitisation trainings for those employees who directly work with visitors.

10 **ARCHAEOLOGY AND HERITAGE IN SCHOOL - NEW APPROACHES FOR AN INCLUSIVE ARCHAEOLOGY**

Synnestvedt, Anita (University of Gothenburg/Department of Historical studies)

Crucial questions within the field of public archaeology are how to reach new audiences not used to different perspectives of archaeology. If we want to develop the field of public archaeology and build an inclusive archeology for the future, the first step is to start with the children. I therefore considered it important to write a book addressing teachers and teacher students about teaching and learning archaeology and heritage (Archeology and Heritage in schools, 2024). These target groups often have quite limited (as well as rather old) knowledge about archeology and heritage, and on the other hand, their task is to teach new generations about these subjects. Consequently, questions discussed are what heritage and archaeology means and how it can be used in schools in order to enrich several subjects within the curriculum except history. Another important aspect is to problematize and highlight how archaeology and heritage are part of contemporary society. Within primary and secondary schools archaeology is mainly considered a subject related to prehistory. My aim is to change these perspectives. I will present some examples to you of how this can be implemented in practice. The examples discuss how teachers and pupils can conduct small archaeological excavations by their own, how to conduct the exercise called “the heritage bag” which means filling a bag of your own heritage and how to make sense of place and belonging.

11 **BUILDING AN COMMUNITY AT THE ARCHAEOLOGICAL INSTITUTE OF AMERICA THAT WELCOMES NON-PROFESSIONALS**

Langlitz, Meredith (Archaeological Institute of America)

This paper seeks to demonstrate the advantages of serving both professional and public audiences and explore how this affects program delivery for an archaeological organization.

Founded in 1879, the Archaeological Institute of America (AIA) is North America’s oldest and largest archaeological organization. The Institute has a dual mission to serve both professional archaeologists as well as the public. For 75 years the AIA has published ARCHAEOLOGY magazine, a popular general interest publication sent to approximately 200,000 subscribers every other month that fosters an appreciation of archaeology among the largest portion of our base. The AIA also provides additional opportunities for community building and greater public involvement in archaeology. This includes a smaller subset of supporting members grouped into over one hundred local Societies throughout North America that offer community programming and Institute sponsored outreach programming such as International Archaeology Day, the AIA National Lecture Program, and an online ArchaeoCon event.

The results are an intentional community dedicated to archaeology that provides support for the Institute’s mission, archaeological research, and advocacy efforts to protect cultural heritage. This paper will discuss the synergies of the AIA’s “Excavate, Educate, Advocate” mission with a focus on public programs such as the AIA National Lecture Program and International Archaeology Day; how the AIA connects its audiences in support of archaeological research; and rallying stakeholders during advocacy campaigns to secure international agreements to protect cultural property.

12 **THE ART OF WELL-BEING, WITH ART, ARCHAEOLOGY AND LANDSCAPE**

Boldrighini, Francesca (MiC - Parco archeologico del Colosseo) - Costa, Silvio (Mic- Parco archeologico del Colosseo) - D’Offizi, Silvia (Mic - Parco archeologico del Colosseo) - Ferrari, Elena (Mic- Parco archeologico del Colosseo) - Schiappelli, Andrea (Mic- Parco archeologico del Colosseo) - Lamonaca, Federica (Freelancer archaeologist) - Ioppi, Francesca (Mic- Parco archeologico del Colosseo)

Visiting cultural sites is good for everyone. No doubt. But certain categories of visitors can gain particular benefits from the observation of works of art and from the participation in activities performed in contexts where archaeology and landscape blend

admirably, revealing the fascination of the ancient world and triggering intellectual inputs. This is not a recent discovery, but combined benefits of art and landscape for wellbeing, have recently gathered greater recognition in Italy and abroad, not least under the banner of Care, Culture and Beauty. This wider recognition is thanks to the efforts of MiC (Ministero della Cultura), institutions, medical doctors and Third Sector associations.

This paper will focus on the Salus per Artem and PArco Green programmes, at the Parco Archeologico del Colosseo. Since its foundation PArCo is convinced that art, in all its forms, including dance, theatre, and music, contributes to well-being. Beauty provokes emotions capable of acting on the mind better than medicines, as many neurologists have affirmed within scientific studies.

Studies into the health benefits of cultural activities have grown exponentially in recent years and have been recognised by WHO under the term Cultural Welfare in their Health Evidence Network Synthesis Report 67, the largest review on the subject. The lexicon of the sector has also been enriched: we speak now of ‘exposure to cultural heritage’ as a source of wellbeing.

We can now speak of a reciprocity between the two spheres: producing health through culture and supporting culture through health.

Also with regard to the conservation and enhancement of landscape in all its forms, PArCo has initiated many different activities with the common aim of reducing environmental impact, decreasing pollution, preserving the ecosystem and enhancing biodiversity. In short, activities to promote a way of life which is ‘in tune’ with our natural environment.

13 **EMPOWERING COMMUNITIES THROUGH ARCHAEOLOGY: THE TERRA LEVIS APPROACH IN ÁVILA, SPAIN**

López García, Juan Pablo (MASAV; Terra Levis. Arqueología en Comunidad)

“Terra Levis, Arqueología en Comunidad” -Ávila, Spain, emerges as a pioneering initiative in community archaeology, embracing the principles of collaboration, participation, and empowerment in archaeological research. Our proposal focuses on breaking away from the traditional paradigm of archaeology, where experts dominate decision-making and the local community plays a passive role.

At Terra Levis, we adopt an inclusive approach that actively involves the community in all stages of the archaeological process. From identifying potential sites to interpreting findings, we work hand in hand with local residents, recognizing and valuing their traditional knowledge and emotional connection to cultural heritage.

Our methodology is based on training and empowering community members in archaeological techniques, thus fostering a sense of ownership and shared responsibility towards their environment’s past. Additionally, we promote the creation of dialogue and reflection spaces where academic and local knowledge intertwine, mutually enriching the understanding of the past.

The outcomes of our project go beyond mere archaeological research, contributing to the social and cultural development of local communities. By empowering residents to become active guardians of their heritage, we foster a sense of identity and belonging that transcends temporal boundaries.

In our presentation, we will share the experiences, challenges, and achievements of Terra Levis, highlighting the transformative potential of community archaeology to build bridges between the past and present, academia and society, and individuals and their heritage.

14 **CITIZEN SCIENCE AT THE NATIONAL TRUST UK- INCLUSIVE ARCHAEOLOGY FOR EVER FOR EVERYONE?**

Caroli, Viviana (The National Trust) - Young, Janine (The National Trust)

Working with volunteers is well established in British and International Archaeology, with significant benefits for participants and very real public benefit flowing from such experiences. Traditionally the focus on volunteer participation has been in supporting archaeological excavation, but with increasing complexity and costs associated with such activity, the enhanced access to advanced technologies and the increased need to find solutions for nature and climate, it is imperative to think about how we can broaden the opportunities we offer to support our understanding of the archaeological resource and how we care for it in a world experiencing significant and rapid change. The National Trust looks after in excess of 98,000 recorded heritage assets – from Bronze Age burial mounds and Medieval monastic ruins to Iron Age hill forts and Second World War pillboxes. It is fundamental that we understand the condition of our sites in order to effectively manage them and to do so we deliver a programme of condition monitoring through the provision of training and resources to volunteers, working closely with property teams.

This paper will introduce and share the benefits derived from the National Trust HART (Heritage and Archaeology Rangers Team) monitoring programme. It aims to present the impact that public participation has brought to our heritage capital and resources by regularly monitoring archaeological sites and contributing to their effective management, while highlighting the wellbeing and public benefits derived from engaging with the historic environment.

By setting the framework of a replicable process we are hoping to aid other international organisations and bodies to deploy a model which can significantly contribute to direct conservation activity, prioritise conservation work, monitor for the impacts of environmental change and plan for land use change for the benefits of present and future generations.

15 THE COMMUNITY ARCHAEOLOGY PROGRAMME NORTHERN IRELAND (CAPNI)

Donnelly, Colm (Queen's University Belfast) - Murphy, Eileen (Queen's University Belfast)

The paper will provide an overview of the Community Archaeology Programme Northern Ireland (CAPNI) which was launched in February 2024. CAPNI is a structured programme of community archaeology to be undertaken across Northern Ireland over the three-year period from 2024 to 2026. Supported by the National Lottery Heritage Fund and based within Queen's University Belfast, the programme will enable CAPNI's archaeologists to facilitate and support local communities to examine their past through direct participation in co-designed activities, including excavation, survey, experimental archaeology and walking tours. The programme will also include regional School Hub events where the CAPNI team to introduce children to the work of archaeologists, archaeological sites in their locality and the importance of our archaeological heritage. CAPNI has its origins in the work conducted by the Centre for Community Archaeology since 2017 and will call upon the established relationships that the unit has with a wide range of partner organisations – community groups, local councils, and historical societies – across Northern Ireland. Hosted within a post-conflict society with significant well-being issues, CAPNI will also work with groups within the local health sector – such as Macmillan Cancer Support and AwareNI – to develop community archaeology as a means to improve quality of life through participation.

16 AN EXPERIENCE OF COLLABORATIVE ACTION BETWEEN RESEARCHERS, EDUCATIONAL CENTRES AND SOCIAL ACTORS: CONCIENCIA HISTÓRICA PROJECT

Fernández Mier, Margarita (University of Oviedo) - Sánchez-Broch, Paloma (University of Oviedo)

We present the experience of the project ConCiencia Histórica. Archaeology as a tool for scientific dissemination in rural areas, an educational proposal of the research group LLABOR (University of Oviedo) to stimulate citizen participation in science and technology through archaeology and heritage. It is aimed at children and young people in rural areas of Asturias (Spain) that seeks to promote greater knowledge of the territory in which students live, discover the heritage values of their environment and encourage the creation of identity elements that prevent migration to the urban world.

The aim of this educational proposal is to connect the scientific research carried out by the LLABOR group with the local communities in the territories where it is carried out, promoting the exchange of knowledge. The rural environment is currently facing a series of problems - depopulation and ageing of its inhabitants, crisis of production models, etc. - which urgently require the involvement of scientific agents. Training and dissemination actions are needed to balance the opportunities of rural and urban inhabitants. Among other objectives, the aim is to stimulate scientific vocations, generate interest in archaeology and heritage, and contribute from the scientific sphere to the analysis and management of current problems.

ConCiencia Histórica began in 2014 in the municipality of Belmonte de Miranda, growing and extending to other municipalities such as Grau/Grado. It is currently working with four schools and more than 200 kindergarten and primary school students. The project is funded by the Spanish Foundation for Science and Technology (FECYT) (where it has been recognised in 2018 as one of the most innovative initiatives of this call), as well as by local administrations which actively participate and collaborate.

17 A ROAD TO CONNECTION: CREATING A CROSS-BORDER NARRATIVE THROUGH COMMUNITY ARCHAEOLOGY IN THE WESTERN PYRENEES

Edeso Egia, Mikel (Aranzadi Science Society) - Mendizabal-Sandonís, Oihane (University of the Basque Country (UPV/EHU); Aranzadi Science Society) - Aiestaran, Mattin (University of the Basque Country (UPV/EHU); Aranzadi Science Society) - Narbarte, Josu (University of the Basque Country (UPV/EHU); Aranzadi Science Society) - Ruiz-González, Daniel (Aranzadi Science Society) - Conde-Egia, Eider (Aranzadi Science Society) - Agirre-Mauleon, Juantxo (Aranzadi Science Society)

Over the last decade, a group of archaeologists have located the Iler XXXIV Pyrenean Roman road and several Roman-period sites linked to it, such as the Zaldua settlement (Auritz/Burguete), Donazaharre (Saint-Jean-Le-Vieux) or Artzi (Valley of Artzi).

Little archaeological study of this rural and mountainous territory has been carried out until now. Nevertheless, since 2022, archaeologists from Aranzadi Science Society have developed a research and dissemination project that aims to connect both sides of the Pyrenees (Spanish and French) by researching the road that crossed this area, linking Roman sites in both countries under a community-based archaeology model.

For that purpose, a common plan is proposed where excavations feature local population and archaeology students that partake on the research and management of the sites. Besides, the project seeks to foster collaboration and mutual knowledge between Pyrenean municipalities with Roman sites, creating common resources and promoting joint dissemination activities. The ultimate goal of the project, supported by the Eurorregion Nouvelle Aquitaine-Euskadi-Navarra programme, is to involve local communities in the valorisation of their heritage, create new cultural resources to attract visitors and build bridges between rural municipalities that face common demographic challenges across borders.

18 PARTICIPANT OBSERVATION AS A MODEL FOR COLLABORATIVE ARCHAEOLOGY: INSIGHTS FROM INISHBOFIN ISLAND, IRELAND

Lash, Ryan (University of Notre Dame) - Burke, Tommy (Inishbofin Island Archaeological Walking Tours)

Participant observation is the principal, if not defining methodology of social anthropology. It is a method premised on living attentively with others, observing while participating in the practices of the people among whom one seeks to learn. This paper will explore how participant observation can provide a model for collaborative archaeology and public heritage projects, in which both archaeologists and community members act as participant observers.

Since 2007 the Cultural Landscapes of the Irish Coast (CLIC) Project has undertaken community-based archaeological and ethnographic research on the west coast of Ireland, particularly on Inishbofin, a small island of 184 residents with a bustling summer tourist market. Collaborative work here has included public presentations of research, artefact show-and-tells, open excavations for primary school students, co-produced publications and presentations, experimental archaeology demonstrations, and ethnographic participant observation focused on contemporary engagements with local heritage.

We argue that some of the most productive activities – in terms of both public impact and academic insight – have emerged from the reciprocal exchange of experience and expertise between academics and local people. In this paper, the co-authors will discuss their respective experiences of collaboration as participant observation: Lash's participation in contemporary farming and ritual practices and Burke's participation in archaeological excavation, analysis, and dissemination. These experiences have generated greater mutual understanding of the processes of knowledge production in the domains of both local oral history and archaeological research. The result has been greater public impact through collaborative outputs in a variety of media (i.e. tourist guide book, heritage festivals, podcast) and an enhanced capacity to synthesise new archaeological data with local traditional knowledge.

1132 FROM CHAOS TO COHERENCE. THE SCIENTIFIC VALUE AND PERSPECTIVE ON COMMINGLED AND FRAGMENTARY HUMAN REMAINS

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: László-Mateovics, Orsolya (ARDIG-Archaeological Service GesmbH) - Seppänen, Liisa (University of Turku; University of Helsinki) - Dec, Olga (Adam Mickiewicz University | UAM · Faculty of Archaeology Master of Arts)

Session format: Regular session

Human skeletons provide valuable insights into the lives of individuals, including their life quality, activities, and various biosocial factors they may have experienced. On a larger scale, they can help understand mortuary patterns, population dynamics, and the distribution of diseases. However, if human remains are comingled and fragmentary,

they can create significant challenges both for archaeologists and anthropologists. Human remains can form into such conditions due to various processes, including secondary burials, post-depositional processes such as human interactions and diagenesis which can disturb the original contexts of interments. In the past, graves may have also been disturbed by robbery, while modern agricultural or construction activities can also lead to disturbances. All of these can lead to an accumulation of partially or completely decomposed disarticulated elements. Contrary to these, it is still possible to gain important insights into past behaviors by assessing the taphonomic parameters and funerary behavior, and researchers can cross-reference anthropological data with spatial and stratigraphic information.

Our session aims to bring together researchers from the fields of archaeology, anthropology, and forensic anthropology to share their expertise on this special bioarchaeological source, with a focus on methodological solutions and ethical considerations.

Through case studies, we seek to evaluate possible methodological solutions that can help us fully explore the nature and processes that lead to the formation of these chaotic and complicated contexts. We aim to answer questions such as: How can we work with these remains? How much information can we obtain from them? Ultimately (in some cases), we need to reason why their preservation and maintenance is important not only from scientific, but also from ethical perspectives. Hence, these remains can have different scientific values and therefore deserve our attention.

ABSTRACTS

1 HEANING WOOD: THE IMPORTANCE OF INTERDISCIPLINARY APPROACHES IN UNDERSTANDING FRAGMENTED, MULTI-PHASE CAVE BURIALS IN NORTH WEST ENGLAND

Warburton, Keziah (University of Central Lancashire) - Peterson, Richard (University of Central Lancashire)

Caves have long been recognised as an important aspect of Neolithic burial practice and our understanding around such practices has been supported by taphonomic analysis and re-analysis of original excavations. These environments, however, often lead to fragmentation, commingling, and destruction and historically smaller parts may have been ignored.

Heaning Wood was selected as one site for analysis and offers an excellent example of the depth of information available from fragmented assemblages. An MNI of nine was established from an assemblage initially commingled with large amounts of faunal material. A Geographic Information System (QGIS) was used as a tool for exploring taphonomy at multiscale levels. Through the understanding of taphonomic patterns at a fragment, element, body and stratigraphic level, burial narratives and sequences were reconstructed.

Subsequent radiocarbon dating and aDNA highlighted the significance of these burials, with one individual dating to the Early Mesolithic, currently the oldest date for human burial in the North of England. Dating shows successive use of the cave between the Mesolithic and Early Bronze Age, with long hiatus between periods. Preliminary aDNA results have shown genetic sex for three individuals, and potential sex for another three. Two individuals, both dated to the Early Neolithic, show promise for deeper genetic sequencing.

Through a combination of osteological profiling, taphonomic and spatial analysis with GIS, and techniques such as radiocarbon dating and aDNA, we have garnered a detailed understanding of a complex cave assemblage. This shows the inherent value contained in fragmentary and commingled human remains.

2 RECORDING COMMINGLED ARCHAEOLOGICAL HUMAN SKELETAL REMAINS USING LIDAR: A CASE STUDY FROM LATE BRONZE AGE HALA SULTAN TEKKE, CYPRUS

Casa, Bianca (The Cyprus Institute) - Vassallo, Valentina (The Cyprus Institute) - Orabi, Rahaf (The Cyprus Institute) - Hermon, Sorin (The Cyprus Institute) - Fischer, Peter (University of Gothenburg)

Complex mortuary contexts, including disarticulated and commingled archaeological skeletal remains, can pose a great challenge for archaeologists to record and excavate. During excavations at Late Bronze Age Hala Sultan Tekke, Cyprus, a two-tiered approach was used for the detailed recording of disarticulated, commingled skeletal remains as part of an archaeothanatology approach. Firstly, individual bones were manually identified and assigned an identification label (i.e. bone letter) in situ by specialist human bioarchaeologists. Secondly, iPad Pro LiDAR and the application Polycam were used to stratigraphically document tomb mortuary contexts and archaeological human skeletal remains in situ. Manual recording enabled the assessment of possible articulations, funerary taphonomy, repeated cases of primary and secondary burial, and the differentiation of anthropogenic and environmental agents that acted upon the archaeological human skeletal remains. LiDAR facilitated the rapid 3D data capture of the mortuary context in minutes, capturing a combination of geometry and texture through a photogrammetric technique. This technique generated a mesh that was able to be combined, scaled and layered into a single 3D model. The resulting 3D models of mortuary context are of high resolution and display fine details including bone articulations and positioning, with an error margin of less than 1cm accuracy. The 3D models may be used for virtual taphonomy and the assessment of

site formation processes. The models may be viewed layer by layer and from all axes, and can be metrically measured. In the case of Hala Sultan Tekke (and Cyprus in general) where archaeological skeletal remains are of poor preservation and fragmentary nature, this two-tiered approach using manual recording in combination with the creation of 3D models enabled the detailed recording of disarticulated and commingled archaeological skeletal remains in situ, whilst simultaneously creating a digital stratigraphic record of the archaeological deposits that can be preserved and restudied.

3 OSTEOLICAL CHAOS - AN INTEGRATIVE METHODOLOGICAL APPROACH TO THE STUDY OF HUMAN REMAINS FROM THE MAS ROUGE COLLECTIVE BURIAL (FRANCE)

Monier, Emma (LAMPEA UMR 7269, CNRS, Aix-Marseille Université, Ministère de la Culture) - Donat, Richard (INRAP Midi-Pyrénées, CAGT UMR 5288, CNRS)

The Mas Rouge collective burial, located near Montpellier, France (3200-3000 BC), initially served as a domestic cellar before transforming into a resting place for nearly 200 individuals, is a well representation of a site that could appear chaotic. The first deposit of corpses in connections, probably linked to a still unknown mortality accident, is followed in time by ossuary spaces of commingled bones, until a condemnation fire sealed the site, distinguishing it from other collective burials (Y. Tchérémissinoff, dir.). This unique grave, associated with its habitat, presents an intriguing feature with an equal representation of children and adults, a rarity in Neolithic contexts.

Our primary challenge, through a comprehensive anthropological inquiry, is to reconstruct the recruitment profiles and demographic dynamics of the Neolithic village population utilizing this grave. Despite encountering significant challenges due to the prevalence of fragmented and isolated bones at Mas Rouge, influenced by various taphonomic factors like human activities and post-depositional biases including fire, sediment compaction or chemical agents, we've embraced these hurdles as opportunities for innovative exploration. These conditions have inspired us to develop a systematic approach for studying human remains in this intricate context, thereby unravelling the complex of events and their spatiotemporal succession. Complementing our anthropological methods, we employed forensic and archaeozoological tools for the conservation study, including observation and coding systems for fractures and surface modifications (with an experimental repository), all integrated into GIS.

Preliminary findings from our stimulating investigation of one ossuary space reveal compelling insights, including the identification of two distinct fire alteration patterns, late fractures, and evidence of carnivore activity impacting select bones, likely belonging to a canid-like species.

In conclusion, our multidisciplinary taphonomic approach offers captivating insights into the operations and the history of collective burials, thereby enhancing our understanding of Neolithic populations.

4 UNRAVELLING THE MYSTERY. THE CASE OF THE PARTIALLY COMMINGLED 3RD MASS GRAVE FROM THE MOHÁCS MEMORIAL PARK (HUNGARY)

De Andrés Montero, Marcos (Department of Biological Anthropology, University of Szeged) - Kocsmár, Réka (Department of Biological Anthropology, University of Szeged) - Vig, Viktor (Department of Biological Anthropology, University of Szeged) - Molnár, Erika (Department of Biological Anthropology, University of Szeged) - Tihanyi, Balázs (Department of Biological Anthropology, University of Szeged; Department of Archaeogenetics, Institute of Hungarian Research) - Bereczki, Zsolt (Department of Biological Anthropology, University of Szeged) - Pálfi, György (Department of Biological Anthropology, University of Szeged)

In 1526 took place one of the most relevant, and yet unknown, battles in the history of Central and Eastern Europe. The Battle of Mohács, where the Hungarian army was defeated by the Ottoman imperial army is still regarded by Hungarian historiography as one of the most relevant moments in their history, and one that would have a great influence in the future of the Carpathian region. In order to gain more knowledge about that historical event, a mass grave containing the remains of approximately 300 individuals was excavated in the surroundings of the presumed battlefield between 2020 and 2022. Although originally thought to be a primary burial, the remains found inside the grave were partially disarticulated and commingled. For the purpose of solving the main bioarchaeological questions related to this burial (namely the role of the people buried in it and whether they were killed in action or executed in the aftermath of the battle), rearranging these disarticulated remains to the fullest extent is imperative. To achieve that aim, a set of tools and working protocols have been developed and adapted to be employed in this project. First, a geographical information system software was used to record the position of the different skeletal elements within the grave, including the distance between them. Various osteometric formulae were applied to narrow down the number of potential matches for each element. In addition, a new anatomical coding system proved useful to discriminate skeletons based on the level of completeness. A series of preliminary results obtained after using these tools are to be presented.

5 HIGHLY COMMINGLED BONE SERIES FROM ALCALAR (PORTUGAL): PAST FUNERARY GESTURES DURING THE 3RD TO THE 2ND MILLENNIUM B.C. CAL. TRANSITION

Neves, Maria João (Universidade de Coimbra; CIAS - Research Centre for Anthropology and Health - Life Sciences Department of the University of Coimbra; Institute of Interdisciplinary Research - University of Coimbra) - Ferreira, Maria (University of Coimbra; Laboratory of Forensic Anthropology, Centre of Funcional Ecology - Life Sciences Department of the University of Coimbra; CIAS - Research Centre for Anthropology and Health - Life Sciences Department of the University of Coimbra) - Silva, Ana (University of Coimbra; CIAS - Research Centre for Anthropology and Health - Life Sciences Department of the University of Coimbra; Centre of Funcional Ecology - Life Sciences Department of the University of Coimbra)

Late Prehistoric funerary sites have dynamic and complex biographies. These sites include many architectural solutions (passage graves, tholoi, hypogea, pits, etc.), housing fresh cadavers, skeletons, commingled bones, and various material culture items.

In the Portuguese classical archaeological region of Alcalar, the scientific exploitation of a considerable number of prehistoric funerary sites since the end of the 19th century, allowed the identification of an important set of highly commingled skeletal remains found in natural caves, artificial caves or hypogea, tholoi and dolmens, and even in pits.

The implementation of an archaeothanatological protocol coupled with GIS analysis and the obtention of radiocarbon dates from well-defined stratigraphic contexts provided a new understanding of the rhythm of funerary depositions, interruptions of use, reformulations, abandonment of the monuments, and how these assemblages were affected by taphonomic factors over the last millennia.

In this work, we will present the results of an archaeothanatological analysis of three sites, allowing the reconstruction of past funerary practices. The biological profile of the dead and the identification of bone changes compatible with pathological lesions were carried out with standard anthropological methods. The skeletal remains here were found in the Tholos of Alcalar 9 (Minimum Number of Individuals [NMI] = 6); the upper level of Monte Canelas Hypogeuum I (NMI = 24); and the Alcalar settlement (NMI = 2). Even though a small number of individuals were found, a large sample of highly fragmented and commingled bones has been recovered (> 1500 fragments), showing the contribution of highly commingled series to a better understanding of this Chalcolithic-Bronze Age transitional period. This work highlights how a reflexive methodological practice can shed light on past funerary practices with new inter- and transdisciplinary approaches, even from very "chaotic" bone assemblages.

6 ANIMAL ASSOCIATIONS IN HUMAN BURIALS: INSIGHTS FROM TELL MOZAN (MIDDLE BRONZE AGE, NORTHERN SYRIA)

Kharobi, Arwa (Masaryk University) - Buccellati, Federico (Freie Universität Berlin) - Kelly-Buccellati, Marilyn (California State University) - Buccellati, Giorgio (UCLA)

The funerary space at Tell Mozan, situated strategically in the northern Syrian foothills, offers valuable insights into the mortuary practices spanning four centuries from the early to late Khabur periods. Covering 1860 m², the burial ground within Urkesh's upper town reveals a diverse array of more than one hundred burials. Analysis integrating archaeological, anthropological, and archeothanatological data unveils a spectrum of funerary practices, suggesting connections to family, community, or religious affiliations.

Tombs at Urkesh delineate social ranks: the majority consist of single simple pits, potentially indicating common burial practices (61%), while uncommon tombs suggest higher social status, such as those associated with fireplaces or complete animal deposits. Notably, animal remains, like those of suidae and caprine, were deliberately interred alongside human remains, possibly serving as offerings for the deceased's journey to the Netherworld.

One exceptional discovery includes equid burials with accompanying valuable offerings, suggesting purposeful associations between human and animal burials. Such associations, observed in Tell Arbid, Mohammed Diyab and Chagar Bazar, and documented in cuneiform texts, indicate varied socio-cultural traditions or individual statuses governing burial practices. Analogous cases, such as those in Shiyukh Tahtani, reinforce the significance of these burial traditions across the Middle Bronze Age in Khabur.

The intentional placement of equidae alongside human burials underscores the symbolic and ritualistic nature of these practices. Such findings deepen our understanding of ancient burial customs, shedding light on the complexities of belief systems and social structures in Bronze Age societies in the region. The multifaceted analysis of funerary practices at Tell Mozan enriches our comprehension of the cultural and religious landscape of Urkesh, highlighting the intricate interplay between the living, the deceased, and the divine.

7 UNRAVELLING THE FUNERARY RITUAL OF THE PREHISTORIC HYPOGEUM OF CALAFORNO (GIARRATANA, SICILY) THROUGH THE STUDY OF ITS COMMINGLED HUMAN REMAINS

Varotto, Elena (Flinders University; Fapab Research Center) - Bello, Silvia (Natural History Museum, London) - Mitello, Pietro (DISUM, University of Catania) - Galassi, Francesco Maria (University of Lodz)

The present communication has its focus on the approaches utilised in the study of the commingled human remains retrieved in the prehistoric Hypogeuum of Calaforno (Giarratana, Ragusa, Sicily), a complex multi-function site built during the Late Copper Age (ca. 2600 BC) and used until the 11th century AD. In total 817 human bones, among more than a thousand animal ones, were found in 11 of the 35 chambers constituting the hypogea structure, with a calculated M.N.I. of 39 individuals. In order to analyse these remains and better identify the biological profile of the investigated individuals, various methodologies were adopted including anthropological and palaeopathological examinations, as well as palaeoradiological ones. Moreover, the remains were taphonomically investigated by evaluating the alterations caused by diagenetic processes and calculating quantitative and qualitative states of preservation.

Finally, thanks to stereomicroscopic analysis, cutmarks on some bones were detected, which leads to a discussion on the potential post mortem treatment of the cadavers in light of phenomena such as defleshing, disarticulation and cannibalism. The results suggest that the identified funerary ritual could be that of collective burials. The long human occupancy of the site with different purposes during the centuries (funerary, religious, sheltering), other taphonomical processes and looting in recent times are the main limitation in this study: these issues prevent us from determining whether also primary type burials were present. The depositions in the hypogeuum can be fully framed within the framework of collective burials - present in Italy and Sicily in the Eneolithic alongside with a great variety of other funerary rituals - some of them certainly of a secondary type, attested by the handling practices of some corpses and consistent with Eneolithic customs, perhaps evidence of specific treatment reserved only for certain individuals.

8 BOTH PARTIAL AND COMPLETE: EXCAVATIONS AND INTERPRETATIONS OF TAPHONOMICALLY COMMINGLED MUMMIFIED REMAINS FROM DIABLO WASI, PERU

Toyne, J. Marla (University of Central Florida) - Anzellini, Armando (Lehigh University)

Commingling of human remains in archaeological contexts does not just happen at the individual element level. Incomplete or partial commingling can result from original mass burial, reinterment, deliberate manipulation, or natural taphonomic processes. In any of these cases, the commingling can be only partial as remains of individuals can be found in close proximity with one another, allowing for at least a partial reassociation of the individuals included in the context. Interestingly, commingling is rarely linked with mummified remains as they are more likely to be complete individuals. However, at the site of Diablo Wasi, in the northern Peruvian highlands, this is exactly what we have recovered from open sepulchers. Sector 1 at the site consists of approximately 50 mausolea built on cliff faces. Approximately 30 and 50 individuals were deposited within two structures respectively, having undergone a process of body preparation and textile wrappings that partially and naturally mummified their remains, yet many of them were taphonomically partitioned into incomplete yet articulated skeletal materials rather than complete individuals. Within these excavated mausolea, we see two different processes leading to commingling, human-driven and natural taphonomy. Through the development of a system of excavation and documentation that maintains spatial associations between articulated and disarticulated remains we have been able to describe the taphonomic processes and gain a better understanding of potential re-association and original disposition of the remains.

9 "MOVING BONES": SPATIAL ANALYSIS OF COMMINGLED HUMAN REMAINS AT THEBAN NECROPOLIS, EGYPT AT THE AREA OF TT184

Mateovics-László, Orsolya (ARDIG Archäologischer GesmbH) - Fábian, Zoltán (Károli Gáspár University of the Reformed Church in Hungary, Department of Ancient History and Auxiliary Historical Sciences)

The investigation of Theban tombs is challenging for researchers due to their multiple usage and continuous looting, resulting in disarticulated skeletal and mummified commingled remains. However, these materials provide valuable information about the life of the ancient Egyptian elite and their funerary treatments.

Anthropological investigations of human bone material from the excavation of the Hungarian Archaeological Mission at the southern slope of el-Khoha Hill began in 2011. During the excavation, the finds were separated according to the characteristically different architectural units and the anthropological analysis followed these subdivisions.

Therefore, the assemblages were not only examined to gain information on the demographic and health profiles of the samples but also to evaluate the spatial distribution of skeletal and mummified remains. Establishing this methodological approach helped to estimate to what extent these materials are disturbed. It was intended to locate areas in the tombs where the human remains are less affected by the disturbing factors providing insight into the formation processes of the assemblages.

In this presentation, we provide an insight into how this research method could be potentially used for comparative investigations between these tombs and point at the value that such remains hold.

10 NOT ALL IS LOST. RETRIEVAL AND ANALYSIS OF A ROBBED COLLECTIVE BURIAL FROM THE AMPLERO VALLEY (ABRUZZI REGION, ITALY)

Sperduti, Alessandra (Museo delle Civiltà; Università degli Studi L'Orientale di Napoli) - Ceccaroni, Emanuela (Soprintendenza archeologia, belle arti e paesaggio per le province di L'Aquila e Teramo) - Alhaique, Francesca (Museo delle Civiltà) - Del Fattore, Francesca Romana (Soprintendenza archeologia, belle arti e paesaggio per le province di L'Aquila e Teramo) - D'Avino, Adele (Università degli Studi L'Orientale di Napoli) - Candilio, Francesca (Museo delle Civiltà) - Ceconi, Viola (Museo delle Civiltà)

In 2022, a speleological survey in the Amplero Valley led to the discovery of a "grotticella" (i.e. small cave) tomb with scattered human bones providing evidence of unauthorized excavations. The situation required the intervention of the Soprintendenza L'Aquila-Teramo in collaboration with the Museo delle Civiltà, Servizio di Bioarcheologia (Rome).

The typology of the tomb was similar to others in the same funerary area and the Abruzzi region. The excavation revealed a mixed deposit of hundreds of disarticulated and partially fragmented skeletal elements throughout the entire width and depth of the structure, likely resulting from the extreme disturbance of the burial. It also yielded dozens of faunal remains.

Osteological analyses were performed to reconstruct the primary setting of the burial as well as the subsequent post-depositional taphonomic processes. Several procedures and indexes were applied to assess the MNI, the MNE, and the BRI, followed by the reconstruction of the skeletal individualities to obtain the demographic and paleopathological profile of the individuals. The findings indicate the primary deposition of at least 11 individuals, ranging in age from 6-7 to 40+ years. Their bones exhibit varying degrees of diagenetic changes depending on the location of discovery; in particular, many skeletal elements retrieved on the surface of the deposit showed recent porcupine gnaw marks.

The few cultural artifacts retrieved in the tomb (pottery fragments, small shoe nails, and an earring), indicate a wide chronological span (1st century BCE – 7th century CE) with a possible reuse of the structure in the postclassical period. In this regard, for a better understanding of the utilization phases of the tomb, radiocarbon dating and aDNA analyses are currently underway.

The experience of Collelongo shows that when acting promptly with safeguarding actions and a well-planned multi-disciplinary study, it is still possible to reconstruct and valorize what seemed lost.

11 INSIGHTS INTO PREHISTORIC MULTIPLE BURIALS - A COMPREHENSIVE STUDY

Gémes, Anett (Department of Biological Anthropology, Eötvös Loránd University, Budapest, Hungary) - Dani, János (Department of Archaeology, University of Szeged, Hungary) - Mester, Edit (Kiss Pál Museum, Tiszafüred, Hungary) - Kiss, Viktória (HUN-REN Institute of Archaeology Research Centre for the Humanities, Budapest, Hungary) - Major, István (HUN-REN Institute for Nuclear Research, Debrecen, Hungary) - Szeverényi, Vajk (Déri Museum, Debrecen, Hungary) - Cavazzuti, Claudio (Department of History and Cultures, University of Bologna, Ravenna, Italy) - Kiss, Krisztián (Institute of Practical Methodology and Diagnostics, Faculty of Health Sciences, University of Miskolc, Miskolc, Hungary; Department of Biological Anthropology, Eötvös Loránd University, Budapest, Hungary; HUN-REN Research Centre for the Humanities, Institute of Archaeogenomics, Budapest, Hungary; Department of Anthropology, Hungarian Natural History Museum, Budapest, Hungary) - Szeniczey, Tamás (Department of Biological Anthropology, Eötvös Loránd University, Budapest, Hungary) - Hajdu, Tamás (Department of Biological Anthropology, Eötvös Loránd University, Budapest, Hungary)

The Middle Bronze Age (MBA) communities (2000-1500 BC) of the Carpathian Basin (CB) adhered to strict burial rites, even segregating individuals by gender in graves, including children. However, the discovery of a mass grave challenges these established practices, prompting questions about the underlying motivations.

In 2020, during the excavation at the site Tiszafüred-Majoroshalom III, a pit with human remains associated with the Otomani-Füzesabony cultural complex was unearthed. The estimation of the minimum number of individuals and the analysis of age and gender distributions within multiple burials were pivotal in uncovering the reasons behind the collective burial practices. To achieve this, a unified methodological review was conducted, integrating data from the contemporary cemetery and utilizing advanced anthropological and paleopathological techniques commonly employed in multiple burial analyses.

This comprehensive approach aimed to determine whether factors such as intergroup conflict or intragroup violence, or the prevalence of epidemic diseases, influenced the adoption of multiple burial practices within these community. In addition to traditional anthropological examination methods, stable isotope analyses were employed to provide insights into diet and potential migration trends, further enriching our understanding of this special burial context.

By shedding light on the complexity of MBA multiple burials, this study contributes to our knowledge of the social and cultural dynamics of Bronze Age communities in the CB.

Project No. C2284509 has been implemented with the support provided by the Ministry of Culture and Innovation of Hungary from the National Research, Development and Innovation Fund, financed under the KDP-2023 funding scheme. The project was also supported by the grant of the Hungarian Research, Development and Innovation Office [proj. id.FK128013], the Bolyai Scholarship of the Hungarian Academy of Sciences and the ÚNKP-23-5 New National Excellence Program of the Ministry for Culture and Innovation from the source of the National Research, Development and Innovation Fund.

12 FROM FLESH TO MESS: DISENTANGLING COMMINGLED AND FRAGMENTED HUMAN REMAINS AT THE NEOLITHIC/CHALCOLITHIC BURIAL OF CUEVA DEL CABALLO, SOUTHWESTERN IBERIA

García-Domínguez, Celia (Universidad de Valladolid; Fundación Extremeña de la Cultura) - Fernández-Crespo, Teresa (Universidad de Valladolid; University of Oxford (United Kingdom)) - Collado Giraldo, Hipólito (DG de Bibliotecas, Archivos y Patrimonio Cultural. Junta de Extremadura)

Commingled and fragmented skeletal remains are challenging components of many anthropological analyses. This is particularly problematic in the Neolithic and Chalcolithic, where cumulative funerary practices often result in chaotic and poorly preserved skeletal assemblages. Analytically, the state of preservation of the remains is tied to the complexity of the methodological approach required to obtain valuable anthropological information. The poorer the former, the more complex the latter.

This is the case of Cueva del Caballo site, located in southwestern Iberia. The cave has been used for burial from the Early Neolithic to the Early Bronze Age. However, here we focus on the Neolithic/Chalcolithic funerary deposit, dated around 3611-2662 cal. BC. Here, we present the methodological approach used to explore the funerary practices and reconstruct the lifeways of those buried at the site. This includes a number of conventional analyses not only on human remains (Anthropologie de terrain, human osteology, taphonomy, radiocarbon dating), but also on their archaeological context through the study of associated materials (grave goods, macro- and micro-faunal remains, sediments...). We also present future prospects for exploring Cueva del Caballo through molecular methodologies such as isotope and DNA analyses as promising means that can provide a deeper and more detailed understanding of the community buried. This proposal may serve as a key example of how an optimized methodology can challenge ideas of the limited informative value of commingled and fragmented human remains and reveal significant aspects of our ancestral history.

13 THE MEGALITHIC SIEVE: SEX ESTIMATION IN FRAGMENTARY HUMAN REMAINS OF MEGALITHIC TOMBS FROM THE SPANISH NORTHERN PLATEAU THROUGH PROTEOMIC ANALYSIS

Santa Cruz, Angelica (Universidad de Salamanca. Dept. de Prehistoria, Historia Antigua y Arqueología.; Universidad de Valladolid. Dept. de Prehistoria, Arqueología, Antropología Social y CC. TT. Historiográficas.) - Fernández-Crespo, Teresa (Universidad de Valladolid. Dept. de Prehistoria, Arqueología, Antropología Social y CC. TT. Historiográficas.; University of Oxford. School of Archaeology.) - Casas-Ferreira, Ana María (Universidad de Salamanca. Dept. de Química Analítica, Nutrición y Bromatología.) - del Nogal-Sánchez, Miguel (Universidad de Salamanca. Dept. de Química Analítica, Nutrición y Bromatología.) - Pérez Pavón, José Luis (Universidad de Salamanca. Dept. de Química Analítica, Nutrición y Bromatología.) - Villalobos García, Rodrigo (Universidad de Valladolid. Dept. de Prehistoria, Arqueología, Antropología Social y CC. TT. Historiográficas.) - Moreno Gallo, Miguel (Universidad de Burgos. Dept. de Historia, Geografía y Comunicación.) - Basconillos Arce, Javier (Asociación Geocientífica de Burgos.) - Delibes de Castro, Germán (Universidad de Valladolid. Dept. de Prehistoria, Arqueología, Antropología Social y CC. TT. Historiográficas.)

Sex estimation of individuals recovered from contexts of commingled and fragmentary human remains usually faces many methodological difficulties and practical limitations. These features often affect skeletal assemblages from Late Neolithic and Chalcolithic collective burials. Despite the aforementioned constraints, in the megalithic tombs of northern Spain, some sex-related demographic anomalies favouring adult males have been detected through osteological analysis, which has been interpreted as evidence of selective burial practices. However, the representativity of the data is unclear due to poor bone representation and the impossibility of estimating the sex in non-adults.

Recent studies have demonstrated the accuracy of mass spectrometry-based peptide analysis in dental enamel for biological sex determination. This study is pioneer in applying a new fast method based on dimorphic peptide analysis to a megalithic collection. A total of 85 individuals from five tombs of the megalithic group of La Lora (Spanish northern plateau), representing all age groups, were analysed. The molecular assignment of biological sex has allowed a reliable approach to the sex ratio. This study confirms a general predominance of males, although variations in sex

ratios linked to the temporal use of the graves should be considered. This fact seems to reflect previously unknown diachronic changes in the politics of the death.

14 **THE VALUE OF SCATTERED AND FRAGMENTARY HUMAN REMAINS: CASE STUDIES FROM NEOLITHIC SETTLEMENT MOUNDS ON THE GREAT HUNGARIAN PLAIN**

Anders, Alexandra (Eötvös Loránd University, Institute of Archaeological Science) - Füzesi, András (Hungarian National Museum) - Hajdu, Tamás (Eötvös Loránd University, Department of Biological Anthropology) - Köhler, Kitti (Hungarian Natural History Museum) - Raczy, Pál (Eötvös Loránd University, Institute of Archaeological Science)

Fragmentary human remains have rarely attracted the attention of either archaeologists or osteoarchaeologists: the former generally tend to focus mainly on complete burials. Thus, the study and discussion of disarticulated human bones are usually omitted from their analyses, and we are often left without any information even about their occurrence on a particular site since they are often treated as stray, unstratified, worthless and uninteresting finds.

Presented and discussed here as case studies are the fragmentary human remains from three remarkable Late Neolithic (5th millennium BC) settlement mounds: Polgár-Csőszhalom, Polgár-Bosnyákdomb and Öcsöd-Kováshalom. All three sites yielded human remains, either wholly intact or articulated, as well as in the form of scattered fragments. Fortunately, the latter were also submitted to an osteoarchaeological examination and we thus have information on the type of bones and, in several cases, a rough estimate of the age at death. In some cases, peri- and post-mortem cut marks were observed on the bones. We collated this information with the contexts and exact findspots of the fragmented human bones as well as with their spatial scatter.

These data offered valuable insights into the mortuary rituals of the given communities and of their attitudes to human bodily parts after the disintegration of the body. Were the remains of their ancestors deposited intentionally or was it coincidental? These practices differed on the three sites, highlighting the need for undertaking the examination of finds of this type on all sites in future research because they offer fresh information that shed entirely new light on human remains, and contribute to a better understanding of past societies. A close collaboration and dialogue between archaeologists and osteoarchaeologists is therefore indispensable in future studies.

The archaeological assessment of the Polgár-Csőszhalom site is funded by a grant from the NRD Fund (Grant K124326).

15 **PERI-MORTEM TRAUMA, POST-MORTEM DAMAGE AND THE IN-BETWEEN: EXPLORING PATTERNS OF FRAGMENTATION IN IRON AGE BRITAIN**

Castells Navarro, Laura (University of York) - Armit, Ian (University of York)

In the analysis of archaeological human remains, fragmentation is often considered to be the result of random post-mortem events happening when bone was already dry. But is it always so?

This paper presents the results of the analysis of the human remains from two British Iron Age sites, analysed as part of the COMMIOS Project: Applecross, northwest Scotland, and Danebury, southern England. At Applecross, at least seven adult individuals were buried within and below a low mound of beach cobbles. The analysis of the fragmented and commingled remains revealed repeated (fragmented) skeletal elements, breaks with intermediate peri-post-mortem characteristics, and the presence of impact and chisel scars. These findings suggest that (at least part of) the fragmentation observed in the remains was intentional or guided. In contrast, at Danebury hillfort human remains were deposited in pits in what are recognised to be over 400 individual deposits. The analysis of all the deposits reveals a possible differential peri-mortem and post-mortem treatment and manipulation of the human remains deposited as complete bodies, a partial individual, or single skeletal elements.

In both cases, it is possible that intentional fragmentation or processes which increased the likelihood of bone breakage were part of protracted funerary practices and points to complex interactions between the living and the dead.

16 **FRAGMENTED RITUAL: THE POTENTIAL OF DISARTICULATED HUMAN REMAINS FOR UNDERSTANDING MINORITY MORTUARY TREATMENT IN ROMAN BRITAIN**

Green, Ellen (University of Reading)

Disarticulated human remains are often dismissed as a poor source of osteological information, as problems with individuation severely limit the effectiveness of many types of analysis. This is particularly notable within Romano-British contexts, where the “un-Roman” nature of the material often leads to it being interpreted as an isolated oddity, disturbance of earlier graves, or a hold-over from Iron Age practices. As a result, disarticulated material from this period is often not analyzed or reported on in any detail, despite it being relatively common throughout the entire Roman period.

This paper will present a case study of a large assemblage (NISP=672, MNI=20) to show the potential of disarticulated human remains for recognizing and understanding complex mortuary practices. Micro and macro taphonomic analysis of an assemblage of disarticulated human remains from a first century A.D. quarry from the Nescot Former Animal Husbandry Centre in Ewell, Surrey showed evidence of multi-stage post-mortem processing. This included decomposition of the remains within a protected environment followed by removal of certain skeletal elements. This level of interaction with the dead is previously unrecognised within the Romano-British archaeological record, and shows the potential of disarticulated remains for identifying and understanding mortuary ritual.

17 **SCATTERED AND COMMINGLED HUMAN REMAINS AS A SIGN OF CARE AND BELONGING**

Gramsch, Alexander (RGK - Romano-Germanic Commission DAI)

Features containing single human bones or fragmented and commingled body remains are quite common in the archaeological record for all periods. Based on our project on “The Itinerary of the Human Body” focusing on examples of continued interaction with the body, this contribution brings together a variety of evidence to consider the social role of the human body as well as the social practices that resulted in fragmented bodies and intermingled body parts. Rather than assuming a disturbance of an original context of interment, many features can be understood as resulting from a deliberate and recurring engagement with the body. Since our investigation draws on the phenomenology and sociology of the human body, we approach the body as both a physical ‘thing’ and as a social phenomenon with which individuals and groups must engage; the individual acts through the body and, in turn, the body is acted upon, beyond the death of the individual. Much of the current research considers human remains as a passive container of information on nutrition, health, mobility, and ancestry; however, beyond this, the human body needs to be understood as a medium of social relations and a means of maintaining and transforming relationships. This is also enabled by the general partibility of the body. Thus, scattered and commingled human remains can be a sign of body-related practices linked to coping with loss and the need to (re-)organise social relationships over time, and to care and the wish to create bonds both between the deceased and the bereaved as well as among the living.

18 **BARCZEWKO: UNCOVERING AN ABANDONED MEDIEVAL TOWN THROUGH ARCHAEOOMETRY AND MORTUARY ARCHAEOLOGY**

Cuello del Pozo, Paloma (Texas A&M University) - Koperkiewicz, Arek (University of Gdansk)

Barczewko is a town situated in Poland’s Warmia region, where Prussian tribes dwelled until its occupation by the Teutonic Order. According to medieval chronicles, the town, initially named Wartenberg and established by a bishop, primarily attracted settlers from the German area of Silesia. Its demise came tragically when Lithuanian invaders destroyed it. Since 2014, field research has uncovered compelling evidence including layers of burned structures akin to the archaeological “Pompeian case,” indicating a sudden assault as retold by ethnohistorical sources. A cemetery dating from 1330-1354, potentially containing the remains of indigenous groups and German settlers, further enriches our understanding of the populations and religious syncretism that took place during the merging of distant peoples. With the collaboration of interdisciplinary teams, our research explores migration trends to better understand the settlement patterns that occupied Medieval Barczewko. We analyze stable isotopes of strontium (87Sr/86Sr), oxygen (d18O), and carbon (d13C) from human bone and tooth remains from Barczewko burials. We also compare human data to biologically available 87Sr/86Sr measurements from zooarchaeological remains. Preliminary 87Sr/86Sr results suggest that a portion of the population was local, implying a cultural blending upon the establishment of Wartenberg by German settlers. This cultural amalgamation is further evidenced in the funerary practices excavated, with individuals interred by traditional Christian burial customs, along with ceramic offerings perhaps indicating the identity of neophytes. In our effort to deepen our comprehension of the cultural milieu in Warmia during the Teutonic Order era, our presentation will provide new stable isotope findings. These results will also significantly enhance the existing dataset for isoscapes in the region, offering valuable insights into its historical and cultural landscape.

Research funded by the National Science Center, project 2021/41/B/HS3/01694 titled “Barczewko – A History Written by Fire. The Medieval Lost City and Urbanization of the Galindian Forest” 2022-2024.

19 **AN ANALYSIS OF COMMINGLED HUMAN REMAINS FROM TWO BRONZE TO IRON AGE SITES IN WEST TIBET**

Cao, Doudou (Department of Archaeology, University of Cambridge, United Kingdom) - Pomeroy, Emma (Department of Archaeology, University of Cambridge, United Kingdom) - Lu, Hongliang (School of Archaeology and Museology, Sichuan University, P.R. China) - Yuan, Haibing (School of Archaeology and Museology, Sichuan University, P.R. China) - Yang, Feng (School of Archaeology and Museology, Sichuan University, P.R. China) - Li, Shuai (School of Archaeology and Museology, Sichuan University, P.R. China)

The limited study of ancient Tibetan populations at high altitude leaves significant gaps in our understanding of their growth and adaptation to such challenging environments. This investigation is further complicated by the presence of

commingled remains in archaeological sites, requiring careful analytical approaches. This study examines commingled remains from two Bronze-Iron Age sites in west Tibet, Piyangdungkar and Sdingchung, with the former featuring discrete graves and the latter a mass cave burial. It involves the analysis of demographic data and dental pathology, together with the reconstruction of stature, body mass, and limb proportions to explore the body form of ancient Tibetans. Anatomical stature (ASTA) and morphometric body mass (MPBM) were also built as the benchmark for testing the applicability of existing equations.

Results indicated an MNI of 68 in 49 burials at Piyangdungkar and of 54 at Sdingchung. The Piyangdongkar adults displayed a lower tooth caries rate (4.4%) but significant dental wear and frequent antemortem tooth loss (AMTL) compared to other ancient Chinese, while Sdingchung remains showed no dental caries but prevalent AMTL. The individuals exhibited a small body size, with a mean stature of 145 cm and body mass of 47 kg for females, and 158 cm and 70 kg for males. Previous stature equations for Northern European and North American Arctic populations better predicted the ASTA than other methods, as did the European body mass equation in predicting the MPBM. Although the sample size is limited, these findings align with body proportions (relatively short lower limb and tibia lengths and wider bodies) in study remains, resembling those of Northern European and Arctic populations.

Despite challenges inherent to commingled remains, this study is informative regarding analytical approaches and provides valuable insights into the health and growth of past populations within the distinctive setting of the Tibetan Plateau.

20

THE VALUE OF FRAGMENTS – ETHICAL VIEWS ON THE CURATION AND RESEARCH OF PROBLEMATIC HUMAN REMAINS

Seppanen, Liisa (University of Turku; University of Helsinki) - Ermala, Jenna (University of Oulu)

The curation and research of fragmentary and commingled human remains involve various ethical questions that are widely understood and considered in archaeology and bioanthropology and manifested in various guidelines. However, practical challenges often present ethical dilemmas. Ethical views need to be weighed against limited resources, unequal treatment of research materials, and research potential for future scientific inquiry.

This presentation roots into the ethical considerations arising from pragmatic challenges to preserve and study fragmented and commingled human remains in Finland. Notably, when the remains date from historical periods. With few examples and studies we are addressing the questions of value and ethics while acknowledging our limited possibilities as researchers to affect the prevailing practices defining future studies. We must critically examine the reasonings, ethics and implications of prioritizing certain human remains over the others, particularly when fragmentary and commingled bones are sidelined due to limited resources or perceived of minor scientific value and research interest.

Since the decisions – starting from collection policies and often justified by ethics – are based on the comprehended values of the remains and views on the research potential, we are calling for open and deeper discussions about the value judgement and ethical aspects entwined in this issue and on the other hand encouraging the experts to develop advanced methodologies for studying fragmented remains. By encouraging dialogue to improve equitable curation processes, raising awareness of methodological challenges, and acknowledging the complexities of fragmented and commingled materials, we aim to promote ethical accountability. This advocates for more inclusive and ethically informed approaches to fragmented human remains research and curation processes.

1133 EVERYTHING COUNTS IN LARGE AMOUNTS? THE EMERGENCE OF TRADE NETWORKS IN MEDIEVAL EASTERN EUROPE. THE ARCHAEOLOGICAL AND ARCHAEOMETRIC EVIDENCE

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Khamaiko, Natalia (The Leibniz Institute for the History and Culture of Eastern Europe (GWZO); The Institute of Archaeology, National Academy of Science of Ukraine) - Woloszyn, Marcin (The Leibniz Institute for the History and Culture of Eastern Europe (GWZO); University of Rzeszow) - Komar, Oleksii (The Institute of Archaeology, National Academy of Science of Ukraine)

Session format: Regular session

The scarcity of written records from East Central and Eastern Europe in the early Middle Ages means that archaeological and archaeometric research is becoming increasingly important in the study of trade relations. Today, science offers opportunities to enter into broader fields of research. Petrographic, isotopic and material science research can shed light on the origin of objects. Furthermore, aDNA studies can prove the migration of animals or goods. Our aim is to discuss the state of the art of trade research for pre-Mongol East Central and Eastern Europe. In the case of some commodities, we have evidence of their mass circulation. They prove that the medieval world was more open than we thought until recently.

We would like to consider both special and mass finds, those that united the elite (e.g. jewellery, ivory, gemstones, silk, amphorae) and the common people (ceramic, glass, Ovruch slate).

We will discuss methods of identifying imported products and mechanisms of exchange, and ask to what extent they can be taken as evidence of medieval globalisation.

ABSTRACTS

1 LONG-DISTANCE CONTACTS THAT PASSED THROUGH BOHEMIA IN THE 7TH - 9TH CENTURIES

Profantová, Nadezda (AU - Institute of Archaeology of the Academy of Sciences of the Czech Republic)

In the 7th century, Bohemia was mainly connected to the Silk Road to Eastern Europe and the Caucasian area. There were also important connections to the southeast – to the Carpathian Basin and the Balkans. The Frankish merchants as well as the armed conflict with the Frankish Empire (631/2) are better documented by written sources than by archaeology. Archaeology then proved the contact with Crimea and less noticeably with Baltic countries (amber). In the 8th century, the ties to the Carpathian Basin and South Europe (Dalmatia, Byzantine Empire) became more pronounced and at the end of the century the significance of the Carolingian Empire in the network of contacts changed – that is when the Carolingian coins began to circulate. At the same time, there were Carolingian campaigns into Bohemia (805, 806, 847-9) and Regensburg's importance as the closest western metropolis had increased. Sporadically, even Arabian coins made it to Bohemia (from north or northwest?). From the last third of the 9th century, we have evidence of the interconnectedness of Bohemian and Great Moravian elites (Kolín, Kourim, Želénky, Praha). This corresponds with a short-term political connection to the Great Moravian Empire. At the end of the 9th century, the close connection with Regensburg was restored.

2 THE PLACE AND ROLE OF THE CARPATHIAN BASIN AND EARLY HUNGARIANS IN THE RESURGENT LONG-DISTANCE TRADE OF EURASIA (9TH-10TH CENTURY)

Harangi, Flórián (Hungarian National Museum, National Institute of Archaeology) - Jancsik, Balázs (HUN-REN Research Centre of Humanities, Early Hungarians Research Team; Pázmány Péter Catholic University, Institute of Archaeology) - Türk, Attila (HUN-REN Research Centre of Humanities, Early Hungarians Research Team; Pázmány Péter Catholic University, Institute of Archaeology)

The Avar Khaganate were able to join the re-emerging European commerce from the 8th century onwards, but in the middle of the 9th century, the political power of the Avars ceased. The Carpathian basin at the beginning of the 10th century was reunified by the early Hungarians. Their graves are bound in precious metal objects and luxury goods. The parallels of these metal fittings occur in Scandinavia and the Rus, but these are concentrated in the Volga-Ural region, where we can assume the former settlements of the early Hungarians and their groups, who remained in the East. The connection between these groups is also confirmed by aDNA studies. The demand for products of Hungarian-style toreutics was high in the period, these objects appeared in the Trans-Urals region too.

In addition to silver objects, silks are often found in the old Hungarian graves. Some of these silks may have been acquired as part of the booty of the Western European campaigns, other parts of them may have been commercial products. Eastern Hungarian communities may also have played a role in the mediation of silk from the Muslim world.

The ray skin on the handle of 10th-century sabres could also have been an important product of the trade, which came from the East. The custom of covering the handle of weapons with ray skin can be traced to the Far East.

In addition to the import objects, we must also pay attention to the exports flowing from the Carpathian Basin to the East, which on the one hand consisted of the already mentioned precious metal objects. Based on the written sources and later parallels, we can count on the export of live animals and possibly salt.

The dirhams also draw attention to the importance of eastward commercial connections of the Carpathian Basin.

3 MEDIEVAL GLOBALISATION? FOLLOWING THE AMBER TRADE BETWEEN THE BALTIC, RUS' AND CENTRAL ASIA

Damm, Carina (University of Silesia)

Contrary to the well-researched long-distance trade of the Bronze Age and the Roman period, trade in amber during the Viking Age (c. 750-1050) and the high Middle Ages (c. 1000-1300) has hitherto received less focus. Aiming to bridge this gap, this paper investigates the circulation of amber in three core regions that formed part of an interconnected medieval world. Firstly, Scandinavian and Slavic emporia on the Baltic and North seas, such as Wolin (where about 100 kg of amber artefacts and raw material have been found) or Ribe (where more than 10,000 finds were unearthed). Secondly, in medieval Rus', beads from the Baltic, but also Byzantium and the Islamic countries, reveal further insights into medieval trading connections, illustrated by the find of over a thousand pieces of amber

in Novgorod. A final area of study will be Central Asia where aristocratic burials of the Liao dynasty from the early eleventh century contained numerous amber items. Infrared spectroscopy could identify their Baltic provenance from where it was imported as far as to China via Khwārizm and Volga Bulgaria by the Turkic Qarakhanids. What then made the material so desired both in the Baltic and far beyond? In which context do the objects stand to other trading commodities such as furs, silver dirhams, or slaves? Drawing upon both archaeological and historical methods, the paper thus explores the provenance of amber and its circulation, aiming to expand our knowledge on mobility of people, ideas, and goods in a globalised medieval world.

4 THE MORE YOU GET - THE BETTER - THE CONTRIBUTION OF AMPHORAE TO STUDYING TRADE NETWORKS IN MEDIEVAL EASTERN EUROPE

Todorova, Evelina (National Archaeological Institute with Museum, BAS)

Amphorae were ceramic containers that were used for the long-distance transport by ships of bulk agricultural goods such as wine and olive oil. They are considered as an evidence of economic contacts between different regions and can be used in the reconstruction of trade relations. During the 7th -14th c. amphorae were mainly produced in territories that made part of the Byzantine Empire. Since the 10th c. amphorae typologically belonging to different classes and production centers appear in large quantities in present-day North-Eastern Bulgaria, the Northern Black sea coast area and in the territories of the newly established Kievan Rus'state, reaching as north as southern Sweden, following the course of larger and smaller rivers such as the Dnieper, Dniester, etc. Using mapping amphora finding spots as a method for extracting important information will allow to outlining distribution networks and making conclusions about the nature of the commercial contacts (direct, indirect, state, private, etc.).

5 AMPHORAE IN RUS'. APPROACH TO EXCHANGE PATTERNS THROUGH THE PETROFABRIC DISTRIBUTION

Korokhina, Anastasiia (Leibniz Institute for the History and Culture of Eastern Europe (GWZO), Leipzig, Germany; Institute of Archaeology, National Academy of Sciences of Ukraine, Kyiv, Ukraine) - Khamaiko, Natalia (Leibniz Institute for the History and Culture of Eastern Europe (GWZO), Leipzig, Germany; Institute of Archaeology, National Academy of Sciences of Ukraine, Kyiv, Ukraine) - Wołoszyn, Marcin (Leibniz Institute for the History and Culture of Eastern Europe (GWZO), Leipzig, Germany; University of Rzeszów, Poland) - Waksman, Sylvie Yona (CNRS UMR5138, laboratory "Archaeology and Archaeometry", Lyon, France) - Trzeciecki, Maciej (Institute of Archaeology and Ethnology Polish Academy of Sciences, Warsaw, Poland) - Tymoshenko, Mariia (Museum of Kyiv History, Kyiv, Ukraine) - Auch, Michał (Institute of Archaeology and Ethnology Polish Academy of Sciences, Warsaw, Poland) - Chernenko, Olena (University of Warsaw, Poland; Chernihiv Taras Shevchenko National Teachers' Training University, Chernihiv, Ukraine) - Baiuk, Viktor (Subsidiary Research Centre "Security Archaeological Service of Ukraine" of the Institute of Archaeology of the National Academy of Sciences of Ukraine, Kyiv, Ukraine) - Kolybenko, Oleksandr (National Historical and Ethnographic Reserve "Pereiaslav", Pereiaslav, Kyiv region, Ukraine)

Amphora finds are one of the sensitive and mass indicators of cultural, economic and political links within Medieval Europe. In the 10th – early 13th century they appeared massively in the cities and rural settlements of Kyivan (Early) Rus' as a result of Rus' adoption of orthodox Christianity and intensified contacts with the Byzantine Empire.

This study presents the first generalisation of a petrographic investigation of amphorae dating back to the 10th – early 13th century from several urban centres of Rus' – Kyiv, Chernihiv, Pereiaslav, Volodymyr, Cherven'/Chermno, as well as Kraków, the capital of Piast Kingdom in Poland. The initial systematisation of petrographic data allowed a preliminary assessment of the intensity of imports, the identification of regional distribution patterns and, in conjunction with chemical analysis data, the association of some of the petrogroups with Mediterranean centres of amphora production.

The amount of material and diversity of petrofabrics (i.e. groups united by common features of raw materials and technology), allow us to assess the role of the sites in the system of the Mediterranean-Black Sea trade, which varies from a major trading hub (Kyiv) to peripheral centres (Cherven'/Chermno). The petrogroup associated with the production of amphorae of types Günsenin IV, and of Günsenin I from Ganos is the most widespread so far; the participation of Chalcis and other, undetermined, centres has also been noted. The origin of a large number of petrographic groups needs to be clarified.

6 EASTERN CURIOSITIES AND WESTERN NOVELTIES. IMPORTED POTTERY IN EARLY MEDIEVAL POLAND – AN OVERVIEW

Trzeciecki, Maciej (Institute of Archaeology and Ethnology, Polish Academy of Sciences) - Auch, Michał (Institute of Archaeology and Ethnology, Polish Academy of Sciences)

Clay vessels were rarely the subject of long-distance trade in pre-modern Europe. This was primarily due to their physical properties – fired clay is not very resistant to long-term transport conditions. The only exception here are amphorae – clay containers for wine and olive oil, widely distributed throughout the Byzantine Commonwealth. Hence, finds of imported pottery can be considered significant evidence in the studies of trans-regional connections of early medieval East-Central European communities.

This paper raises the issue of early medieval ceramic imports in Poland (9th-13th centuries). The territory in question covers not only the core area of the Piast state but also the western border of Kyiv Rus' and the independent polities of the southern Baltic coast. Such an approach puts investigated phenomena in a broader East-Central European context. Issues discussed will include categories of finds (amphorae, Islamic tableware, Rhineland wine jugs, graphite pots, etc.), their distribution (Baltic sea emporia, power centers, strongholds, villages), identification of imports (stylistic analyses, archaeometric research). Interpretive frames of the imported pottery is also of great importance here. Most often, we regard the presence of imports as evidence of trade. However, attention should also be paid to other types of mobility (migrations, travels, pilgrimages) and the political sphere (diplomatic gifts).

Given the current state of the research, the observations presented here are only preliminary, but they set out the great, although still not recognized, cognitive potential of this category of finds.

7 TO THE ELITE TASTE: BEYOND THE COSTS AND AESTHETICS. GLAZED TABLEWARE IMPORTS FROM MEDIEVAL KYIV

Tymoshenko, Mariia (Museum of Kyiv History (Kyiv, Ukraine))

In the period of 10-13th centuries, Kyiv obtained an exceptional role in the political and economic system of the Early (Kyivan) Rus'. Due to the geographical location on the Dnipro waterway, the medieval city served as a transit hub for Byzantine imports and the dominant center of consumption for elite products. While numerous amphorae were delivered to the urban and even rural centers of Rus', the glazed pottery constituted insignificant quantity and were unlikely to have economic relevance by means of merchandise goods in the framework of certain trade relations. The paper presents an overview of the corpus of Byzantine glazed pottery retrieved from the archaeological deposits of princely Kyiv and aims to consider it as a case data set in the context of cross-cultural and long-distance contacts of Rus', in particular with Constantinople and besides that to determine it in terms of socio-cultural space, specific features of historical topography and daily life of the medieval city.

8 MEDIEVAL AND MODERN GLAZED ITALIAN WARE IN THE NORTHERN BLACK SEA REGION

Teslenko, Iryna (Institute of Archaeology NAS of Ukraine, Kyiv; Philipps University Marburg)

The earliest finds of Italian glazed ceramics in the Northern Black Sea region date back to the second half of the 13th century which quite coincides with the rise of activity of Italian merchants in this area.

However, despite the dominance of Italians in the maritime trade of the following two centuries, ceramic imports from their homelands never became numerous. Finds of Italian ceramic are quite rare even in large commercial cities such as Azak (modern Azov), Sugdeya (Sudak), Kaffa (Theodosia), Cembalo (Balaclava), Moncastro (Bilhorod-Dnistrovskiy).

The late 13th and 14th century finds include Graffita Arcaica Tirenica, Roulette Ware; Maioliche Arcaiche; RMR, etc. It seems that all of them were more personal belongings than commercial goods.

This may seem surprising, but the number of Italian ceramics on the Northern Black Sea coast increased after the Ottoman conquests of the region in the last quarter of the 15th century, despite Italians having lost their former advantages there. There were mainly Renaissance majolica and Renaissance sgraffito of various types and origins. For this time, it seems that besides personal belongings, they could already be a trade item or a special gift.

My presentation focuses on a detailed analysis of Italian ceramics of the 13th–17th centuries from the Northern Black Sea area. I will also address the issue of the dynamics of their arrival to the region and the reasons for its fluctuations.

9 BEHIND BLUE GLASS: A HISTORY OF BYZANTINE IMPORT IN MEDIEVAL KYIV (ACCORDING TO ARCHAEOLOGICAL DATA)

Zhurukhina, Olena (The Museum of History of the Desiatynna (Tithe) Church (Kyiv, Ukraine))

During the Middle Ages Kyiv, as the administrative, political, cultural, and economic centre of Rus', accumulated processes that contributed to the development of internal and external trade relations and was also known for the

trade routes that passed through it. Kyiv medieval glass is quite diverse and represented by a wide range of products (vessels, jewellery, items for decorating religious building's interior – mosaic tesserae, lamps, window glass). Imported glass finds are not widespread, but they are informative, and promising for further study. Such objects usually arrived as part of ambassadorial gifts, diplomatic missions, or trade agreements.

The earliest imported objects are few and unique and were found exclusively in rich burials of the late 10th and early 11th centuries, associated with the elite, sometimes warriors and merchants. The turn of the 10th and 11th centuries is marked by the predominance of jewellery made in glass workshops in the Middle East and Egypt, but there is a gradual tendency to replace them with Byzantine products. From the 11th century, the range of products diversified, with a marked increase in imported glassware, beads, and bangles. They were made of high quality, mostly blue cobalt glass, sometimes richly decorated (for example, cups of high artistic level for ceremonial feasts). Most of the objects are recorded in the cultural layers of the 11th and 12th centuries, but in the 13th century they were still in use.

A comprehensive further study of glass with signs of Byzantine production, attention to workshops that arose in connection with the construction of churches for interior decoration according to Byzantine customs – all this can help to resolve the issue of the influence of Byzantine glassmaking traditions on the emergence and development of local crafts, the development and directions of trade, cultural and political processes, diplomatic relations, etc.

10 SLAVS AND EARRINGS IN THE HIGH MIDDLE AGES: SOCIO-ECONOMIC ASPECTS OF SO-CALLED VOLHYNIAN AND BEADED FILIGREE EARRINGS IN EASTERN EUROPE

Radišić, Milica (Institute of Archaeology, Belgrade)

In contrast to the Germanic peoples, for example, the practice of wearing earrings as headdress jewellery was particularly popular among the Slavs during the Early and High Middle Ages. Earrings represent one of the most numerous categories of metal finds in the archaeological material in Central, Eastern and South-Eastern Europe. Many types and variants of them have been described in archaeological literature since the beginning of the 20th century. The paper will discuss the finds of Volhynian raceme earrings and beaded filigree earrings which were widespread in the aforementioned regions between the 10th and the 12th century. Volhynian earrings were created in the workshops of Kievan Rus', while the origin of the second type is probably in the territory of West Slavs in Poland. Both types of earrings became popular, to a certain extent, in Pannonia and the central Balkans. We can assume that luxury jewellery was also produced in these territories, mostly inhabited by the Pannonian Slavs and South Slavs (along with the Hungarians and others), however, there are more reliable material data on the production of modest cast imitations. In this respect, we would like to address the following topics: problems of identification of imported and locally produced items, the nature of links between Kievan Rus' and Poland with the regions to the south and also the possibility of the existence of a peculiar identity of Slavic elites in a wider European context on the basis of jewellery.

11 KRIVICHS ON VIKING AGE TRADE ROUTES: FINDS OF THE SMOLENSK-POLACK LONG BARROWS CULTURE FEMALE ORNAMENTS AS MARKERS OF INTERREGIONAL EXCHANGE

Plavinski, Mikalai (University of Warsaw)

As markers of the formation and intensity of the functioning of transregional trade routes in Eastern Europe in the last centuries of the 1st millennium AD, either finds of Arabic silver coins or imported Eastern, Byzantine or Scandinavian artefacts are usually used. In turn, locally made items originating from the Slavic archaeological cultures of the forest zone of Eastern Europe are rarely used as evidence of interregional trade. Such neglect of Slavic material culture objects by researchers of early medieval trade is explained, first of all, by the very nature of Slavic material culture, which was characterised by exceptional inexpressiveness and poverty. Nevertheless, it seems that also objects of Slavic material culture, in particular, the Smolensk-Polack Long Barrows Culture (SPLBK) have a certain information potential for studying the issues of interregional trade.

SPLBK is associated with the Slavic tribe of Krivichs (Kryvichs), known from written sources. The formation of the SPLBK dates back to the middle of the 8th century, and the period of its existence covers the second half of the 8th, 9th and 10th centuries. In the western part of the area the population of the culture preserved its traditions until the beginning or the first half of the 11th century.

The most characteristic elements of SPLBK material culture are considered to be a certain type of handmade pottery and a set of female ornaments. Some of these ornaments (temple rings with sickle-shaped ends, three-hole chain holders and round ornamented plaques) were characteristic only for the SPLBK. Their finds outside the culture area can be regarded as Krivichs "exports". The paper is devoted to the study of the distribution and chronology of such ornaments outside the SPLBK area. The analysis of the finds allows us to determine the main directions of Krivichs contacts.

12 BONE OBJECTS IN THE CONTEXT OF CULTURAL AND TRADE CONNECTIONS OF EARLY RUS

Serhieieva, Maryna (Institute of Archaeology NAS Ukraine)

The study of bone objects in the context of trade and cultural relations of Rus' is one of the problems that need further analysis.

The issues for consideration are:

- The place of imported raw materials in the local bone-carving craft and their origin;
- Imported bone items or bone items made after imported models.

Valuable kinds of bone raw materials were considered to be ivory (walrus and elephant tusks), which could only be imported in Rus'. They were used only sporadically. Walrus tusks (fish tooth in Rus' chronicles), which were of Northern European origin, and a few objects made of them are known archaeologically. But elephant tusks were mentioned only in written sources as an indicator of luxury. These references are mainly related to originally Byzantine literature, so it is difficult to talk about the spread of this tradition among the Early Rus' social elite. It is possible that a small amount of ivory was supplied to Rus' for elite products, but we do not yet have specific materials to specify this assumption. Icons and other objects made of ivory found in the territory of Rus' are sporadic finds of non-local origin.

There are a few types of bone objects (e.g., buttons, supposedly fish-shaped needles and some other items) that may have been trade items, but in most cases bone products made out of local tradition were not numerous and do not fall under this definition. They could have come to Rus' as a result of cultural contacts. Such items came to Rus' with their owners, such as pilgrims, merchants, visiting priests, etc. Some of bone objects also could be products of itinerant craftsmen.

13 THE „HACKSILVER HOARDS“ IN THE CARPATHIAN BASIN OF THE 10TH-11TH CENTURIES

Langó, Péter (Institute of Archaeology HUN-REN Research Centre for the Humanities; Institute of Archaeological Sciences Pázmány Péter Catholic University, Faculty of Humanities and Social Sciences) - neválovits, Anna (Institute of Archaeological Sciences, Pázmány Péter Catholic University, Faculty of Humanities and Social Sciences)

The hacksilver (broken silver) treasure hoards are an important archaeological group of finds from the 10th to 13th centuries in Northern, Central, and Eastern Europe. These hoards are named after the notable feature of containing pieces of broken and unused precious metal items buried together with complete ones in the ground. In many cases, contemporary Muslim and Western as well as Eastern European coins, various wire jewellery, and fragments of costume fittings made of precious metals are found together in these hoards. In our presentation, we aim to present the current state of research on hoards in the Carpathian Basin. Currently, six important hoards from the 10th–13th centuries are known in the Carpathian Basin. These are the dirham hoard from Maramureş County, as well as the treasures from Zseny, Nagyarsány, "Királyföld" (Rom. "Pământul Crăiesc"), Darufalva (Aust. Draßburg), and Richárdpuszta. The finds are not only and exclusively silver objects or fragments as the gold hoard from Zseny clearly demonstrates. The presentation wants to bring to the horizon of research again the assemblage unearthed in the 19th century – the hoard of Darufalva/Draßburg, and to highlight what types of connections the 11th century Carpathian Basin had with the regions mentioned. This hoard reveals that they are related to the Rus in Kiev, the finds in modern-day Poland, and comparable artifacts found in the Scandinavian region. We would want to discuss our most recent research on the similarities and wider web of relationships surrounding the Darufalva hoard in our talk.

14 FIGHTERS OR MERCHANTS? CZERMNO/ CHERVEN' ON THE POLISH-RUS' MEDIEVAL BORDER AND OBJECTS RELATED TO COMMERCE

Florkiewicz, Iwona (University of Rzeszów, Institute of Archaeology)

The archaeological complex in Czeremo identifiable with the early medieval stronghold of Cherven' lies in eastern Poland in the middle reaches of the Bug River. The first written reference to this fortified town dates to the armed struggle between Poland and Rus' of the late 10th - early 11th-centuries; the last record in Rus' chronicles appears under the year 6797 (1289). The hillfort site in Czeremo (c. 190 x 120 m) is the focus of the settlement complex (total area, 150 hectares). Archaeological materials excavated on the hillfort date to the 10th-11th century reflect a cultural situation that was still in a state of flux. However, in the 12th-13th centuries Cherven' was definitely a Rus' city. This is confirmed by written records and the rich assemblage of archaeological objects excavated at Czeremo, some of which display Cyrillic inscriptions.

The results of the excavations (2010-2011 and later seasons) demonstrated the huge research potential of Czeremo and other sites in the Cherven' Towns region. In our presentation we report on an impressive assemblage of finds related to commercial activity, as small lead seals 'type Drohiczyn', fragments of weighing scales, weights and currency bars (grivna).

The presence in the assemblage from Czeremo of numerous devotional objects and magnificent personal ornaments identify the stronghold at Czeremo as a “gateway city” located on the border between two cultural zones, one that connected rather than separated their inhabitants.

15 STICK-SHAPED INGOTS OF THE OLD RUS’: STAGES OF CHANGE

Komar, Oleksii (Institute of Archaeology NASU)

Silver stick-shaped ingots have long been considered one of the main means of payment in Old Rus’ from the 11th till 14th centuries. However, there are very few such finds in the treasures of the time of the Mongol conquest of Rus’ 1237-1240 AD where hexagonal ingots of the “Kyiv type” completely dominate. The length of stick-shaped ingots in this group is always more than 16 cm. An XRF elemental analysis of the metal’s composition shows the similarity of their silver to ingots of the Kyiv type and stick-shaped ingots of the Lithuanian type. The latest of the treasures of this group is a hoard of ingots from Chersonesos, hidden during the events of 1278.

The second group of hoards consists of ingots 14-16 cm long with a higher silver content (98-99 %). The ligature of these ingots does not contain bismuth, which is typical for dirkham and Old Rus’ silver of the 10th-12th centuries. The metal’s composition revealed the Central European origin of the raw silver (except for Czech deposits). This change is most likely related to Novgorod’s treaty with Gothland and German cities in 1270.

Short curved ingots of the “Novgorod type” (length 12-14 cm) are characterized by two-stage casting and often lower silver content in one of the layers. The predominance of lead over copper in the ligature indicates a change in production technology and in silver sources. The deterioration in ingots quality occurred in sync with the decline in silver content of the European coins in the mid-14th century.

Our observations confirm N. Bauer’s opinion about the chronological significance of the length of Old Rus’ian ingots, but they also support the opinion of researchers who distinguish “long” stick-shaped ingots as a separate type. The change of the two types occurred no earlier than the 1340s.

16 PALEOPATHOLOGY OF CONTACT ZONES: MASS GRAVE ON BEREZAN ISLAND

Kozak, Alexandra (Institute of Archaeology, National Academy of Science of Ukraine, Kyiv)

Contact zones in medieval Eastern Europe are studied using archaeological and genetic methods. The morphological and pathological features of the human skeletons may indicate different types of cross-cultural or cross-population contacts.

Located in the Black Sea at the mouths of the Dnipro and Bug rivers, on the route from the Varangians to the Greeks, Berezan island was likely a site of cultural contacts during the Middle Ages. The island has yielded a wealth of archaeological finds, including foundries, Byzantine and Rus’ artifacts dating back to the early 2nd millennium AD, and burials from the same period.

In 2016 a shallow pit with the remains of 45 individuals dating back to the 11th-13th centuries was discovered on the island. Most of the individuals were young males and adolescents over the age of 12. There were ten children aged from three months to 12 years and three females.

The features of the bones and healed injuries suggest that the male individuals were physically active, possibly as warriors.

Perimortem injuries were found on the skulls and postcranial skeletons of 8 -14 of the 45 individuals. The partially healed injuries on the bones suggest that some of the males survived the battle for a few weeks before their deaths. Traces of a periosteal reaction on the limbs, scapulae, and pelvis could indicate pre-mortem torture. The frequency of inflammatory processes’ exacerbations in children and adolescence indicates a sharp decline in living conditions in the weeks preceding death.

The deceased may have been island residents or arrived here on ships sailing along the Dnipro River. The circumstances of their death can be inferred from the two arrowheads found in the grave and probably from the burial features.

1138 THE ANTI-HABI TOOLKIT: 2ND WORKSHOP ON SOLUTIONS AND MEASURES FOR PREVENTING AND ADDRESSING HARASSMENT, ASSAULT, BULLYING AND INTIMIDATION IN ARCHAEOLOGY

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Coltofean-Arizancu, Laura (EAA Education, Training and Professional Development Advisory Committee; EAA Appeal and Anti-Harassment Committee; Archaeology and Gender in Europe (AGE) Community of the EAA) - Gaydarska, Bisserka (Archaeology and Gender in Europe (AGE) Community of the EAA) - Hawkins, Kayt (Institute of Archaeology, University College London) - Hlad, Marta (Vrije Universiteit Brussel)

Session format: EAA Education, Training and Professional Development Advisory Committee

This interactive and collaborative workshop is part of a series of training events through which the European Association of Archaeologists (EAA) aims to provide a safe space for everyone attending its Annual Meetings. It follows up on to the first workshop organized with this scope at the 29th EAA Annual Meeting in Belfast, in 2023. It aims to equip participants with information and practical tools to identify, prevent and address situations of harassment, assault, bullying and intimidation (HABI) in their personal and professional life.

WORKSHOP STRUCTURE

PART 1

- A presentation on the current state of HABI in European archaeology based on the latest research.
- A training by the Active Bystander Training Company (United Kingdom) offering strategies for intervention in hostile situations (e.g. bullying, microaggression, discrimination).
- A training in which participants will learn to practice skills to safely use in HABI contexts both as targets and witnesses.

PART 2

- A presentation on the occurrence of HABI in Italian archaeology by the National Association of Archaeologists in Italy.
- A presentation of the educational package developed by the Swedish Ministry of Education for raising awareness about and preventing HABI by Petra Aldén Rudd, the initiator of the #metoo movement in Swedish archaeology.

PART 3

- A discussion in which participants can ask questions about HABI and share their feedback on the training.

The workshop is organized with the support of the EAA’s Education, Training, and Professional Development Advisory Committee, its Appeal and Anti-Harassment Committee and its Archaeology and Gender in Europe Community, in collaboration with the British Archaeological Job Resource’s RESPECT Campaign and Paye ta Truelle.

We understand individuals, particularly those who have experienced HABI, may wish to step out of the workshop at any point for a short period and a safe space will be made available.

1139 THEM AND US: INTERDISCIPLINARY APPROACHES TO IDENTITY, COMMUNITY, AND 'OTHERNESS' IN THE MEDIEVAL WORLD

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Diana, Annamaria (Independent researcher/Terra Ultra Silvam Archaeology) - Marcu Istrate, Daniela (Institutul de Arheologie ‘V. Parvan’, Bucharest) - Toso, Alice (Bonn Center for ArchaeoSciences (BoCAS), Institut für Archäologie und Kulturanthropologie, Rheinische Friedrich-Wilhelms-Universität)

Session format: Regular session

What is ‘identity’ and what gives an individual the sense of belonging to one human group or another? Is the perception of one’s identity a subjective or an objective matter, and what makes a group of people a ‘minority’? These questions, foundational to the study and understanding of human societies, often recur in archaeological debates but are also somewhat avoided by researchers because of their potentially controversial socio-political and cultural implications.

During the Middle Ages dramatic cultural, religious, political, genetic, and linguistic exchanges among populations across the globe led to the formation of collective identities, in concurrence with the retention, or persecution, of minorities. Such complex, multi-scalar biocultural processes, sometimes reflected, but, more often, not immediately apparent in the archaeological context, are the focus of this interdisciplinary session. We welcome case studies exploring the fascinating phenomenon of identity formation in the medieval period as the result of both conflicting and balancing forces. Advances in archaeological sciences and biomolecular technologies have undoubtedly facilitated the

identification of trends and patterns of cultural and biological diversity. However, today more than ever, cross- and inter-disciplinary cooperation, communication, and the contextual analysis of archaeological and biomolecular data are paramount to successful results.

We seek to bring together scholars, researchers, and professionals who have identified trends and new perspectives in the study of the medieval world through both traditional and ground-breaking approaches to the observation, recording, analysis, and interpretation of the archaeological context. The session will accept contributions investigating the following (but not limited to):

- Multi- and cross- disciplinary approaches to the study of biocultural diversity.
- The coexistence and co-dependency of socio-cultural groups as the result of non-linear power dynamics.
- Processes of identity formation and tools for the detection of pluralities.

ABSTRACTS

1 IDENTITY FROM FUNERARY SITES BETWEEN THE CARPATHIANS AND THE DANUBE IN THE MIDDLE AGES

Magureanu, Andrei (Institute of Archaeology "Vasile Parvan")

The Middle Ages are a very popularised and well-known historical period. The reconstruction of biocultural human identities and their formation in the region embedded between the Carpathian Mountains and the Danube River during this crucial historical period is, however, still at its dawn.

Archaeological academic discourse was based until recently on 1) cultural-historical-based analysis, 2) typo-chronological markers, and 3) on proving the validity/legitimacy of historical sources with archaeological discoveries. Preventive archaeology, however, has allowed researchers to change this picture by bringing to light significant amounts of new evidence with the discovery of important cemeteries, churches, and other funerary sites. Nevertheless, the recovery, analysis, and interpretation of large interdisciplinary datasets from those archaeological sites exceed the frame of a traditional scholarship and require the use of novel methods and techniques. In recent years, for example, anthropological research has increasingly resorted to the use of isotopic analysis, looking for, among others, dietary and migration patterns along with more 'traditional' demographic information.

With this paper, we intend to corroborate known archaeological evidence with data from other disciplines to try to reconstruct different identities between the 14th and the 18th century in the Lower Danube region.

2 BIOCULTURAL ANALYSIS OF THREE MEDIEVAL TRANSYLVANIA BURIALS ASSOCIATED WITH A MILLSTONE

Reinman, Lauren (Western Carolina University) - Zejdlik, Katie (Western Carolina University) - Nyárádi, Zsolt (Haáz Rezső Múzeum)

During the excavation of the Papdomb archaeological site located in Văleni, Romania (Patakfalva), three simultaneously buried individuals were uncovered from beneath a broken millstone within the walls of the church. Multi-person burials are not unusual at the site, however, the association of three adult burials underneath a broken millstone requires additional investigation. The site encompasses the remains of a medieval church and its associated cemetery (11th-18th century). Some 930 burials were recovered from the site. The literature regarding the use of millstones in the burial context is limited and only offers broad generalizations. Here, in contrast, we explore a range of specific possible interpretations, ranging from simple post-depositional movement of the millstone to considerations of the practical and religious importance of millstones through different cultures and time periods. By exploring the multiple meanings, symbolisms, and folklore associated with millstones, this work contributes to the reconstruction of mortuary symbolism from the Papdomb site and approaches to interpreting atypical or unique burial contexts in general.

3 THE ROLE OF THE GRAVE DIGGER: EVIDENCE OF VARIOUS BURIAL PRACTICES IN TRANSYLVANIAN, HUNGARIAN-SZEKLER COMMUNITIES (AD 1050-1800)

Privette, Cameron (Western Carolina University) - Carvalho, Carlos (University of Bradford) - Reinman, Lauren (Western Carolina University) - Zejdlik, Katie (Western Carolina University) - Nyárádi, Zsolt (Haáz Rezső Múzeum)

Parker-Pearson's (1999) oft cited phrase, "the dead do not bury themselves" has led to decades of broad investigation surrounding the created social perception of an individual in different contexts and at different scales (family, military, celebrity). However, little research exists on the last individual to physically place the dead. Gravediggers have an extended relationship with the deceased and the mortuary landscape through initial placement as well as secondary placement

when the initial grave is disturbed, as was common in medieval European cemeteries. This paper discusses the lived experience of gravediggers in medieval Europe through investigation of social expectations, folk accounts of the gravedigger experience, and bioarchaeological evidence of gravedigger actions. The Papdomb archaeological site in Transylvania, Romania (AD 1050-1800) acts as the archaeological case study and includes broad burial types (semi-disturbed graves, ossuary, grave shaft modifications) indicative of gravedigger choice and action. Correspondence analysis was run to compare burial type with age, sex, and location of each individual. The paper explores several possible interpretations ranging from the individual gravedigger's experience to community expectations in an attempt to highlight an important but overlooked step in medieval mortuary practices.

4 BUILDING GRAVES IN A PARTICULAR WAY: THE ANTHROPOMORPHIC CHOICE

Marcu Istrate, Daniela Veronica (Romanian Academy, "Vasile Pârvan" Institute of Archaeology, Bucharest)

This paper will explore a peculiar burial custom practiced by medieval communities of the eastern Carpathian Basin: the use of anthropomorphic graves.

Christian cemeteries, characterized by the uniformity of the ritual and the lack of inventory, rarely open opportunities to socio-culturally differentiate individuals. However, research on the early medieval cemeteries in the eastern Carpathian Basin offers a rare exception to this rule.

In Central-Eastern Europe, the formation of the Christian society was a process completed by 1200, largely with the help of important groups of settlers brought to this region from Western Europe, mainly from the Germanic territories. Starting around the year 1100, these people established settlements in Transylvania, and in the earliest layers of their cemeteries both simple graves with rectangular pits and anthropomorphic graves, dug or built according to the human body shape, have been recorded. The deceased were in most cases placed in the ground, but sometimes in a wooden, brick or stone coffin. Such cases have been recorded only in limited areas of the cemeteries, and completely disappeared around the year 1300. Anthropomorphic graves therefore represent a unique feature, marking a difference in the Christian funerary ritual. It is therefore important to ask, why did some members of the same community choose an anthropomorphic pit instead of a regular one? Was this a sign of a particular status, belief, personal taste, or, on the contrary, an arbitrary choice? There is no answer so far.

The present paper investigates this burial habit observing yet another pattern on several anthropomorphic graves uncovered in the episcopal cemetery from Alba Iulia. Archaeologically and historically interpreted as a multiethnic burial ground, this cemetery is exceptionally rich in inventory, thus providing new clues for the analysis of the identity of those who chose those burial receptacles.

5 TEXTILE TOOLS IN EARLY MEDIEVAL SLAVIC CEMETERIES. A WORKING INSTRUMENT, AN IDENTIFIER OF DIFFERENCE, OR A CLASSIFIER OF CULTURAL IDENTITY

Godlewska, Patrycja (Szkoła Doktorska Nauk Humanistycznych Teologicznych i Artystycznych AAH; Nicolaus Copernicus University in Toruń, EuroWeb)

Socio-cultural identification in archeology is possible when analyzing grave equipment or using biological sciences. The difference or uniqueness of the deceased was often evidenced by the abnormal arrangement of the skeleton or the uniqueness of the grave equipment. But what if the burial looks nothing special at first glance? Is archeology able to comment on excluded people and, for example, sexual minorities? Textile tools (spindle spindles, spindles, needles) are a recurring element in cemeteries around the world and various chronological periods. Culturally, they belong to women, but their presence is also recorded in male burials. Often as the only piece of equipment. Spinning and weaving in Slavic cultural circles had strong symbolic connotations of a midwife, doctor, or queer person who held a special place in society. Spinning and weaving have strong symbolic connotations with the midwife, doctor, or changeling, who held a special place in the community. A man who engaged in this or was forced to do so was perceived as unmanly, effeminate, or homosexual. Evidence can be seen, for example, in the Scandinavian sagas. In neighboring Slavic countries, spinning was seen as an undignified activity and reserved for economically dependent people or slaves. This is especially visible in barbaric law, including: at the Lombards. In this presentation, I will present research results from several selected cemeteries in Poland, from the early Middle Ages, relating them to the European context. Using the knowledge of archaeobotany and mnemonics, I try to explore the possibilities of using archeology in the study of people excluded and marginalized in society. In this case, an element that may indicate differences is the presence of a textile tool in the grave. Its relationship in the funeral space with other elements.

6 HEADS UP FOR IDENTITY: INTEGRATING ANTHROPOLOGICAL AND FORENSIC METHODS FOR THE ANALYSIS OF ISOLATED SKULL REMAINS FROM MEDIEVAL ROMANIAN CEMETERIES

Diana, Annamaria (Independent researcher/Terra Ultra Silvam Archaeology) - Garcia-Donas, Julieta (Centre for Anatomy and Human Identification, School of Science and Engineering, University of Dundee, UK)

Medieval burial grounds and parish cemeteries have provided researchers with the largest skeletal assemblages from any period of human history and are, therefore, a precious tool for wide-scale populations studies. Christian burial grounds generally present similar, predictable patterns, from grave orientation to standardised positioning of the body and ritual placement of personal items with the deceased. Quite often, however, excavators come across isolated (articulated or not) groups of bones, individual bones, or large groups of commingled skeletal remains. Although somewhat overlooked because they offer less demographic information than a complete, articulated burial, isolated and commingled bones are nevertheless evidence of differential burial practices and of the impact of human activities and taphonomic/post depositional events on the preservation of the archaeological context.

Among the anatomical elements of the skeleton, the skull is a key element to gather demographic information, with the facial portion offering insights on the living individual's facial features, proportions, and morphology. Moreover, the cranium is genetically and environmentally affected providing key information about biogeographical origin and sexual dimorphism. This paper presents the results of the anthropological assessment carried out by means of integrated osteological and forensic methods on a selection of crania and skulls from Romanian medieval cemeteries. The materials were singled out and chosen based on condition, morphological and paleopathological observations, and their recovery from unusual or decontextualised locations. The results obtained from this study have shown how the use of multidisciplinary techniques maximises the information obtained from skeletal remains poorly documented archaeologically and helps reconstructing the identity of otherwise 'forgotten' individuals, commonly lost in the piles of commingled remains in archaeological skeletal collections.

7 REGIONALISM, RURALITY, DYNAMICS AND FOODWAYS: EXPLORING TRANSITION AND IDENTITY THROUGH AN INTERDISCIPLINARY STUDY OF 3RD-8TH CENTURY NORTHAMPTONSHIRE

Ortega González, Alvaro Felipe (University of Leicester)

To understand the period of transition between Late Antiquity and the Early Middle Ages in Britain, scholars have proposed various models that attempt to explain the processes that gave rise to later medieval institutions and ultimately the multicultural origins of the English people. The academic debate that surrounds this contentious period has mostly formed its core either on the concept of ethnicity or emphasizing the economic collapse of the Western Roman Empire with singular models of causation proposed. Moreover, a metanarrative underlies the debate, which has been formed by ideas and perspectives that are based on sources that were written later than the period discussed. This has led many researchers to reproduce gaps of interpretation, and no matter how much information is involved, the source of the problem comes from its philosophical foundation.

In this paper I suggest looking for alternative explanations that go away from singular causation models that (usually) base their arguments in binary concepts of population dynamics. For this, I propose an approach that explores identity not only by using as a premise 'migration' but also the concepts of 'rurality', 'regionalization', and 'diet'. Moreover, I would like to stress the role of interdisciplinarity, philosophy and bioarchaeological perspectives to obtain a clearer image of the role of this transition.

A detailed bioarchaeological analysis of closely related rural settlements promises to provide information on an overlooked part of society, yet one potentially far more indicative of how this transformative period was experienced on the ground. For this presentation I will do an introduction to my PhD case study: the population of the middle Nene Valley, Northamptonshire, between the 3rd and the 7th centuries AD through an interdisciplinary perspective that joins stable isotope analyses for migration ($\delta^{18}O$, $87Sr/86Sr$, $\delta^{34}S$) and diet ($\delta^{13}C$, $\delta^{15}N$, $\delta^{34}S$) with osteoarchaeology and history.

8 BREASTFEEDING AND WEANING PRACTICES IN THE CARPATHIAN BASIN: A CASE STUDY FROM MEDIEVAL BRAȘOV

Toso, Alice (Bonn Center for ArchaeoScience (BoCAS), University of Bonn) - Diana, Annamaria (Independent researcher) - Marcu Istrate, Daniela (Romanian Academy, "Vasile Pârvan" Institute of Archaeology, Bucharest)

In recent decades, there has been a growing emphasis on the study of the archaeology and anthropology of childhood. Data on medieval populations from the Carpathian basin is, however, still scarce and understanding the dietary practices and nutritional status of non-adult individuals in Transylvania is essential for gaining insights into historical socio-cultural practices in this region. Specifically, the analysis of infant diets aids in reconstructing aspects of daily life among archaeological populations, offering insight into local dietary traditions from a socio-cultural perspective

and variations in childcare across socio-economic contexts. Medical texts detailed best practices for breastfeeding and introducing solid foods, often promoting nursing until the child is two years old.

In order to explore non-adult diets and wellbeing in this area, 20 permanent teeth have been sampled from the Brașov medieval assemblage recovered at St. Mary's church and the isotopic ratios of $\delta^{13}C$ and $\delta^{15}N$ have been measured in serial sections of dentine. Statistical modelling was then applied to calculate the most likely timing and duration of breastfeeding and weaning. Focusing on the following research inquiries, the aim of this paper is therefore twofold: reconstructing the primary diet for non-adults in Brașov, Romania, throughout different time periods; and to identify distinct weaning diet between sexes.

By integrating osteoarchaeological information from each skeleton with isotopic values from their teeth, we have been able to identify and better understand developmental patterns related to biological sex and different time periods, offering the first insight into medieval childrearing practices in Brașov.

9 MARGINALISED COMMUNITIES IN LATE MEDIEVAL LISBON: A MULTI-ISOTOPIC DIET AND MOBILITY STUDY OF THE RUA DAS LAGARES 74 NECROPOLISES

MacRoberts, Rebecca (Hercules Laboratory and IN2PAST, Universidade de Évora, Évora, Portugal) - Evangelista, Lucy (Era Arqueologia, S. A., Lisbon, Portugal; Interdisciplinary Center for Archaeology and Evolution of Human Behaviour (ICArEHB), University of Algarve, Faro, Portugal; Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra, Coimbra, Portugal) - Lourenço, Marina (Centre for Functional Ecology, Laboratory of Forensic Anthropology, Department of Life Sciences, University of Coimbra, Coimbra, Portugal; Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra, Coimbra, Portugal; Era Arqueologia, S. A., Lisbon, Portugal) - Barrocas Dias, Cristina (School of Technology Sciences, Department of Chemistry and Biochemistry, University of Évora, Évora, Portugal) - Vasconcelos Vilar, Herminia (Escola de Ciências Sociais - CIDEHUS, University of Évora, Évora, Portugal) - Schöne, Bernd (Institute of Geosciences, University of Mainz, Mainz, Germany) - Maurer, Anne-France (Hercules Laboratory and IN2PAST, Universidade de Évora, Évora, Portugal)

The site of Rua das Lagares 74 in Lisbon, Portugal, contained evidence of the non-continuous use of the space for the burial of at least two different Late Medieval communities/religious groups, likely to have been cultural and/or ethnic minorities. The earlier necropolis (I), which consisted of burials belonging to an apparent Jewish/Christian/'New' Christian cult, was abandoned and vandalised before the end of the 15th century, coinciding with the expulsion of Jewish communities from Portugal in 1497. Following a period of dereliction, the cemetery was again used for burials adhering to Islamic traditions (necropolis II) in the end of the 15th/early 16th century. Anthropological assessments of the skeletons have suggested that many individuals buried in necropolis II were exceptionally tall and had some osteological features consistent with African origins, generating the hypothesis that some of these individuals may have belonged to a Wolof community – a Senegambian ethnic group that arrived in Portugal during 16th century colonial expansion. In this study, multi-isotope analysis has been applied to skeletal material from necropolis I (30 individuals) and necropolis II (23 individuals) in order to elucidate dietary and mobility patterns between and within these communities. Our key considerations include: "What can dietary patterns, revealed through stable isotope analysis (C, N, S), infer about cultural/communal food choices as well as access to nutritional resources for minority groups in 15th/16th century Lisbon? and "What can mobility indicators (S, O, Sr) tell us about the locality/non-locality of the individuals, buried in necropolis I and necropolis II, who may have existed on the fringes of Christian society in Late Medieval/Early Modern Lisbon?"

10 FOOD AND GRAVE GOODS: EXPLORING COMMUNITY AND OTHERNESS IN EARLY MEDIEVAL IBERIA

García-Collado, Maite (University of the Basque Country (UPV/EHU))

Grave goods in Medieval cemeteries have often been used as an element of identity construction and, thus, material evidence of belonging to a certain community. But in Early Medieval Iberia (5th-10th c. CE) their distribution is very strongly determined by regional differences, being absent from large areas where community identities must have been expressed in alternative ways. This presentation will explore the potential and limitations of diet as inferred by carbon and nitrogen stable isotope ratios to infer collective identities, with an emphasis on the meaning of homogeneity and diversity of dietary patterns. We will reflect on the relationship between food and grave goods and the complementary role of these two proxies in the performance of social status and exclusion through examples from the Basque Country and central Iberia, where the relatively high frequency of grave goods constitutes a good laboratory to test these hypotheses. Later we will extrapolate the conclusions to other geographic contexts where grave goods and other material indicators of collective identities are less common in order to test if diet can be an effective proxy in the definition of past community membership.

1140 HEALTH AND DISEASE IN MEDIEVAL ISLAMIC POPULATIONS IN EUROPE

Session theme: 6. The Mediterranean from Within

Session organisers: Gijón, Ramón (Universidad de Granada) - Sarr-Marroco, Bilal (Universidad de Granada) - Gómez-Martínez, Susana (Universidade de Évora) - Jiménez-Brobeil, Sylvia (Universidad de Granada)

Session format: Regular session

The European Mediterranean coast was an area of Islamic expansion in the Middle Ages, which generated population mobility, socio-economic changes and the introduction of novel crops, establishing new contacts between East and West.

This rapid process of conflict, resilience and adaptation brought about changes in lifestyle, health and disease linked to the population influx and the impact of the new religion in transforming individual and social customs and behaviour.

The study of medieval European Islamic societies has been enriched by the adoption of bioarchaeological approaches, including molecular biology, palaeopathology, stable isotope study, paleoparasitology, carpology, archaeozoology, and climatology, among others. These complement traditional studies based on written sources and the material culture of the period.

The purpose of this session is to bring together different researchers for an update on their latest findings from a multidisciplinary and international perspective. Discussion will focus on Islamic populations in medieval Europe, based on general studies, case studies and methodological research in diverse geographical locations.

ABSTRACTS

1 ISLAMIZATION AND CHANGING HYGIENIC CONDITIONS IN THE WESTERN MEDITERRANEAN (7TH-15TH CENTURIES): THEORY, PRAXIS AND EVIDENCE IN THE ARCHAEOLOGICAL RECORD

Sarr-Marroco, Bilal (University of Granada) - Piñero Palacios, Juan Manuel (University of Granada)

"Al-naẓāfa min al-īmām", cleanliness is proper to faith. With these words (hadith ḍaʿīf attributed to the prophet Muhammad) summarizes the spirit that imbues Islam since its advent. Water, rituals, hygiene are part of the Islamic regulations, of the civic and rural norms, but also of the religious dogma. The Muslim man and woman must imperatively go to prayer in a state of purity, ritual and hygienic purity that can only be achieved with a washing that can be minor (al-wuḍūʿ) or minor (al-gusūl) depending on the degree of impurity.

In this paper, we intend to analyze those elements of Islamic regulation (law, norms and archaeological evidence) that affect both the individual and the collective and that impose changes in behavior with respect to hygiene treatment, consumption, time management, etc. The expulsion of polluting activities, the obligation to maintain minimum hygiene measures, to take care of one's appearance. In theory, all this has a theoretical impact on a lower incidence of the spread of contagious diseases, presence of bacteria and parasites that pass into the intestines of individuals and that biomedicine has been studying. The Islamization entails the respect of these norms, the influence of the Islamic communities on the other dominated ones as well as the appearance or multiplication of constructions (ḥammām) or of new objects for the care and the personal hygiene.

2 MÁGREG AL-AQṢÀ AND AL-ÁNDALUS: A SHARED HISTORY OF CLIMATE, FAMINE AND EPIDEMICS

Patarnello, Claudia (Instituto de Estudios Medievales y Renacentistas, y Humanidades Digitales (IEMYRhd); Universidad de Salamanca)

The links between the Maghreb al-Aqṣà and al-Andalus have been a constant throughout the centuries. And if they are approached from the perspective of palaeoclimatology, there is no exception. In this communication, the main objective will be to reconstruct those climatic anomalies, mainly droughts and storms, which have been detected in the texts of the chroniclers Ibn Abī Zarʿ and Ibn ʿIdārī during the time span defined as the "Medieval Warm Period", or rather "Medieval climatic anomaly", which dates from around the 10th-14th centuries. The direct consequences of a year of bad harvests or storms that destroy crop fields due to climatic fluctuations are basically twofold: periods of famine, and an increase in the price of grain, considered the main food of sustenance throughout the Islamic West. Thus, these consequences are also evident in the Arabic texts that provide data for both al-Andalus and the Maghreb al-Aqṣà. In this way, the relevance of climate in the historical-geographical analysis of a territory becomes visible. In addition to other factors usually considered relevant (political, religious, etc.), climatology had a very direct influence on the daily life of the population, and even on the political decisions of the rulers or dynasties, all of whom were subject to natural conditions and a physical environment beyond their control.

3 MALARIA IN AL-ANDALUS: FROM WRITTEN MEDICAL SOURCES TO A PROPOSAL FOR A PALAEOPARASITOLOGICAL STUDY

Duras, Salvatore (Università degli studi di Sassari) - López-Gijón, Ramón (Universidad de Granada)

Malaria is a parasitic disease caused by protozoa of the genus Plasmodium that is transmitted by the bite of the female mosquito Anopheles sp. It is notable for its high morbidity and mortality and its importance throughout human history.

References to this parasitosis can be traced back to ancient sources, especially in medical writings of different cultures. In the case of al-Andalus, thanks to the development of medicine, influenced by Greco-Latin and Oriental written sources, the presence of malaria can be inferred from the symptomatology in populations of the Iberian Peninsula.

This contribution proposes a journey through the possible attributions of malaria in medical texts from al-Andalus, as well as an innovative proposal for a palaeoparasitological study in areas prone to the discovery of this parasite in this cultural horizon, using the latest advances made in science to identify the presence of malaria from the skeletal remains of past populations.

4 HEALTH AND HYGIENE IN AL-ANDALUS. CONSIDERATIONS ON A PRIVATE BATH IN MÉRTOLA (PORTUGAL)

Palma, Maria de (Campo Arqueológico de Mértola; CEAACP/Centro de Estudos em Arqueologia, Artes e Ciências do património) - Martínez, Susana (Universidade de Évora; Campo Arqueológico de Mértola) - Fernandes, Marco (Campo Arqueológico de Mértola) - Rodrigues, Clara (Campo Arqueológico de Mértola) - Lopes, Virgílio (Campo Arqueológico de Mértola) - Rafael, Lígia (Câmara Municipal de Mértola)

In the Islamic world, bathing is a part of the rituals in the Koranic principles for purifying the body and spirit. Certain acts are considered impure and require ablutions. These are particularly needed before prayer in the mosque. Nevertheless, personal hygiene is also connected with its therapeutic virtues, following the greco-roman traditions, with Hippocrates as the most notorious exponent. Ever since Late Antiquity, people knew that some waters had particular healing powers. There were known and explored thermal springs, which, in some cases, led to the coining of the names of places such as Alhama in Spain and Alfama in Portugal.

Throughout Late Antiquity in the Iberian Peninsula, the collective bathing infrastructures (thermae) were abandoned, and it is impossible to determine if bathing was maintained as a private habit.

The discovery of baths (ḥammāmāt) from the twelfth century onwards in al-Andalus can be considered evidence of the recuperation of these hygienic practices. The discovery of a small private bath in a reasonably humble home on the slope of the Castle of Mértola is a study case for the personal hygiene habits in the small cities of Garb al-Andalus.

5 DIGGING IN THE PAST OF MEDIEVAL ISLAMIC POPULATION IN AL-ÁNDALUS. THE NECROPOLIS OF SAHL BEN MALIK (GRANADA, SPAIN)

Fernández Romero, Pablo (Universidad de Granada) - Suliman, Amjad (Independent archaeologist) - Ruiz Román, Francisco (Universidad de Granada) - López-Gijón, Ramón (Universidad de Granada)

The necropolis of Sahl ben Malik or of Bab Ilvira, with a chronology that spans from the 11th century to the 15th century AD, it is considered to be the main cemetery in Granada during the Nasrid period.

Given the importance of this necropolis, it is referenced by various authors, both contemporary and later. But, despite have been an object of study since de Early Modern period, it's because of the legal regulations developed during the last quarter of the XX century and thanks to the development of the Archaeology, that a great number of archaeological interventions have been carried out, providing us with a huge amount of new data, essential to take an approach to the ways of living and death in the muslim population of medieval Granada.

However, and in spite of several attempts, until nowadays it hasn't been made a synthesis that groups all these works and allow us a global vision of it. For that reason, it's presented a synthesis with the purpose of comprehend the reality of this period, from a multidisciplinary point of view, with the archaeology, history and geography as central axis, as well as with the geology and physical anthropology, focusing in the main cemetery of the medieval Granada.

6 OSTEOARCHEOLOGICAL STUDY OF A DIMMÍ FUNERAL SPACE IN MADINAT ILBIRA (MEDINA ELVIRA, GRANADA)

Piñero, Juan (University of Granada) - Sarr, Bilal (University of Granada)

The set of data that we present below comes from a space with a funerary nature that was found in 2008 during the course of an archaeological activity at the Medina Elvira site (Granada). The ritual arrangement shown by both the graves and the buried, placed in a supine position, added to the recent radiocarbon analysis of the remains, has allowed us to infer that this cemetery area was in use by an apparently non-Islamized sector of the population. Consequently,

this fact has provided valuable information for current studies that seek to address religious survival and resistance, whether Jewish or Christian, in al-Andalus contexts that have been Islamized since the 8th century. Furthermore, in conjunction with the above, the possibility of studying the bone remains from an anthropological perspective has allowed an approach to the physical characteristics of this dhimmi population that, during at least the 11th century, lived within the urban space of the historic city from Madinat Ilbira.

7 MUSLIM BURIALS IN NIMES : ELEMENTS OF HEALTH IN EARLY MEDIEVAL ISLAMIC POPULATIONS IN GAUL ?

Gleize, Yves (INRAP - National Institute for Preventive Archaeological Research) - Mion, Leia (Cardiff University) - Mendisco, Fanny (CNRS) - Deguilloux, Marie-France (University of Bordeaux) - Blunt, Sierra (IN) - Breuil, Jean-Yves (INRAP - National Institute for Preventive Archaeological Research)

Muslim burials excavated in Nimes (France, 8th c.) are the earliest Muslim graves discovered north of the Pyrenees. The three tombs identified, containing male subjects, are the only evidence to date of the presence of groups with Arab-Berber origin on the northern margins of the Islamic empire. Their study therefore constitutes a unique opportunity to document the biological features of these very specific populations of the early Middle Ages. New analyses (funded by the Fyssen foundation) were therefore conducted to complete our knowledge of the origin, lifestyle and health of these exceptional individuals. Paleogenomic analyses were first completed to identify the geographic origin of the male subjects. Then the combined analyses of classical palaeopathological markers (trauma and oral paleopathology), stable isotopes, microbial DNA from dental calculus and pathogen DNA were conducted to investigate the health and diet of these individuals. The new acquired data will be compared as far as possible with local populations while considering the difficulty of working with small samples. Finally, these results will be discussed in a broader historical approach to clarify whether they can provide data on Islamic populations in this part of Europe during the Early Middle Ages.

8 CRANIAL AND DENTAL NON-METRIC TRAITS FROM NORTH AFRICAN POPULATION IN AL-ANDALUS

Mena-Sánchez, Luis Alberto (University of Granada) - Maroto Benavides, Rosa (University of Granada) - Jiménez Brobeil, Sylvia (University of Granada)

The Islamic expansion in the Middle Ages produced human population mobility to Europe. In this sense, the arrival of new genetic groups from Africa to the Iberian Peninsula produces the implementation of changes in the lifestyle, health, and disease, linked to the new form of life of their cultural groups.

The bioarchaeological approach allows for new tools to enrich our knowledge about the Islamic groups in Al-Andalus, including the analysis of big data with new computer programs.

In this paper, we present a database analysis of Cranial and Dental non-metric traits of 400 Argaric (1900-1600 B.C.) and Medieval (XII-S.XIV c.) skeletal remains from the South of the Iberian Peninsula.

We apply MMD formulas that have allowed us to diverge between variables.

The programming language R and the statistical package AnthroMMD were used for the correct formulation.

These results show that other ethnic groups of the North African population exported cranial and dental non-metric traits to the population in the medieval period of the Kingdom of Granada in the 12th and 15th centuries in Al-Andalus.

9 TRAUMATIC INJURIES IN MEDIEVAL SILVES (SOUTHERN PORTUGAL): A BIOCULTURAL PERSPECTIVE

Gonzalez-Ruiz, Ana (Universidade de Coimbra; Centro de Investigação em Antropologia e Saúde (CIAS)) - Santos, Ana Luisa (Universidade de Coimbra; Centro de Investigação em Antropologia e Saúde (CIAS)) - Gonçalves, Maria José (Museu Municipal de Arqueologia de Silves)

The analysis of frequency and type of trauma in skeletal remains can provide information about interpersonal violence and the risks of daily life faced by the people who occupied different realms of society.

This work aims to explore how the people of medieval Silves experienced their lives by contrasting the evidence of bone trauma and exploring their possible linkage to battles taking place at that time. For this purpose, 51 individuals from an Islamic necropolis (9th-13th century) and 82 individuals buried in a Christian necropolis (13th-onwards) were examined. All the individuals are above 12 years old. The macroscopic and, when necessary, radiological analysis revealed similar frequencies of fractures: 12% (6/51) in Islamic and 18% (15/82) in Christians. However, the distribution of injuries by sex and age differs. In the first group, the fractures were all in adult males while in the Christian ten males and three females (one young and two adults) shown fractures. In addition to these individuals, three unsexed

Islamic adults and two Christians also presented fractures. Multiple fractures (ulna and ribs in one case and ulna and metacarpal in the other) were only found in two Christian individuals.

Individuals from the Islamic necropolis presented all different traumatic lesions varying from a nose fracture, fractures to the ribs, ulna, metacarpals or fibula. Rib fractures were the most common among the Christian sample, followed by ulnar, metacarpal, and humeral fractures. Interpersonal violence could have been the cause of certain fractures, either isolated (like the nasal fracture) or combined (like the ulnar fractures with the metacarpal or rib fractures). Most fractures seemed well-aligned and infection-free, suggesting possible medical treatment.

10 PALEODIET IN THE NASRID KINGDOM OF GRANADA: URBAN VS. RURAL POPULATIONS

Jiménez-Brobeil, Sylvia A. (University of Granada, Spain) - Martín-Alonso, José Francisco (Universidad de Granada) - Maroto Benavides, Rosa María (Universidad de Granada)

The Nasrid Kingdom is framed between the 13th and 15th centuries AD and was the last Muslim territory in the Iberian Peninsula. The aim of this work is to check if there are differences in the diet between urban and rural inhabitants from analysis of stable isotopes in bone collagen. We also want to find out if there are differences by sex that can be deduced distinctions by gender. We have analyzed 50 samples of individuals buried in the cemeteries of the cities of Granada and Baza and about 90 from the rural farms of La Torrecilla and Talará and we have obtained their isotopic values of $\delta^{13}C$ and $\delta^{15}N$. The $\delta^{13}C$ values show differences between cities and countryside with a higher consumption of C4 plants in the rural populations. The $\delta^{15}N$ values, however, are similar, although in the city of Granada they are lower than those found in other urban contexts of al-Andalus. The only differences by sex point to a higher consumption of C4 plants among urban women, which may indicate gender differences in access to certain foods.

11 CONCEALED ROLES. A PALAEOANTHROPOLOGICAL READING ON NOURISHMENT, HEALTH, AND CARE GIVING IN A PEASANT COMMUNITY IN THE SHARQ AL-ANDALUS

Negre, Joan (RomanIslam Center - Universität Hamburg) - García, Marcos (Universidad de Granada) - Sancho, Sheyla (Independent Researcher)

The Andalusi farmstead of Xaresa (Xeresa, Valencia) is one of the most thoroughly excavated rural sites of the period. As part of the urban development of the area, archaeological work has been carried out on a number of plots around the site. This revealed several houses, a small pottery workshop, a water wheel and a maqbara with around 200 inhumations. An initial study of this burial site has recently been undertaken on the basis of a random sample of 35 skeletal remains, which allowed a preliminary paleoanthropological study and several genetic profiles of this community. In addition, samples were taken from all individuals and fauna at this and other nearby sites for comparative carbon and nitrogen stable isotope analysis in bone collagen.

Thanks to these approaches, it is now possible to present a detailed health assessment of this peasant community. The objective is twofold in nature. On the one hand, to analyse various factors relevant to understanding the well-being of these people. These include their demographic profile, their diseases and pathologies, the markers of occupational stress or the quality of their diet, among others. On the other hand, to study the gender dimension and the roles of age in this community with regard to daily activities, which include family and community sustenance and welfare. In this sense, we are interested in the crucial role played by these activities in regulating social life and forging relational bonds in this rural settlement, which remained populated from the second half of the 10th century until the Christian conquest in 1239.

12 ZONOTIC PARASITE INFECTION FROM OSTEOARCHAEOLOGICAL RECORD IN AL-ANDALUS

Gijón, Ramón (Universidad de Granada) - Duras, Salvatore (Universidad de Granada) - Benavides, Rosa (Universidad de Granada) - Mena Sánchez, Luis (Universidad de Granada) - Camarós, Edgard (University of Santiago de Compostela) - Jiménez Brobeil, Sylvia (Universidad de Granada)

Certain parasitosis can be identified from the osteoarchaeological record, such as the case of *Echinococcus granulosus*, a zoonotic parasite that allows us to relate the existing interactions between man and canids, as a result of the reproductive cycle of the parasite (from canids to herbivores/man as an intermediate host), linked to agro-pastoral communities throughout history.

In this paper, we present the finding of two fragmented calcified formations associated with two individuals from medieval Islamic cemeteries in the Kingdom of Granada in al-Andalus, dated between the 12th and 15th centuries A.D. For their correct attribution, macroscopy, scanning electron microscopy and energy dispersive X-ray spectroscopy studies were carried out. These results were used in the subsequent differential diagnosis, showing that the calcifications are hydatid cysts caused by *E. granulosus*. This finding allows us a bioarchaeological approach to these populations, evidencing human-animal interactions and agropastoral practices in medieval period of the Kingdom of Granada in al-Andalus.

1144 NEW TRENDS IN MEDIEVAL AND MODERN GLASS: GLASS CENTRES, PRODUCTION AND TRADE

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: De Juan, Jorge (Departamento de Prehistoria, Historia Antigua y Arqueología, Universidad Complutense de Madrid, Spain.); UNIARQ – Centre for Archaeology, School of Arts and Humanities, University of Lisbon, Portugal.) - Occari, Veronica (University College London, Institute of Archaeology, United Kingdom.) - Pactat, Inès (Université de Toulouse, Laboratoire TRACES, UMR 5608, France.) - Almenar, Luis (Departamento de Historia de América y Medieval y Ciencias Historiográficas, Universidad Complutense de Madrid, Spain.) - Capellà, Miquel Àngel (Departament de Ciències Històriques i Teoria de les Arts, Universitat de les Illes Balears, Spain.)

Session format: Session with precirculated papers

Over the past two decades, there have been noteworthy breakthroughs in the study of glass materials. These advancements enable recognition of long-distance exchange networks that go beyond the transfer of finished products like beads, vessels, mosaic tesserae, but also encompass raw materials, technological knowledge, shapes and decorations in glass working.

The aim of this session is to provide a forum to explore from a multidisciplinary approach the various aspects of recent medieval and modern glass research, encompassing glass centres, production, raw materials, trade routes, emerging applications, technological advancements, and evolving aesthetic preferences. The session will include pre-circulated papers that facilitate attendees to thoroughly engage with each presentation, fostering in-depth discussions during the EAA meeting. The discussions and findings of this seminar aim to make a significant contribution to the field, fostering collaborative synergies among researchers from diverse countries.

When investigating glass, it is crucial to acknowledge its widespread distribution over extended geographical areas and periods of time. Here, we will welcome submissions exploring this topic, regardless of geographical boundaries (Europe, Africa, Asia, América, Oceania), and covering a broad chronological spectrum that spans both the Middle Ages and the Modern era. After the congress, and a review process, the accepted papers will be published in both physical and digital formats (open access).

ABSTRACTS

1 TRACES OF ROMAN GLASS IN EARLY ISLAMIC PRODUCTION IN NORTH AFRICA

Kaviani, Kelsi (University College London, Institute of Archaeology, United Kingdom) - Fenwick, Corisande (University College London, Institute of Archaeology, United Kingdom) - Freestone, Ian (University College London, Institute of Archaeology, United Kingdom) - Charlton, Michael (University College London, Institute of Archaeology, United Kingdom) - Höpken, Constanze (Universität zu Köln, Archäologisches Institut, Germany) - Lepri, Barbara (Independent Researcher) - Chaouali, Moheddine (Institut National du Patrimoine, Tunis, Tunisia) - Fentress, Elizabeth (University College London, Institute of Archaeology, United Kingdom) - Limane, Hassan (Institut National des Sciences de l'Archéologie et du Patrimoine (INSAP), Rabat, Morocco) - von Rummel, Philipp (Deutsches Archäologisches Institut, Germany)

Natron glass, manufactured from sand and Egyptian mineral soda, was the dominant glass type produced and used in the 1st millennium CE until the 8th – 9th centuries when natron flux was displaced by plant ash. Recently published data from Spain and Sicily show plant ash glass in sole production by the 10th century. However, early Islamic North African glass technology is not well documented, and the processes around the natron-plant ash transition are unclear. This paper presents laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) data on early medieval glass from the site of Walīla (Roman Volubilis) in northern Morocco and the sites of Chimtou, Bulla Regia, and Sabra al-Mansūriya in northern Tunisia. An abundance of recycled Roman and late antique natron glass was found in the 8th – mid-9th century Walīla assemblage, although the presence of glass of the Bet Eli'ezer type suggests that fresh Levantine natron glass was reaching the site into the 8th century. Lead oxide at 2-12% in virtually all glass recovered from Walīla suggests that attempts were made to extend the available glass reservoir as far as possible. Plant ash compositions dominated the 10th – 11th century Tunisian glass, but antimony above background levels in over two-thirds of the glass highlights the presence of Roman glass and the continuity of recycling practices within North Africa beyond the transition from natron to plant ash glass. These results suggest that while freshly made glass was available in early Islamic North Africa, demand was such that a range of strategies were adopted to extend the available material. This paper concludes by providing a first in-depth look at the technological choices of glass workshops in North Africa and their relationship to the circulation of glass in the early medieval Mediterranean.

2 GLASS MANUFACTURE IN THE CAPITAL OF THE AL-ANDALUS CALIPHATE. NEW ARCHAEOLOGICAL EVIDENCES

Velo-Gala, Almudena (NOVA University of Lisbon) - Vilarigues, Márcia (NOVA University of Lisbon)

In recent years, research carried out by different international teams has demonstrated the importance of glassware consumption for the economic and social development of the Andalus population. Cordoba, capital of the Caliphate of al-Andalus, has been a site of great interest for the study of such productions and craftsmanship, primarily for two reasons: its significance as a centre of power at the time of the greatest splendour of the Islamic occupation of the Iberian Peninsula, and its exceptional archaeological context. Despite this, glass manufacture evidences have been, until now, scarce. However, in the absence of structures identified with glass furnaces, there are other remains that indicate the presence of this type of activity in the places near where they are documented. This is evidenced in this work, which presents the results of the study of a set of glasses related to this craft activity: crucibles, molten glass, manufacturing remains and production failures. All of them were documented during archaeological interventions that have been taking place since the beginning of the 21st century in the western part of the current urban centre, as a consequence of significant urban growth.

These materials indicate the possible existence of a glassmaking centre in the large north western suburb, a space traditionally associated with a population linked to the economic-administrative management of the nearby city of Madinat al-Zahra.

3 THE FLUX AND FLOW OF ISLAMIC GLASS BANGLES: FINDING FROM THE PRODUCTION SITE OF KAWD AM-SAILA IN YEMEN (C.14TH-16TH CENTURY)

Nash-Pye, Charlotte (University of Kent; British Museum) - Meek, Andrew (British Museum) - Schibille, Nadine (CNRS Orleans) - Simpson, St John (British Museum) - Richards, Liam (University College London) - Charlton, Mike (University College London)

Islamic glass bangles of the medieval to Ottoman periods are found in wide distribution across the Islamic world. Yet, when compared with glass vessels or beads, relatively little is known. Nonetheless, their unique chemical compositions may unlock wide distribution patterns, offering insights into trade, cultural transfer and Islamic female identity during these understudied periods. Combining traditional archaeological approaches with modern archaeochemical techniques has revealed new manufacturing techniques, typological styles and unique glass signatures. This has indicated likely origins, trade, trends, and other cultural insights regarding the periods and places of production during the medieval-early modern periods.

This paper presents key compositional results and typological distinctions for glass bangles produced at the known Yemeni workshop of Kawd am-Saila in Aden, currently in the Middle East Department of the British Museum. With the aid of esteemed colleagues world-wide, typological and archaeochemical (SEM-EDX and LA-ICP-MS) analysis was undertaken at the British Museum, CNRS Orleans and UCL Institute of Archaeology, producing exciting results. It discusses the typological and geochemical characteristics of the Yemeni bangles and their identification amongst other glass bangle collections studied. Analysis of the glass bangle collection from Somalia in the Africa, Oceania and the Americas Department at the British Museum reveals an aligning geochemical signature, as the initial typological assessment suggested. Therefore, it is now scientifically verified that such fragments were exported not only to the Persian Gulf but also into the Horn of Africa (HoA).

This research has opened a promising new field of potential research into the trade of Islamic glass bangles from the Middle East into east Africa and more specifically between the Aden region of Yemen and the HoA. Although only in its infancy, it is hoped that the success of this approach will encourage further future cross disciplined research into the dissemination of Islamic glass bangles.

4 LEAD GLASS AT THE TOP OF EUROPEAN CHURCHES IN THE HIGH MIDDLE AGES. ORIGIN AND DISTRIBUTION OF AN UNUSUAL PRODUCTION

Pactat, Inès (Université de Toulouse, Laboratoire TRACES (UMR 5608)) - Gratuze, Bernard (CNRS/IRAMAT (UMR 7065))

During rescue excavations in 2012 on the Place du Château in Strasbourg (France), which is bordered by the cathedral and the Palais Royan, a collection of stained glass windows was discovered in levels dating from the 11th to 19th centuries. Most of them date from different phases of the medieval cathedral's construction. Seven of these flat glasses are dark green, sometimes with grisaille, and are characterised by a wood-ash lead composition (13 to 37% PbO). Isotope analyses showed that the lead ore certainly originated from the Harz massif in Germany. This discovery provided the opportunity to investigate the distribution of these wood-ash lead glasses in Europe between the 11th and 13th centuries, from Iceland to Finland and from France to Austria. Although the glass workshops are not known, these artefacts testify to an original form of production that was limited to the Harz region, where a

number of fire crafts were located during the High Middle Ages. We therefore propose to explore the links between the development of silver metallurgy and glassmaking in order to understand how this unusual glass recipe was used. The elemental and isotopic compositions of this lead glass also allow us to consider its widespread use to decorate the major religious buildings, highlighting a connected medieval society.

5 **MEDIEVAL AND MODERN BLUE NOTES. COBALT BLUE GLASS FROM CENTRAL-WESTERN FRANCE : ARCHAEOLOGICAL AND ARCHAEOMETRIC PERSPECTIVES (13TH-18TH CENTURIES)**

Buisson, Mathilde (Université d'Orléans - IRAMAT (UMR 7065)) - Gratuze, Bernard (IRAMAT (UMR 7065))

"Cobalt oxide imparts to vitreous compositions a beautiful, very intense blue colour, which is very resistant to the most violent fires. It is widely used in glassmaking." This remark by Georges Bontemps (1799-1883) also applies to earlier centuries. Indeed, archaeological data show a concentration of medieval and modern cobalt blue glass among the finds from central-western France. Previous studies have shown that different ores were used to colour blue glass over the long term. In this corpus of consumption sites, we find a wide range of forms in archaeological contexts dating from the 13th to the mid-18th centuries. The colouring agent has been identified in both stained glass and tableware, and in the case of tableware, both in the base glass and in the decoration (enamels, fillets...).

Here we present the results of archaeometric analyses of cobalt blue samples and how they fit into the dynamics of the use of this pigment. As well as studying the raw materials used to make the objects, we will look at the technical aspects of how they were shaped by the glassmaker. Analyses sometimes reveal recycling practices. The archaeological context in which the glass was found will be considered, stimulating reflection on its function, the glassmaker's craft and trade flows in an area that is still little studied in terms of the archaeology and archaeometry of glass.

6 **THE CONTRIBUTION OF EXPERIMENTAL ARCHAEOLOGY AND ARCHAEOMETRY TO THE UNDERSTANDING OF EARLY MEDIEVAL GLASS RECIPES**

Van Ham-Meert, Alicia (CReA-Patrimoine, Université libre de Bruxelles, Avenue F.D. Roosevelt, 50 . CP 133/01, 1050 Bruxelles; 4MAT, Université libre de Bruxelles, Avenue F.D. Roosevelt, 50 . CP 165/63, 1050 Bruxelles) - Kail, Nathan (4MAT, Université libre de Bruxelles, Avenue F.D. Roosevelt, 50 . CP 165/63, 1050 Bruxelles) - Blary, François (CReA-Patrimoine, Université libre de Bruxelles, Avenue F.D. Roosevelt, 50 . CP 133/01, 1050 Bruxelles) - Bussienne, Géraldine (KIK-IRPA, 1 Parc du Cinquantenaire, 1000 Bruxelles) - Delplancke, Marie-Paule (4MAT, Université libre de Bruxelles, Avenue F.D. Roosevelt, 50 . CP 165/63, 1050 Bruxelles) - Lecocq, Isabelle (KIK-IRPA, 1 Parc du Cinquantenaire, 1000 Bruxelles) - Wouters, Helena (KIK-IRPA, 1 Parc du Cinquantenaire, 1000 Bruxelles) - Neuray, Brigitte (SPW, AWaP (Agence Wallone du Patrimoine), Direction opérationnelle Zone Est – Service de l'Archéologie, rue Montagne Sainte-Walburge 2, 4000 Liège, Belgium)

During the excavations of the Stavelot abbey large amounts of glass were recovered from various dates in different contexts. One corpus dating from before 881 is particularly interesting as it contains both natron glass and early wood ash glass. Thus, providing a unique window into the period where both recipes overlapped and wood ash glass recipes were developed and spread. The elemental analysis of the glass revealed a broad range of compositions, not entirely unexpected for a possible "experimental" phase (Van Wersch et al. 2014). Further elemental and isotopic analysis evidenced a higher-than-usual concentration in rare earth elements (Van Ham-Meert et al. 2021). These observations led us to investigate the possibility of local production, using local raw materials. This paper discusses the results of experimental trials of glassmaking using local bracken and wood to produce ash, and using local sand and quartz as silica source. The raw materials and the final glass were characterized in the same way as the original glass. Preliminary results show that the sands from local rivers are inappropriate for glass making due to their high concentration in aluminosilicates. The effect of plant maturity on ash composition was also evidenced, which might, in part, explain the high variability in the medieval glass pieces. Further elemental and isotopic analysis of the synthesized glass will help in further answering the question of provenance.

7 **THE GLASS CENTRES PROJECT: DISCOVERING THE IBERIAN GLASS TRADE NETWORKS OF THE LATE MEDIEVAL AND EARLY MODERN ERA**

De Juan, Jorge (Universidad Complutense de Madrid; Universidad de Lisboa)

The GLASS CENTRES project, funded by the European H2020 program under the Marie Skłodowska-Curie actions, delves into the exploration of glass production and trade networks in the Iberian Peninsula from the 14th to the 16th century. This study aims to fill a significant gap in our understanding of the Iberian glass industry, which played a crucial role in global-scale trade. Despite its historical and economic significance, the knowledge of late medieval and early modern Iberian glass remains limited, with scant archaeological, typological studies, and chemical analyses conducted.

The project integrates analytical techniques, typological studies, archaeological records, and textual sources to provide a comprehensive understanding of the characteristics of Iberian glass production and its evolution over time. Given the geological diversity of the Iberian Peninsula, a central hypothesis of the project is that the chemical composition of the glass will reflect the variability of the geological substrates of the different glass centres.

To validate this hypothesis, glass samples, along with associated raw materials, have been collected from archaeological sites and workshops from the principal production areas identified in historical texts. These samples have been chemically analysed with Portable X-Ray Fluorescence (p-XRF) and Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS) to ascertain their distinct properties and facilitate differentiation among the different productive regions.

Results from the GLASS CENTRES project reveals complex patterns of glass production, trade, and consumption, highlighting transregional connections and the significance of Iberian glass in the context of global trade networks. These findings not only enrich our understanding of European cultural and technological heritage but also lay the groundwork for future research on commercial interconnections between Europe, the Atlantic, and the Americas. Furthermore, the insights gained from this project will facilitate the accurate identification of Iberian-origin materials and collections currently dispersed across museums worldwide.

8 **GLASSMAKING IN THE KINGDOM OF VALENCIA. EMERGENCE, DEVELOPMENT, AND CONSOLIDATION OF A LATE MEDIEVAL CONSUMER INDUSTRY IN EASTERN IBERIA (C.1278-C.1500)**

Almenar Fernández, Luis (Universidad Complutense de Madrid)

This paper assembles recent evidence coming from a variety of monographic analysis undertaken in the last years on the glass industry in the late medieval kingdom of Valencia. A combination of sources (municipal, judicial, notarial, and tax records) is considered alongside recent published material evidence excavated in both rural and urban areas of the realm. This all leads us to pose three chronological phases in the history of the Valencian glass industry in the Later Middle Ages: Phase 1 ('Emergence'), characterised by the settlement of Christian glassmakers from Catalonia after the conquest of the Islamic taifa of Balansiya and the opening of glass furnaces; Phase 2 ('Development') consisted of the proliferation of these workers and the first regulation of the trade by municipal and royal institutions. Glass productions implied then mostly luxury products, which coexisted with glass imports from outside the kingdom; Phase 3 ('Consolidation') implied a rapid boom of this economic activity, when living standards of the population had increased and the demand for non-luxury glass pieces had exponentially grown. A Valencian luxury glass production was also important enough by then to supply collections in royal courts around Iberia. Functional, non-aesthetic or feeding-related glass typologies were also in the ascendance, as a result of new pharmaceutical knowledge, resulting in a professional demand coming from medical professionals. Altogether, this in-depth diachronic analysis is set within the scenario of European glass industries of the period, arguing that the Valencian case, alongside the nearby examples of Palma de Majorca and Barcelona, reveal the dynamism of this growing trade in the late medieval Mediterranean, which took off centuries earlier than the early modern glass development of the North of Europe.

9 **FROM WORKSHOP TO TABLE : 14TH CENTURY GLASSWARE IN THE NORTH-WEST MEDITERRANEAN, AN INVESTIGATION BASED ON THE NORTH CATALAN EXAMPLE**

Mach, Jordi (Université de Paris 8 Vincennes Saint-Denis; Laboratoire d'Archéologie Médiévale et Moderne en Méditerranée (Aix-en-Provence))

Hollow glass dating from the 14th century collected from consumption sites in northern Catalonia is part of the formal models typical of the "southern" productions defined by D. Foy and now well attested from Provence to the Balearic Islands and from Midi Toulousain to Franche-Comté. Aesthetically, these vessels are characterized by the use of two main categories of decorative techniques, sometimes combined. Blowing the pieces into molds create honeycombs or ribbed patterns on the walls. The use of colored glass, mainly dark blue, but also opaque white and red, allows the production of polychrome pieces. In the archaeological contexts of this period, in Roussillon and Ampurdan, two

types of glass appear almost systematically in the find assemblages and testify to these two aesthetic categories: bottles with mold-blown honeycombs decoration and bowls with concave rims decorated with blue trails. In this paper, I will propose an initial survey of the spatial distribution of finds of these two forms throughout the north-western Mediterranean. These areas of distribution, combined with the mapping of the workshops that produced the forms and with textual and archaeometric data, enable us to delineate technical territories within which manufacturers and skills circulated just as much as the glass already produced and marketed. Finally, I will return to the North Catalan situation to question the particular place of these two types of glass within archaeological assemblages. In the light of the region's written and iconographic sources, the ways in which this tableware was consumed seem to have been linked to the service of wine. The meeting and exchange with other specialists present at this session will enable us to discuss these initial results and envisage collective investigations to be carried out, including on other glass types and other territories.

10 THE GRALLA WORKSHOP: NEW EVIDENCE OF GLASS PRODUCTION IN 18TH CENTURY MALLORCA

Capella, Miquel Angel (Universitat de les Illes Balears) - Serra, Neus (Universitat de les Illes Balears) - Merino, Josep (Archaeologist)

The glass manufacturing in Palma de Mallorca is documented, both archaeologically and through written records, since the first third of the 14th century. Unfortunately, only material remains of a single workshop corresponding to the second half of the 17th century have been located. In this contribution, we present the study of the material remains of the glass kiln of the Gralla family established in Palma in the mid-18th century. These glassmakers, who arrived from Catalonia, were active in this location until the late 19th century. Thanks to written documentation, some of their activities to obtain raw materials are known, such as the soda coming from the nearby island of Cabrera, as well as some orders. The archaeological remains of the two kilns that appeared during the excavation process and other elements excavated on the site where they were located are analyzed.

In addition, the study of the recovered ceramics is presented, allowing for an approximate dating of the workshop's activity, the crucibles, and the glass remains from the last production of the kiln, probably from the late 19th century. Although it is a kiln of small dimensions, it provides information about the active structures in Palma and the island's construction tradition, which will be compared with that of other European workshops of the same chronology.

11 THE TECHNOLOGY OF MEDIEVAL VENETIAN GLASS AND THE LEVANTINE CONNECTION

Occari, Veronica (UCL) - Freestone, Ian (UCL) - Fenwick, Corisande (UCL) - Silvestri, Alberta (University of Padua) - Marcante, Alessandra (Independent Researcher) - Schibille, Nadine (CNRS-IRAMAT) - Barfod, Gry (Aarhus University)

The present paper seeks to understand the development of the medieval glassmaking industry in Venice, investigating the technological practices, the raw materials procurement, and the connection with the Levant. Major, trace element and isotopic data are presented for 181 glass samples from Venice and from the sites of Cividale, Asolo and Padova (12th -15th century). Other glass assemblages have been analysed for comparisons, including the famous Aldrevandin beakers and Mamluk enamelled vessels. The results identified the presence of six main compositional groups, consistent mainly with the use of different types of silica sources, which were both sourced in Italy and imported from the Levant, while Levantine plant ash as flux was consistently employed and was probably sourced in different regions in the Levant. Importantly, the largest group of glasses presents a distinctive trace element composition and provides the first compositional fingerprints for medieval Venetian glass made with pebbles from the Ticino River, which can be used to distinguish it from the technologically similar Islamic glass.

12 GLASSES FROM SAN FRUTTUOSO ABBEY OF CAPODIMONTE (CAMOGLI, GE): ARCHAEOLOGICAL AND ARCHAOMETRIC DATA

Bagnasco, Marta (Università degli studi di Genova) - Benente, Fabrizio (Università degli Studi di Genova) - Riccardi, Maria Pia (Università degli Studi di Pavia) - Campana, Nadia (Soprintendenza Archeologia Belle Arti e Paesaggio per la città metropolitana di Genova e la provincia di La Spezia)

The San Fruttuoso Abbey of Capodimonte complex (Camogli, GE), located in an inlet on the southern front of the Portofino promontory, was excavated for the first time in the 1980s, thanks to restorations promoted by the Fondo per l'Ambiente Italiano. The research, coordinated by the

Soprintendenze Archeologica e per i Beni Ambientali e Architettonici della Liguria, aimed at outlining precisely the life phases of the abbey. In landfill layers (Area D, 13th/late 14th century) tableware artifacts were found, such as a pottery kit showing notable contacts with Tyrrhenian

Italy and the Mediterranean, but also glasses and vitreous bottles. Furthermore, numerous fragments of glass lamps of the church's lighting equipment were found while archaeologists were digging the abbey and the complex liturgical rooms.

The intervention will focus on glass finds analysis, thanks to the multidisciplinary approach and the dialogue between archaeological and archaeometric data. The goal is to outline the main features of the table equipment and the living conditions of the medieval monastic community of San Fruttuoso. The San Fruttuoso glasses, typologically studied, will be analysed in electronic microanalysis and in LAM ICP MS to evaluate their compositional variability and possible chemical/geochemical comparisons, for verifying the use of local products and materials or

imports (of the finished objects or of the raw materials). Through the study of the table and the lighting equipment, therefore, we will attempt to clarify which were the commercial contacts and the economic power of the monastic community of San Fruttuoso.

13 RECENT RESEARCH ON UNIPARTITE LOW COUNTRIES' STAINED-GLASS PANELS FROM THE 15TH-17TH CENTURIES

Patin, Mathilde (Department of Applied Physics and Photonics, Brussels Photonics (B-PHOT), Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium) - Caen, Joost (Em. Professor of the Universiteit Antwerpen, and stained-glass expert, Hertendreef 6, 2900 Schoten, Belgium) - Lecocq, Isabelle (Royal Institute for Cultural Heritage (KIK-IRPA), Jubelpark 1, Parc du Cinquantenaire 1, 1000 Brussels, Belgium) - NYS, Karin (Department of Art Sciences and Archaeology, AMGC Research Group, Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium) - Thienpont, Hugo (Department of Applied Physics and Photonics, Brussels Photonics (B-PHOT), Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium) - Meulebroeck, Wendy (Department of Applied Physics and Photonics, Brussels Photonics (B-PHOT), Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels, Belgium)

Thanks to their position on early modern trade axes, the Low Countries benefitted from preferential access to window glass sheets coming from Northern France and the Rhineland region. Hence to the trade position and the wealth of the cities during the 15th and 16th centuries, the region became the main production centre of stained glass in Northern Europe.

Technical, visual, and artistic study of stained windows can be complemented by analytical investigation to answer questions of dating and authenticity. The combined application of portable X-ray fluorescence spectroscopy (p-XRF) and UV-Vis-NIR absorption spectroscopy allows the screening of a large set of glass panes in a short period. On the one hand, our previous research focused on distinguishing different glass types, including Roman soda-, industrial soda, K-rich glass, and Ca-glass. On the other hand, we explored the identification of the optical signatures to discern two High Lime-Low Alkali (HLLA or Ca-rich) glass subgroups in link with the dating.

This presentation will focus on the analytical results obtained for more than a hundred silver-stained panels from the Low Countries dating from the 15th to the 17th century. As a reference for further studies, we investigated objects belonging to the stained-glass collections of the Royal Museums of Art and History (Brussels), the Museum Aan de Stroom | Vleeshuis Collection (Antwerp), and the J.M.A. Caen private collection (Schoten).

The collaboration among researchers from diverse disciplines allows us to put in relation technical and artistic observations with analytical results. Thanks to the non-destructive analysis, we were able to make new hypotheses on the dating, authenticity, and provenance of the window panels. The results obtained are not only significant for the objects themselves but also contribute to the increase of our understanding of (stained-)glass production in the Low Countries.

1146 DISCOVERING THE ARCHAEOLOGISTS OF EUROPE, 10 YEARS LATER

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Pintucci, Alessandro (Confederazione Italiana Archeologi) - Almánsa Sanchez, Jaime (INCIP-IT-CSIC) - Gransard-Desmond, Jean-Olivier (Arkeotopia) - Scherzler, Diane (DGUF)

Session format: Round table (without formal abstracts)

In recent years, the long wake of the economic crisis that began in 2008, the consequences of Brexit and finally the Covid-19 pandemic have changed European archaeologies enormously: this is a sensation that any observer can relate to in any European country; In many cases, recent statistical data is missing and the last organic research on the working conditions of European archaeologists, on a continental scale, dates back to 2014, 10 years ago.

How archaeologists work in 2023? Where do they work? Who are they? How many of them are working now? These are only some of the questions asked by journalists, politicians or any other stakeholder involved in archaeologists work.

During this round-table discussion, the speakers will present their research carried out in recent years on the activity of archaeological research, and their advice for a new project on a European scale. With this session, we will try to compose an exhaustive picture of what is currently available on the topic and relaunching the urgency and need for new research at a continental level.

1147 **MEDITERRANEAN INTERACTION ?FROM WITHIN?: ISLAND AND COASTAL COMMUNITIES IN DIALOGUE**

Session theme: 6. The Mediterranean from Within

Session organisers: Galmes Alba, Alejandra (INCIPIIT - CSIC; ArqueoUIB research group, University of the Balearic Islands) - Dawson, Helen (Università di Bologna) - Calvo-Trias, Manuel (ArqueoUIB research group, University of the Balearic Islands) - Marino, Sara (Sapienza University of Rome) - Quondam, Francesco (Universität Wien)

Session format: Regular session

Recent advances in scientific methods have highlighted the extent of cultural interaction among island and coastal communities at a global scale and challenged long-held notions of islands as isolated cultural laboratories. Interaction has been increasingly traced from inland and coastal communities to smaller islands, indicating how connectivity networks reflect multiple expressions of identity. The current shift towards connectivity should encourage us to understand these networks in a new way, one that considers the active agency of coastal and island communities in the establishment and development of networks directed inland as well as towards the sea.

In this session, we seek to explore how changes in connectivity relate to identity, material culture, and practices over time and to discuss how the interplay between islands, coastal, and inland communities provides the opportunity to explore issues of cultural integration as well as phenomena of localism and resilience. From network analysis to landscape studies, through pottery, metalwork or nautical data, our goal is to understand how different scales and rhythms of connectivity are reflected in the archaeological record. We hope to open up a dialogue across a range of perspectives in the study of connectivity drawing on different theoretical and methodological approaches. Disciplinary, chronological, and geographical boundaries are deliberately avoided to generate discussions that widen our understanding of cultural interaction in the Mediterranean and beyond.

ABSTRACTS

1 **MATERIAL INTERCONNECTEDNESS IN AN ARCHIPELAGIC MARITIME LANDSCAPE: THE INNER IONIAN SEA ARCHIPELAGO**

Papoulia, Christina (University of Crete)

Bordered by larger islands and situated at a short distance from the mainland, the Inner Ionian Sea Archipelago consists of several land capsules inextricably connected to their neighbouring landmasses. Studying the isles and islets of such an enclosed archipelago offers a unique opportunity to investigate the diachronic interactions between land and sea of the different prehistoric communities that left material traces. This talk presents the research questions, methods and preliminary results of an investigation into the maritime cultural interactions and interconnectedness in a geographic area often regarded as 'peripheral'. It offers new data from cave and open-air sites and tackles upon the fluid boundaries between land and sea in order to explore aspects of connectivity and isolation based on material proxies. This work stems from the 2-year research project "Routes, tools and sea-vessels. A multi-proxy reconstruction of the reciprocally transformative relationship between Stone Age communities and the sea – SeaROOTS" funded by the Hellenic Foundation for Research and Innovation - H.F.R.I. (project number 7186).

2 **LONG-TERM OCCUPATION AND INTERACTION DYNAMICS IN THE CHANNEL ISLANDS: A COMMUNITY-BASED PERSPECTIVE**

Dawson, Helen (University of Tübingen; University of Bologna) - Dettman, Sean (Jersey International Centre of Advanced Studies) - Duval-Gatignol, Hervé (Société Jersiaise) - Pope, Matthew (University College London)

The Channel Islands comprise an archipelago of eight inhabited islands with smaller islets, of different sizes, distances to the mainland, rates of insularisation, and diverging and converging historic trajectories. Understanding how and when the islands were first settled and how their inhabitants adapted to the challenges of island life constitutes a classic case study in island archaeology. In this paper, we provide an overview of the archaeological research we've been carrying out since 2020 on the largest island, Jersey, as part of the Jersey International Centre of Advanced Studies archaeological field school. The results of this diachronic analysis span some 250,000 years of human habitation from the time when Jersey was still attached to mainland to its recolonisation following its gradual insularisation as a result of sea level rise. A key aspect of our work is to understand changes in the degree of isolation and connectivity

as well as the development of "small world networks" and islander identities over time, in dialogue with the island's present-day communities.

3 **BETWEEN ISLANDS, COAST AND INLANDS: RELATION DYNAMICS IN THE MESSINA STRAIT AT THE DAWN OF THE BRONZE AGE**

Marino, Sara (Sapienza University of Rome) - Quondam, Francesco (University of Vienna)

Located at the tip of the Italian peninsula, the area of the Messina Strait represents a privileged context for the analysis of the relationship dynamics between islands, coast and inland areas during Prehistory.

Ever since the Neolithic period, the peculiar geography of this area has favoured the emergence of articulated and multiscale relationships between the mainland and Sicily, radiating as much at the coastal areas as in the innermost sectors of the landscape; the presence of the Aeolian islands, a central junction in the prehistory of the central Mediterranean, inserts another relevant variable into the system, as also reflected in the abundant archaeometric data obtained on obsidian and pottery.

In this communication we intend to focus on the centuries between the end of the 3rd and the early 2nd millennium BCE, a period corresponding to the Italian Early and Middle Bronze Age. Indeed, this period captures a significant evolution in the relationship dynamics between the islands and the mainland, clearly testified to in the archaeological evidence. Though highly integrated, the Early Bronze Age communities of this system show a strong degree of autonomy and local identity. In the Middle Bronze Age, on the contrary, a substantial increase of homogeneity is witnessed; at the same time, however, the archaeological record reveals a certain degree of variability, implying forms of widespread integration as well as cases of localism and/or resilience. The re-examination of some key contexts and the presentation of new Calabrian sites will add new elements to this interesting picture.

4 **APPROACHING THE COAST(S): CROSS-CULTURAL INTERACTIONS BETWEEN CYCLADES AND CRETE DURING THE EARLY BRONZE AGE**

Vrettou, Aikaterini (University of Heidelberg)

During the long period of the Early Bronze Age multiple waves of transcultural interaction were generated in the Southern Aegean, and more specifically between Cyclades and Crete. The intensification of contacts resulted in the transmission of ideas and technologies, along with finished artefacts and raw materials to Crete. The latter should not be regarded as a cultural whole with a uniform material culture, and therefore the influence of the Cyclades on Crete varied significantly spatially, and chronologically as well. Some coastal sites on northern Crete functioned as "gate communities" and undertook the role of transferring imports further and through the various networks established inland on Crete these even reached more isolated sites in the South. While the imported artefacts became gradually integrated in the local codes of communication and practice, at the same time they triggered new ways of production on Crete. In other words, through a selective adoption of the off-island ideas and following the local preferences new forms of various materials were created, bearing similar or new meanings. In this framework through the constant communication between the different regions in the Southern Aegean, a wider space was created which enabled the emergence of new Aegean-wide and local cultural traits and technologies.

5 **ISLANDS FROM WITHIN. CONNECTIVITY STRATEGIES IN THE CONFORMATION OF ISLAND IDENTITIES ACROSS THE BALEARIC ISLANDS (C. 1400-850 BCE)**

Galmes Alba, Alejandra (INCIPIIT, CSIC) - Calvo-Trias, Manuel (ArqueoUIB research group, University of the Balearic Islands)

Did island inhabitants see themselves as such in the past? How did island identities conform and be recognised? From a case study in the Balearic Islands, we aim to reflect on how island identities might have been conformed through interaction, both within and beyond the island itself. With a focus on c.1400-850 BCE we aim to understand the conformation of island identities through two strategies.

First, the series of coastal sites that guided navigation around the island. Connectivity between the islands allowed for the development of a shared habitus, with shared technological praxis and social arenas across them. Secondly, the construction of monumental architecture across the island's allowed for an interconnected landscape within the island, where architecture can be understood as a conveyor for identity. The visual network that the architecture knitted allowed to give meaning and connection to the landscape at an island-level. By combining these two perspectives we aim to reflect on the strategies that island communities used to conform their own identity and recognise themselves as islanders through connectivity.

6 WORKING THE LANDSCAPES: CONNECTING COMMUNITY AND LABOUR IN BRONZE AGE CYPRUS

Gonzalez San Martin, Ana (Brown University)

Island communities in the Mediterranean have long been stereotyped as either intensely syncretic, commercial, and urban-centric in coastal settlements, or as inherently static, subsistence-based, and closed off inland. However, newer approaches in archaeology reveal a more dynamic and complex understanding of community relationality. Within this framework, I propose a labourscape approach as a lens through which to explore the interconnectedness of labour practices, cultural interaction, and connectivity through the landscape.

Focusing on the hinterland of Cyprus, this research delves into the intricate web of community-based decisions and negotiations, challenging traditional notions of rural communities' isolation, "backwardness" and rigid cultural identity. Labor, viewed not just as a utilitarian activity but as a complex social phenomenon, plays a central role in shaping and reflecting the cultural and physical aspects of the landscape. By examining how labour was organized and practiced within Bronze Age communities within the landscape, we can get a sense of how the mobility and interaction were at play in structuring the transmission of practices and technologies.

This approach highlights the active agency of communities in establishing and developing social ties directed both inland and towards the sea. Through the analysis of physical indicators of labour organization, we can expose intricate patterns of labour-based connectivity that facilitated the exchange of knowledge, skills, and resources. By challenging static interpretations of cultural identity and emphasizing the fluidity and adaptability of labour practices, this perspective contributes to a deeper understanding of collaboration, resilience, and the fluidity of identity in the Mediterranean and beyond.

7 BUILDING BRIDGES IN THE CENTRAL MEDITERRANEAN: A SOCIAL AND SPATIAL APPROACH ON BRONZE AGE INTERACTION NETWORKS

Michienzi, Giulia (Università degli studi di Bari Aldo Moro; CNR ISPC)

During the Early Bronze Age, the central Mediterranean saw the rise of insular and coastal centres located at strategic positions along expanding sea routes, as also attested by the growing number of common features in the material record of local communities. Previous research aimed to shed light on the dynamics of a maritime small world including Sicily, the surrounding archipelagos and the Tyrrhenian coast of southern Calabria, starting from the case study of Mursia. This was achieved through the creation of two pottery networks (Social Network Analysis) based on the stylistic motifs from Mursia's pottery repertoire, shared with other sites in the area, which were then exploited as nodes for the creation of a spatial network (Point Proximal Analysis). Although definable as an ego-network, the analysis gave back the reflection of an intricated pattern of influences, geographically widespread on the regional level. A final comparison of the three networks, using the betweenness centrality degree as common parameter, allowed to spot a significant match between the social and the geographic dimensions, with the identification of 17 hypothetical gateway communities. Further research will be developed by widening both the geographical and chronological horizons, analysing interaction networks in an area which also covers both sides of Calabria and the region of Apulia, from EBA to MBA. The choice of elements in the local material record eligible as proxies for economic, social and ideological processes, will lead to the definition of multiple case studies, whose connections will be investigated, once again, through a relational perspective (SNA). Secondly, anchorage opportunities will be evaluated on a GIS by looking at coastal morphology and by calculating their anchorage safety index. The assumed harbours will then be used to build a spatial network balanced through environmental parameters to assess travel duration (Least Coast Analysis combined with PPA).

8 INDIGENOUS IMITATION AND GLOBAL INTERACTION: UNDERSTANDING THE POTTERY OF THE POST-TALAYOTIC, LATE IRON AGE AT TORRE D'EN GALMÉS, MENORCA

Smith, Alexander (SUNY Brockport) - Pérez-Juez, Amalia (Boston University) - Torres Gomariz, Octavio (Universitat d'Alacant) - Patterson, Evelyn (SUNY Brockport)

From approximately 550 to the Roman conquest in 123 B.C.E., the island of Menorca (Spain) was home to a vibrant, Late Iron Age community known as the Post-Talayotic people. As the first millennium B.C.E. bore witness to a dramatic increase in trade, colonialism, and intercultural interaction across the Western Mediterranean, Menorca retained many aspects of its indigenous culture in the face of foreign influence. Nevertheless, certain types of material culture felt the effects of this increased interaction, particularly with Punic and Iberian actors.

Since 2020, the Menorca Archaeological Project has been excavating at the prehistoric site of Torre d'en Galmés. Our excavations have focused on a series of medieval Islamic houses that have excellently preserved the remains of a third century B.C.E., circular domestic structure. From 2021-2023, our excavations have revealed what appears to

be a storage area of the Post-Talayotic house, filled with various examples of pottery, including local indigenous wares and imports.

This assemblage notably exhibits indigenous vessels that are imitations of Punic forms, showcasing a hybrid material cultural practice, but also sustained foreign interaction more generally. What is also clear is a consistent usage of these ceramics for consumption of beverages or libations, in some cases possibly for ritual purposes. At the same time, we have many more indigenous vessels that retain traditional forms and still other imports from Ibiza and North Africa. Nevertheless, these forms serve a different functional purpose from the identified hybrid ceramics.

This paper will discuss the ceramic assemblages discovered by MAP from 2021-2023 in our Post-Talayotic structure, and the ramifications of these hybrid forms for understanding interaction and exchange on the island. Ultimately, we hope to shed light on a dynamic Post-Talayotic Menorca that experienced both cross-cultural interaction as well as indigenous evolution at the end of the Iron Age.

9 TYPOLOGICAL ANALYSIS OF NURAGIC POTTERY FROM CANNATELLO (SICILY): ASSESSING MEDITERRANEAN INTERCONNECTIONS DURING THE LATE BRONZE AGE

Talotta, Natalia (University of Rome "La Sapienza", Italy) - Gulli, Domenica (Soprintendenza BBCCAA, Agrigento, Italy) - Levi, Sara (Hunter College, NY, USA) - Vanzetti, Alessandro (University of Rome "La Sapienza", Italy)

Nuragic pottery is being increasingly recognized in different coastal sites across the Mediterranean during the Late bronze Age, with a specific intensity noted in LHIIIB-III C1. Cannatello (AG) is one of the most relevant sites that contribute to the debate regarding cultural connections and interactions among the major Mediterranean islands during the early phase of the Late Bronze Age. Research at this site has been spearheaded by the Soprintendenza BB.CC. AA of Agrigento, the University of Rome "La Sapienza", and Hunter College of New York. Through the typological analysis of ceramics, evidence of connections have been discerned with Crete, Malta, Cyprus and Sardinia, shedding light on existing relationships between the Western Mediterranean and Eastern Mediterranean. These studies delve into potential themes of transmission and typological/stylistic influences of the ceramics found within the settlement.

Based upon typological analysis of Nuragic pottery from Cannatello, this contribution aims to reconstruct the dissemination patterns of major Nuragic forms and to identify affinities or differences within the involved areas. Notably, there is a prevalence of open shapes, known as conche (currently evidenced in Sicily and Crete) and bowls with interior groove, the latter being attested in all considered sites.

Furthermore, the remarkable concentration of Nuragic-shaped vessel localized in specific areas of the site, the identification of forms produced locally, and the significant typological variability distinguish the site from others located in the eastern area, reinforcing the hypothesis of different types of interaction. Further studies on materials from Cannatello will not only elucidate its significance but also contribute to broadening our understanding of contacts among the major Mediterranean islands during the Bronze Age.

10 ZOOM IN ON CONTINENTAL TYRE: NEW DATA FROM THE LEBANESE-ITALIAN ARCHAEOLOGICAL PROJECT IN TYRE

Haider, May (Lebanese University) - Badawi, Ali (The Directorate General of Antiquities) - D'Andrea, Marta (Sapienza)

This paper will present preliminary data from the Lebanese-Italian Archaeological Project in the Region of Tyre. The project focuses both on archaeological research and cultural heritage protection and promotion in the areas to the east and south of the present-day Tyre peninsula. These regions are represented, respectively, by Tell Mashouk, Shawakeer, and Ras el-Ain. They are traditionally connected with the historical quest for Palaeo-Tyre and must have played an important role in the development of Tyre through the ages; however, little archaeological investigation has been carried out there in the past. Therefore, the Lebanese-Italian Archaeological Project in the Region of Tyre was envisioned to study patterns of human occupation, land and sea use, and water management in this unique maritime cultural landscape in the environs of Tyre. For this ambitious task, a multi-level analytical approach was conceived. The new data, brought by the project, is advancing both our current knowledge of archaeological periods, mainly prehistorical ones, at the Shawakeer and Ras el-Ain areas, while also validating the extraordinary importance of the two areas in understanding the prehistorical periods of the region and the direct role of the continental area in the development of the City of Tyre, the Island. In fact, the study of the regions of Shawakeer and Ras el-Ain provided important insights on the diverse periods with unprecedented discoveries from the Palaeolithic in our project's regions the time when different Homo species used the Levantine corridor to move towards and from Europe. The project was also able to confirm and elaborate previous hypotheses concerning Chalcolithic activities at Ras el-Ain and an Early Bronze Age presence at Shawakeer, and added new information on both areas from the fourth through the second millennium BC. This new data are crucial to reinterrogate patterns of island-coastal interactions in the Tyre area.

11 THE DIFFUSION AND ASSIMILATION OF THE ORNITHOMORPHIC MOTIF AS A CLUE TO THE CULTURAL INTERACTION IN THE PROTOHISTORIC MEDITERRANEAN

Amodio, Francesco (Stadt Zürich)

Regarding the ornithomorphic motif, it has been noted that, with the emergence, from the Middle Bronze Age onwards, of new dominant subjects within much more complex communities capable of spreading particular valuable products, the evidence provided by archaeological sources seems to record a sort of 'democratisation', if compared to the past, in the use of an ideological-religious symbolism originating, as ever, from the cultured areas of the south-eastern Mediterranean and the Near East, in which the ornithomorphic motif, especially that belonging to the Anatidae family, takes hold during the Late Bronze Age and, gradually but increasingly, even more so during the Iron Age. In fact, during the Late Bronze Age there was an epochal turning point in the intensification of cultural contacts and interactions, in which the Mediterranean appeared as a privileged area in which the new protagonists now played a leading role, and in which they spread products and, alongside them, ideas and cultural models often functional to the new socio-economic structures created in many European areas during this phase, which were then assimilated and reworked in a sort of ante litteram orientalisising process.

In its first phase, this took place in some areas of the Italian peninsula thanks to the increasing contacts between the indigenous and the Aegean world, and, in a second phase, thanks to the formation of a metallurgical koinè that united these two worlds within the Mediterranean, taking on the flavour of a revival of pre-existing cultural contents in contrast with the strongly elitist character inherent in the many manifestations documented in previous eras, opening thereby the path to a reciprocity of exchange between the peoples involved.

12 SAINTS' DEDICATIONS AND EARLY MEDIEVAL CROSS-MARKED STONES ON THE WEST COAST OF SCOTLAND

Kurzenkova, Alla (School of Humanities, University of Glasgow)

The West Coast of Scotland encompasses a diverse range set of early medieval cross-marked stones, with topographical settings, different types of stones, and chronologically distributed forms of crosses.

This paper results from the project funded by the British Academy's Researchers-at-Risk Scheme to investigate Early Medieval Cross-marked Stones on the West Coast of Scotland.

An essential basis for the cross form analysis in this paper has been provided by the redating of previously unrecorded cross type similarities on the West Coast of Scotland with other comparative crosses from volumes of the British Academy's Corpus of Anglo-Saxon Stone Sculpture series and the Corpus of Early Medieval Inscribed Stones and Stone Sculpture in Wales. Identifying links to the founders of the sites through dedications to Saints and datable cross type material brought together a picture of the importance of these sites, which developed differently between the 6th and 10th century AD.

Crucially, this configured an understanding of the links between cross forms and Saints, arguing that crosses either coexisted with Saints or were added to a site already made famous by a Saint.

13 ISLANDS OF TRANSFORMATION: INTERDISCIPLINARY PERSPECTIVES ON ADAPTION, RESILIENCE, AND SUSTAINABILITY

Scholten, Thomas (University of Tübingen) - Dawson, Helen (University of Tübingen) - Diaz-Zorita Bonilla, Marta (University of Tübingen) - Dierksmeier, Laura (University of Tübingen) - Rothenburg, Daniel (University of Konstanz) - Schön, Frerich (University of Tübingen)

This paper presents the preliminary results of a new joint project, "Islands of Transformation: An Interdisciplinary Study of Adaptation, Resilience, and Sustainability", hosted by the University of Tübingen (2024-2026). Our aim is to study the dynamics of human adaptation to socio-environmental change in past island societies on a global scale and to understand their strategies of resilience and sustainability. The regions under study comprise islands in the following regions: 1) Mediterranean (Aeolian Islands, Ustica, Pantelleria, Linosa; the Balearic Islands), 2) Southern Pacific (Vanuatu, New Caledonia, Tasmania and Bass Strait islands), 3) Eastern Atlantic (Channel Islands, Canary Islands) and Caribbean (Cuba, Haiti). Our work draws on geoarchaeological, bioarchaeological, archaeological, and historical archives to explore issues relating to colonisation, adaptation, resources, diet, exchange, and transmission of ideas and knowledge. The main goal of this project is to study islands within a global comparative framework and to investigate island communities and their cultural interaction. Through a collaboration between archaeologists, historians, and natural scientists with a broad geographic and chronological range, we challenge established and western-centric perspectives on entangled human-nature transformations in island archaeology and island studies more broadly.

1148 ON THE LIFE OF VOWS: MONASTIC ARCHEOLOGY AND BIOARCHAEOLOGY

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Janeš, Andrej (Croatian Conservation Institute, Department for Archaeology, Kožarska 5, 10000 Zagreb, Croatia,) - Šarkić, Nataša (Aita Bioarchaeology, Caporal Fradera 17, piso 02, Magrat del Mar 11060 (Barcelona), Spain,)

Session format: Regular session

Monasteries from the Early Christian to the Early Modern period held a special place in the Christian world. They represented the realization of the greatest virtues, both for those who wanted to live a good Christian life and for those who wanted to secure a place for themselves in the afterlife. The popularity of monastic life in the period from the 4th to the 18th century is confirmed by the large number of religious communities that arose in Europe. The high status of monasteries was often shown through architectural forms, with monasteries setting trends in different building styles.

This high status of some monasteries can be visible not only in written records, but also through remains of material goods of everyday commodities, from exotic food and drinks to luxury objects used to consume them. In addition, monastic spaces appealed to all the social strata of medieval and post-medieval societies as final resting places. Before the creation of hospitals, as we know them today, the care and treatment of elderly, disabled and sick was provided primarily in monasteries.

We invite papers discussing the visibility of different social groups interacting in various monastic environments, through analysis of everyday objects, foodstuff, architectural development, burial practices, osteological and botanical remains, and spatial organization of monastic complexes and estates.

ABSTRACTS

1 INSIGHTS INTO LIFESTYLE AND STATE OF HEALTH AMONG FRIARS AND LAY PEOPLE BURIED AT THE SANTA CATERINA FRIARY (BARCELONA, SPAIN)

Rissech, Carme (Rovira i Virgili University) - Sanz, Andrea (University of Barcelona) - Falcó, Andreu (University of Barcelona) - Cevallos, Antony (Rovira i Virgili University) - Trujillo, José (University of Barcelona) - García, Mireia (University of Barcelona) - Lloveras, Lluís (University of Barcelona)

Santa Caterina was one of the most important friaries in Barcelona (Spain) during the Medieval and post-Medieval periods (1243 to 1836). The community belonged to the Dominican Order, enabling both friars and lay people to be buried there. The aim of this study is to provide information on the lifestyle and state of health of the individuals buried in this friary, through bioanthropological analysis. We analysed a total of 36 funerary units located in the cloister courtyard (13th c.), cloister gallery (13th-15th c.), chapels inside and outside the church (13th-16th c.) and in the area outside the church behind the apse (13th-14th c.). Results indicate 8 males from the cloister courtyard; 8 males, 6 females, 3 indeterminates and 7 immatures from the cloister gallery; 39 males, 18 females and 33 immatures from the chapels, and 8 males, 6 females, 3 indeterminates and 3 immatures from outside the church behind the apse. The oldest females and males were in the cloister. In contrast, only young male and female adults were found in the other areas analysed. In the cloister gallery, immatures were always above the age of 8 years while outside the cloister immatures were above 0.5 year of age. The musculoskeletal markers and pathologies point to greater physical activity in the individuals from the cloister gallery, particularly in females. Results suggest that the group interred in the cloister correspond to monastic and lay people closely related to the friary. In contrast, individuals interred in the church and outside the church represented a lay cohort able to afford burial there. The highest social class lay individuals were buried inside the church (the higher their social status, the closer to the high altar), well-off people were interred in the chapels outside the church and less well-off people behind the apse.

2 LATE MEDIEVAL LIME BURIALS FROM THE FRANCISCAN MONASTERY IN SCHAFFHAUSEN, SWITZERLAND

Alterauge, Amelie (Department of Archaeology, Cantonal Heritage Service Schaffhausen) - Christen, Linda (Department of Archaeology, Cantonal Heritage Service Schaffhausen) - Haas, Cordula (Institute of Forensic Medicine, University of Zurich) - Lehn, Christine (Institute of Forensic Medicine, LMU Munich) - Schotsmans, Eline M.J. (Centre for Archaeological Science, University of Wollongong; PACEA-UMR 5199, University of Bordeaux) - Schäppi, Katharina (Department of Archaeology, Cantonal Heritage Service Schaffhausen)

The use of lime in burials and mass graves is a well-known phenomenon all over Europe, ranging from prehistory to modern times. It climaxed in the early modern period when burials congested the churches and encountered hygienic reasoning and sanitary control measures. Next to hygienic reasons, several other intentions are ascribed to this practice, such as to accelerate or impede the decomposition, to suppress decomposition odour and limit the spread

of bacteria. However, systematic research on this burial practice in the past is limited, with a few exceptions from forensic experimental studies.

Recent excavations in the church of the Franciscan monastery (c. 1250-1529 AD) of Schaffhausen (Switzerland) have revealed 27 burials in the church's perimeter, comprising single, double and multiple burials, as well as plain earth and coffin burials. The graves are believed to be those of noble and middle-class townspeople who hoped for prayers and salvation in the bosom of the Franciscan convent. According to stratigraphy and radiocarbon dating, the burials date predominantly to the 14th and 15th centuries AD. In 10 cases, the bodies have been treated with varying amounts of a white substance. Physico-chemical analyses characterized these white residues as lime. It was applied over the body in a liquid state or as a powder. Occasionally, the lime had created a cast over the deceased mirroring the body's shape, including imprints of clothing. It was not possible to differentiate whether they used hydrated lime or quicklime. The skeletons underwent a thorough anthropological examination, including morphology, paleopathology, stable isotope and DNA analysis in order to determine the composition, kinship relations and dietary status of the population.

The aim of this paper is to extend the corpus of lime burials in medieval churches for a better understanding of the intentions and chronological and geographical distribution of this burial practice.

3 **NON FUI, FUI, NON SUM, NON CURO: EXAMPLE OF ATYPICAL BURIAL PRACTICE FROM THE RAŠAŠKA - RAČEŠA (CROATIA), 13TH-16TH CENTURY**

Sarkic, Natasa (Aita Bioarchaeology) - Cighetti, Roberto (Aita Bioarchaeology; Osteoarc) - Schendzielorz, Sofie-Kristin (University of Dundee) - Mihaljevic, Marija (Nova Gradiska Town Museum)

The treatment of the deceased is a common practice across all human societies. Burial is a combination of social norms and how the deceased is perceived by those performing the burial. Atypical funerals may indicate that the deceased was considered a "deviant social person". To better understand this phenomenon, we must consider both funerary archaeology, which involves understanding typical burial practices in a given population and how the individual deviates from them, as well as bioarchaeology, which helps determine whether biological factors played a role in the deviation.

During an excavation, a grave numbered 157 was uncovered next to the southern wall of a church, in a layer below the floor. The individual buried there was positioned in an unusual manner, which caught the attention of the researchers. Upon further analysis, it was found that the individual had multiple injuries, some old and some fresh, which were caused by interpersonal violence.

Historical sources indicate that the property where the grave was found belonged to the Knights Hospitallers, who were primarily responsible for providing medical care. This may explain why the individual was buried there. However, it is still unclear why an intervention was performed on the body after death.

4 **POVERTY IN THE BONES. BIOARCHAEOLOGICAL STUDY OF MONASTIC LIFE IN THE COLLEGE DE MÍNIMOS OF ALCALÁ DE HENARES (MADRID, SPAIN)**

Hernández-Fernández, Judith (University of Alcalá) - Gallego-García, Mar (University of Alcalá) - Sánchez-Andrés, Ángeles (University of Alcalá)

The research carried out in the former College of "Mínimos de Santa Ana" (Alcalá de Henares, Madrid, Spain), has provided relevant information on the social and dietary characteristics of a group of religious between 16th and 19th century. The archaeological intervention carried out in 2007 focused on one of the lesser-known convent spaces: the "de profundis" room, a sacred space before the entrance to the refectory. The excavation documented a multi-layered burial space without a pre-established layout. The skeletal remains recovered correspond to sixteen individuals. Their study is providing valuable anthropological information, which together with the archaeological context has helped to better understand a community about which traditionally little information is available, as is the case of the Order of Minims. The first results suggest living conditions marked by significant food shortages, which may even have occurred as early as infancy. All this suggests that a significant part of the convent population was assembled from social contexts in which malnutrition and poverty could be two significant indicators.

5 **WHAT CAN NUNS TELL US? ARCHAEOLOGICAL AND ANTHROPOLOGICAL DATA REGARDING THE VĂRATEC MONASTERY CEMETERY (EASTERN ROMANIA)**

Diaconu, Vasile (Neamț National Museum Complex) - Simalcsik, Angela ("Olga Necrasov" Centre for Anthropological Research, Romanian Academy – Iași Branch, Romania; "Orheiul Vechi" Cultural-Natural Reserve, Republic of Moldova; Institute of Bioarchaeological and Ethnocultural Research, Chișinău, Republic of Moldova)

The Văratec Monastery was founded in the second part of the 18th century, and in the 19th century it became the largest community of nuns in Romania.

Located at the foot of the Eastern Carpathians, the monastery comprises three distinct churches: one built in the late 18th century and two more built in the mid-19th century.

In 2021, during the rehabilitation works of one of the churches dedicated to St. John (1844), preventive archaeological research was carried out, leading to the discovery of 72 burial complexes, accounting for burial graves and reburials, attributed to the late 18th-century and the first half of the 19th century. When the church was built, some of the old graves were moved to different areas of the cemetery, thus explaining the numerous reburials. The degree of preservation is different from one grave to another; some funerary complexes have well-preserved wooden funerary furniture. Given the monastic nature of the cemetery, the inventory is scarce (i.e., only four coins, two wooden crosses, and clothing accessories). A specific element for the graves of nuns is the engraved bricks placed next to the deceased. A few tombstones were also discovered.

Thus far, the burial space at the Văratec Monastery is the only cemetery of a community of nuns researched in Eastern Romania.

The anthropological analysis of the osteological material discovered in the Văratec cemetery, which belongs to a somewhat isolated community from a demographical perspective, provided exciting information consistent with the general anthropological picture of the late medieval and modern periods. On the skeletons, belonging especially to adults, was determinate numerous skeletal abnormalities and pathologies, reflecting this population segment's health status and occupational profile.

6 **THE ROLE OF MEAT IN THE DIET OF THE NUNS FROM THE CONVENT OF SANTA MARIA DE JERUSALEM (BARCELONA, SPAIN)**

Lloveras, Lluís (University of Barcelona) - Falcó, Andreu (University of Barcelona) - Mondejar, Oriol (University of Barcelona) - Nadal, Jordi (University of Barcelona)

The convent of Santa Maria de Jerusalem was located in the Raval neighbourhood in the center of Barcelona (Spain). It was founded in 1462 and was occupied by the Poor Clare Order, the female branch of the Order of St. Francis. The archaeological works conducted at the convent during 2005-2006 allowed the recovery of abundant waste deposits containing a large amount of faunal remains. In this paper we present the results obtained in the analysis of faunal assemblages recovered from two rubbish dumps dated between 15th and 17th centuries. Our aims are to provide new data on diet in monastic houses in Barcelona and to find out the importance of meat in the diet of the Poor Clares community of the convent.

Results indicate a low variety of taxa, being mammals the best represented and particularly caprines (mostly sheep, *Ovis aries*) followed at a distance by pigs (*Sus domesticus*) and cattle (*Bos taurus*). The age at death profile indicate that most animals were immature, slaughtered at the optimum point to provide a maximum meat yield. The parts of the skeleton found indicate a selection of the meaty portions. The avian taxa variety is also low and the domestic fowl (*Gallus gallus domesticus*) clearly dominate the assemblage. The age at death profile data suggest that chickens were preferably consumed.

Finally, our data is contrasted with the background provided by zooarchaeological studies conducted in other contemporaneous monastic houses from Barcelona.

7 **MEDIEVAL MONASTERIES AS ECONOMIC POWERHOUSES: INSIGHTS FROM NUMISMATIC EVIDENCE**

Štefan, Luka (Moneterra - the Money Museum of the Croatian National Bank)

This research examines the economic importance of medieval monasteries during the high and late medieval periods, spanning from around 1100 to 1500. It utilises numismatic data to determine the extent to which these monasteries acted as economic catalysts in their particular regions. The study centres on the examination of coins found in specific locations, namely the Dominican Monastery and the Church of St. Margaret in Gorjani, Croatia. These sites yielded a significant number of medieval coins, primarily of lower value and denominations. Comparable observations are obtained from discoveries made at the remains of the Pauline Monastery of the Blessed Virgin Mary (Bela Crkva) and the Benedictine Abbey of St. Michael the Archangel in Rudina. The presence of coins from external mints or other regions, states, and territories suggests that these religious institutions played a role in enabling wider economic connections and cultural interactions.

The study utilises a methodology that combines the analysis of coins with the assessment of historical sources, such as charters, financial statements, and contemporaneous narratives. This approach allows for the reconstruction of the economic environment in which these monasteries functioned over the specified time frame. The primary emphasis lies on the distribution and use of low-value coins inside these monastic communities, showcasing their intricate participation in regional and maybe global trade networks and highlighting their economic strength.

The findings indicate that monasteries served not only as religious and educational hubs but also as influential economic entities that had a substantial impact on the circulation of money, trade, land administration, and resource distribution throughout the high and late medieval eras. This, in turn, provides detailed knowledge of the economic elements of medieval monastic life, which goes against the prevailing focus on spiritual and cultural factors in conventional tales.

8 **"...WHAT IS ESSENTIAL IS INVISIBLE..." SOCIAL RELATIONS AND ESTATES OF THE PAULINE ORDER THROUGH GEOSPATIAL AND HISTORICAL FACTORS**

Peto, Zsuzsa (Hungarian National Museum) - Latos, Tamas (Hungarian National Museum)

The Order of St. Paul the First Hermit developed from different eremitic communities in 13th – century Hungary. The founders and donators of their monasteries represented most social classes from local, wealthy families to the King himself. The Pauline order was significant in Central Europe (including Rome) and gradually developed until the 16th century. Some of the monasteries have been preserved as ruins or have been located without any surface traces, but there are ones still to be located. Although their research started in the 19th century, in most cases only robbed and destroyed churches were partially excavated; this is why a rather scattered and limited bio/archaeological data is available from the monasteries and most features are still invisible or not even addressed by scholarship.

However, Pauline social connections and estate management can be explored through direct and indirect data by using the limited archaeological information, written sources (ca. 5000 charters) and non-destructive methods. Our aim is to present a brief outline of these, also reveal new data on Pauline monastic space, based on the recently conducted LiDAR surveys (Tamás Látos–Zsiga Zsolt), which are part of a long-term project aiming a complex digital database of the ca. 65 medieval monasteries, which operated on the territory of present-day Hungary.

Based on a variety of selected sites, representing different regions in Hungary and social interactions, the present paper addresses the following questions: what types of medieval Pauline monasteries were present in terms of location and further geospatial factors? What is the relation of these features with the Pauline estate management and social interactions? Were there any characteristics of the Pauline estate management in relation with their social interactions?

9 **HISTORY OF DECAY: POST-MEDIEVAL SMALL FINDS FROM THE BENEDICTINE MONASTERY OF ST. MARGARET IN BIJELA (CROATIA)**

Janeš, Andrej (Croatian Conservation Institute)

The monastery of St. Margaret in Bijela was one of the biggest ecclesiastical institutions of late medieval Slavonia, situated in the western slopes of Papuk hill. From its establishment during the 13th century monks and lay inhabitants interchanged as users of the abbey. By the mid-16th century and the Ottoman conquest the monastery changed hands between the monks and soldiers, since it was fortified and ideal for defensive purposes. During the Ottoman rule it was gradually abandoned with the church being burnt down during military operations of the Great Turkish war (1683-1699).

During the archaeological excavation 2012-2021 a substantial number of small finds have been found inside the church and northern cloister walk. Finds of dress accessories, horse and rider equipment, tools, weapons and book fittings are part of the assemblages found. Most of them were collected in layers of the last century before the complete abandonment of the monastic complex, from the second half of the 16th century onwards. The collection of finds is composed mostly of finds used by the soldiers occupying the fortified monastery during the wars with the Ottomans. Combined with the burials that continued in the church under Ottoman rule they are the evidence of habitation and every day life in the fortified monastery that was not known from contemporary written sources.

1149 **MODELLING AS COLLECTIVE UNDERTAKING: BEST PRACTICES IN BUILDING AN OPEN ACCESS LIBRARY FOR AGENT-BASED MODELLING IN ARCHAEOLOGY**

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Daems, Dries (KU Leuven) - Verhagen, Philip (VU Amsterdam)

Session format: Workshop

Archaeologists are increasingly relying on computer simulations to reconstruct and understand past societies. They are successfully building and running simulations of agrarian production, trade, settlement development and movement, to name a few. While methods such as agent-based modelling are increasingly carving out space, further integration with the broader discipline remains hampered due to limitations in technical skills and the lack of possibilities for modellers to cumulatively build on each other's work. This is predominantly due to the lack of appropriate tools and platforms enabling closer integration.

To remedy this situation, the NAS2A project (Network for Agent-based modelling of Socio-ecological Systems in Archaeology; <https://archaeology-abm.github.io/NASSA-hub/>) is developing an open library of model algorithms and code for modelling of socio-ecological systems in archaeology. It aims to redefine current practices in collaboration and synergy in modelling communities by developing an openly available and functional models library, offering a host of elements (modules, techniques, algorithms, how-to's/wikis etc.) as modular building blocks for elaborate and case-driven models and research questions. In this roundtable, we will present the project's first results towards developing the necessary infrastructure and standards, discuss and update current best practices, provide hands-on practice with creating and submitting modules to the open library, and stimulate general discussion centred around the following questions:

- 1) How can we ensure that model elements can be used for a wide range of research questions?
- 2) How can we facilitate interaction, comparison and testing of models across platforms and programming languages?
- 3) How can we achieve a sustainable infrastructure for this?
- 4) How can we teach modellers to submit their modules to the open library?
- 5) What more is needed to make simulation modelling accessible to a wider community of archaeologists?

1150 **CAVES AND ROCKSHELTERS AS ARCHIVES TO STUDY PROCESSES OF CHANGE**

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: Bergsvik, Knut Andreas (University Museum, University of Bergen, Norway) - Boethius, Adam (Dpt of Archaeology and Ancient History, Lund University, Sweden) - Jørgensen, Erlend (Norwegian Institute for Cultural Heritage Research NIKU Tromsø)

Session format: Regular session

Caves and rockshelters possibly represent the most striking site type in the global archaeological record and showcase deep sequences of anthropogenic deposits covering every period of human prehistory and history. Contrary to open-air sites, where organic materials rarely preserve, rockshelter occupations frequently resulted in cultural deposits consisting of a wide range of organic remains, spanning artifacts, zoological and human osteological remains. Some sites have also been subject to re-use, resulting in otherwise unobtainable archives of materials spanning several millennia. Such sites are crucial for reconstructing past cultural and natural systems, as they offer opportunities to study changes, not only in human societies, but also in the natural environment.

In this session we welcome contributions on two specific topics:

- 1) To explore the wide scientific research potential offered by anthropogenic cave deposits, acting as proxies for the study of long-term change. Questions may include: How do such sites compare to the data from open-air sites? How "representative" are they of general economic, social, and ecological developments? How can analyses of artifacts, soil, bone, and shell contribute to the study of changes within these domains?
- 2) To investigate and help re-engage the rich legacy datasets from old cave and rockshelter excavations. Many of the richest sites were found and excavated already during the 19th century, leaving very little for later investigations. What is the status of this material today, and what is the potential for new laboratory investigations? How can we engage with the leftovers from the early archaeologists? Are there still intact deposits preserved at the old sites suitable for the study of long-term change? Do we know about all the important sites, or are there still rich caves or rockshelters waiting to be found and excavated? How can such sites be found, and what characterizes their site locations?

ABSTRACTS

1 **METHODS FOR RECONSTRUCTING DEPOSITIONAL HISTORIES OF ANTHROPOGENIC, SEDIMENTARY RECORDS: THE CASE OF THE HOLOCENE-DEEP KIRKHELLAREN CAVE DEPOSITS, COASTAL ARCTIC NORWAY**

Jørgensen, Erlend (NIKU - Norwegian Institute for Cultural Heritage Research) - Martens, Vibeke (NIKU - Norwegian Institute for Cultural Heritage Research) - Solem, Dag-Øyvind (NIKU - Norwegian Institute for Cultural Heritage Research) - Nau, Erich (NIKU - Norwegian Institute for Cultural Heritage Research)

Anthropogenic sedimentary records are increasingly recognized as key archives for archaeological and palaeoecological research, acting as time capsules for reconstructing past states of cultural and natural systems. In this paper, we present a novel methodology for reconstructing formation processes of archaeological depositional sequences by combining multidisciplinary analyses of unique, Holocene-wide cave deposits, located on a remote coastal island in Arctic Norway. The protocol comprises extensive GPR surveying that is correlated with geochemical analysis and

in-situ environmental monitoring for sedimentary fingerprinting and forecasting of future preservation conditions for invaluable post-glacial organic remains. Sub-surface deposit characteristics are then integrated with a high-precision, laser-based 3D-reconstruction of the cave, enabling triangulation with historic photos that facilitate modelling and quantification of erosional history since 1900. The results of the applied protocol showcase detrimental depletion of critical organic heritage that had been preserved for 10,000 years - accelerated by removal of protective and compacted surface layer in the 1930's - as well as sub-surface deposits are trending towards a critical threshold for accelerated in situ degradation. The results act as a direct validation of the methodology, which facilitate the joint spatial distribution and calculation of mass/volume loss following erosion. Measures for future protection of similar archaeological deposits are discussed, as well as outlining the general applicability of the protocol/methodology.

2 CAVES AND ROCK SHELTERS IN SOUTHEAST NORWAY - GIS-BASED ANALYSIS OF LOCATIONS

Gjerpe, Lars Erik (Museum of Cultural History University of Oslo)

More than 1000 caves and rock shelters are known in the South-Eastern region of Norway. This is probably just a part of all such geological formations, as the total number is not known. However, we know a good number of them have been used as living or working spaces during the past 10,000 years. Only a fraction of the sites have been examined for evidence of human activity, and an even smaller part have been subjected to archaeological excavations. Currently, there is no comprehensive review of the material or research on how their use changes over time, but the research potential is large, as will be demonstrated in this paper. Along with a first comprehensive presentation of the record, a systematic examination of the proximity of caves and rock shelters to resources such as grazing lands, arable land, big game, fish, etc., and how these changes over time, will be presented. This provides a potential understanding of both the function of the rock shelters and the use of the landscape. Through a GIS-based study I also point out how this potential can be further utilized.

3 IN SEARCH OF THE NORTHERN PIONEERS: INVESTIGATING THE POTENTIAL OF THE UNEXPLORED CAVES AND ROCK SHELTERS OF KULLABERG, SOUTHERN SWEDEN

Boethius, Adam (Department of Archaeology and Ancient History, Lund University) - Fauvelle, Mikael (Department of Archaeology and Ancient History, Lund University) - Jordan, Peter (Department of Archaeology and Ancient History, Lund University) - Jennbert, Kristina (Department of Archaeology and Ancient History, Lund University) - Fjellström, Markus (Department of Archaeology and Ancient History, Lund University) - Hammarlund, Dan (Department of Geology, Lund University) - Rundgren, Mats (Department of Geology, Lund University) - Heintzman, Peter (Department of Geological Sciences, Stockholm University) - Bennike, Ole (Geological Survey of Denmark and Greenland)

During the Last Glacial Maximum, Fennoscandia was devoid of human life and covered by a vast and thick ice sheet. With the onset of deglaciation, the first land to emerge from the ice in southern Fennoscandia was Kullaberg. Around 17,000 years ago it formed an exposed rocky island whose upper levels contained lakes and wetlands and its side had numerous caves and cliff overhangs. Kullaberg was rapidly colonised by plants and animals found in the Arctic today, evidenced by pollen and plant macrofossils preserved in lakes and peatlands and a bone from a polar bear, which would have been exploiting local seal populations.

The Kullaberg landscape offers a multi-period archaeological sequence, with a significant research history. Numerous lake-sediment and peat sequences and unique archaeological features such as caves and rock shelters are ideal for recovering organic materials and other archaeological and palaeoecological data from the earliest human presence in Fennoscandia. Kullaberg presents unique conditions for archaeological excavation and environmental sampling through geological coring. Furthermore, of 24 known caves only 3 have been excavated, with minor sampling of 2 more. This work has confirmed that the caves yield diverse assemblages that span the Holocene. Kullaberg's complex microtopography also includes multiple rock shelters associated with landing sites and access routes to the sea, none of which have been excavated.

With this paper, we want to address the area of Kullaberg and discuss the possible potential of the multitude of un-excavated caves and rock shelters in the area. We also want to discuss how to approach the uncertainties related to un-investigated potential sites within a natural reserve, where minimal modern encroachment is permitted, and how to correlate and link cave/rock shelter data to environmental data obtained from nearby wetlands.

4 A ROCK SHELTER LANDSCAPE - NEW DATINGS AND RESULTS FROM THE REINHÄUSER FOREST SOUTH OF GÖTTINGEN, LOWER SAXONY, GERMANY

Böckenförde, Tilman (Georg-August-Universität Göttingen) - Riede, Felix (Aarhus University) - Terberger, Thomas (Niedersächsisches Landesamt für Denkmalpflege; Georg-August-Universität Göttingen)

Rock shelters have had a significant impact on the research history of European Pleistocene archaeology. In central Germany, especially in the south of Lower Saxony, about 1600 sandstone rock shelters have been documented, many

of which are archaeological sites. Excavations by Klaus Grote in the 1980s in the Reinhäuser Forest south of Göttingen revealed rock shelters with well-preserved stratigraphies. Most important was the discovery of Laacher See tephra and archaeological layers of the Middle Palaeolithic, Late Upper Palaeolithic (LUP; Magdalenian), and Final Palaeolithic (Federmesser) at a few sites. There are other Magdalenian sites in the upland zone of Lower Saxony and northern Hesse. However, none of them exhibit a comparable quality of organic material preservation. In particular, the rock shelters of Bettenroder Berg IX, Allerberg, and Abri Stendel XVIII have yielded a variety of faunal taxa, including bones with cut marks that provide clear evidence of human activity. Among other things, the analysis of the microfauna has been effective in reconstructing regional climatic conditions. In 2023, re-analysis of the Magdalenian sites and new excavations at Abri Stendel XVIII started. The talk will summarize the new results and discuss the evidence on the background of the Magdalenian sites in the northern upland zone. The area represents the northern border of the Magdalenian territory ca. 15,500 years ago and is a bridge to the LUP sites of the northern lowlands (Hamburgian; GI 1e, ca. 14,700-14,000 calBP). The rock shelters of the Reinhäuser Forest provide an excellent opportunity to characterize the way of life of LUP hunter-gatherers and the climatic conditions of the region around 15,000 calBP and their role in the subsequent re-colonization of the northern lowlands.

5 INTEGRATED METHODOLOGY FOR THE DISENTANGLING OF A COMPLEX CAVE STRATIGRAPHY AT THE MIS-3 SITE OF GERMOLLES IN SOUTHERN BURGUNDY

Andrews, Robin (Early Prehistory and Quaternary Ecology, Department of Geosciences, University of Tübingen)

Cave sites pose a particular problem to archaeologists. On the one hand, they present as striking landmarks and natural shelters, that were often repeatedly used throughout time - but on the other hand they are subject to numerous interwoven site formation processes which produce complex stratigraphies. This is doubly the case for those cave sites which were recognized early in the history of our discipline as exceptional archives of the past and were thus subject to early excavation. The Grotte de la Verpillière I near Germolles in southern Burgundy is one such site. Discovered in 1868, it was already declared to be archaeologically exhausted less than ten years later. Nonetheless, it was repeatedly excavated until the mid-20th century and featured prominently in the contemporary scientific discourse. The site is particularly noteworthy for its exceptional record of the Middle to Upper Palaeolithic transition during MIS3. But its assemblages, while impressive, were perceived to be mixed and incohesive. Recent excavations by a team from the University of Tübingen have uncovered a complex picture of site formation, intercut by old trenches. Isolated pockets of intact sediment have been discovered, but their correlation and integration into a cohesive stratigraphy have proven difficult. Here we present the outline of a methodology to disentangle the complex stratigraphic situation at Germolles. This follows an integrated approach of three main investigations: geoarchaeological profiling of sedimentary processes and episodes of alteration, absolute dating of remains from sedimentary pockets, and comparative analysis of the material culture found within. The goal of the analysis is to reconstruct the sequence of occupations at the site, provide a chronological framework for the region, and allow us to tackle further questions about human actions and interactions during the transition from the Middle to the Upper Palaeolithic in eastern France.

6 LAVA TUBES AS UNTAPPED SOURCES OF NATURAL AND CULTURAL ARCHIVES: CASE STUDIES FROM ARABIA

Stewart, Mathew (Griffith University) - Groucutt, Huw (University of Malta, Malta) - Al Shdaifat, Ahmad (Al al-Bayt University, Jordan) - Richter, Tobias (University of Copenhagen, Denmark)

In recent years, archaeological research has spotlighted the key role that the deserts of Southwest Asia played in the emergence of the Neolithic. While discussions regarding Neolithization have traditionally centred on the Fertile Crescent, recent research points to key cultural developments in the arid regions to the south and east. Here, the Neolithic took on a unique form with subsistence economies centred around highly mobile cattle and caprid herding supplemented with hunting, foraging, and trading. This period also saw a drastic rise in anthropogenic impacts on dryland ecosystems. Human activities such as husbandry and overhunting are believed to have significantly reduced landscape stability and driven desertification, simultaneously diminishing vegetation, and reducing ecosystem productivity.

Despite these recent progresses, our understanding of the region remains constrained by the limited available palaeobiological and palaeoenvironmental records. This is particularly the case when contrasted to neighbouring areas like the Levant and eastern Africa where conditions for the preservation of organic materials are more favourable. There is therefore a desperate need to locate settings in these dryland ecosystems conducive to the preservation of organics. Here, we report on our preliminary work on lava tubes from two regions—Harrat Khaybar in Saudi Arabia, and Harrat al-Sham in eastern Jordan. Although these sites have long been known, none have been subjected to systematic archaeological survey or investigation. Our pilot work revealed that these protected cave sites contain copious amounts of exceptionally preserved faunal remains—as well as cultural materials—dating as far back as Neolithic. Lava tubes therefore have tremendous potential to fill in the large gaps in palaeobiological data in a region where the preservation of organic materials is otherwise remarkably poor.

7 DIFFERENTIATED USE OF ROCKSHELTERS RELATED TO CHANGES IN THE AGRICULTURAL SETTLEMENT DURING THE EARLY IRON AGE IN SOUTHWEST NORWAY

Meling, Trond (Museum of Archaeology, University of Stavanger)

There is consensus among archaeologists that rockshelters in the lowland of the southern part of Norway were occupied at a seasonal basis during the Early Iron Age by local farmers who had their main settlements within the agrarian landscape. However, the use and exploitation of rockshelters has been very diverse during this period. While some were visited sporadically and for short periods only, others have thick cultural layers and a variety of archeological and faunal remains revealing a wide range of activities and a more regular use.

During the Early Iron Age, there were also major changes in the agricultural settlement in this region, particularly in how farms were organized and structured in the landscape. In the Pre-Roman Iron Age existing farm areas expanded and new land was cleared to facilitate farming, grazing and the construction of settlements, while the farms became more fixed with a permanent location in the landscape during the Roman and Migration Periods.

In this paper, I discuss how the changing settlement structure may have influenced the occupation of rockshelters in Rogaland, Southwest Norway. The focus will be on why some rockshelters were abandoned during the Early Iron Age, while the use of others was taken up, changed character, or became more intensified.

8 REVISITING THE CAVE DOLLSTEINHOLA AT THE NORWEGIAN COAST

Bergsvik, Knut Andreas (University of Bergen, Norway) - Meijer, Hanneke (University of Bergen, Norway)

The cave Dollsteinhola at Sandsøya, Southern Sunnmøre is situated at the top of a steep talus slope facing the North Sea. It has been formed by sea-waves and a rockshelter in front was investigated during 1951-54 by the archaeologist Erik Hinsch. His excavations yielded a large faunal assemblage with shells and over 70.000 bones, as well as bone tools and stone artifacts. Radiocarbon dates performed during the 1980s and evaluations of the lithic tool assemblage has indicated an age range of the deposits spanning 6600-3600 cal BP. The site has, however, remained largely unpublished until now. We have therefore launched a new project where the first step is to re-date and evaluate the stratigraphy of the site. This is necessary because we cannot be sure about the precision of the 1950s excavations, and the character of the occupations. A second step is to perform a new analysis of the long-term human use of Dollsteinhola. The new and extended radiocarbon dating efforts has given good results, as the nineteen new dates from four units clearly indicate that the 1954 excavation was carried out with sufficient precision. This has prompted us to move forward with re-analyses of the osteological and artefactual materials. The new radiocarbon dates indicate that the faunal sequence of Dollsteinhola is much longer than previously thought and covers most of the Holocene. The faunal and archaeological data suggests that different accumulating agents were present within the Dollsteinhola assemblage at different time periods. Although the first evidence for humans along the Norwegian west coast coincides with our earliest dates, the first human activity at Dollsteinhola appears to start in the Neolithic phase. From then on, like many other caves and rockshelters along the Norwegian coast, it was used for short term occupations until the early Iron Age.

9 THE EARLY ARCHAEOLOGISTS AND THE ISSUE OF MEDIEVAL AND POST-MEDIEVAL RECORDS FROM THE CAVES OF THE CRACOW UPLAND (SOUTHERN POLAND)

Wojenka, Michal (Institute of Archaeology Jagiellonian University)

The Cracow Upland, a karstic-rich region situated in southern Poland, is a benchmark for Polish speleoarchaeology. The caves and rockshelters situated there have been attracting professional and amateur archaeologists since 1870s. In this area, as elsewhere in Central Europe, the first decades of scientific interest resulted in broad-scale excavations in caves. This early examination has brought to light a large number of finds. Apart from prehistoric objects, these include thousands of medieval and post-medieval artefacts.

The aim of this paper is twofold. First, I would like to focus on the actual state of preservation and examination of the finds representing historical periods, discovered during the early stages of archaeological excavations (1871-1918/1919). To see the scale of losses resulting from the methods then applied, the material in question will be compared with assemblages obtained from modern-era archaeological excavations in cave sites. Secondly, I would like to describe the current scientific potential of both the material unearthed and the sites explored by the pioneer archaeologists. As evidenced by the most recent studies, the informative potential of both in many cases is still high.

10 NEW EXCAVATION OF CAVES AND ROCKSHELTERS IN RUŽÍN (EASTERN SLOVAKIA): PRELIMINARY RESULTS OF MULTIDISCIPLINARY RESEARCH

Nemergut, Adrián (Institute of Archaeology, Slovak Academy of Sciences, Nitra) - Soják, Marián (Institute of Archaeology, Slovak Academy of Sciences, Spišská Nová Ves) - Lisá, Lenka (Institute of Geology, Czech Academy of Sciences, Praha) - Hajnalová, Mária (Constantine the Philosopher University in Nitra) - Orvošová, Monika (Slovak Museum of Nature Protection and Speleology, Liptovský Mikuláš) - Čejka, Tomáš (Institute of Botany, Slovak Academy of Sciences, Bratislava) - Popovičová, Lucia (Institute of Archaeology, Slovak Academy of Sciences, Nitra) - Mihályiová, Jana (Institute of Archaeology, Slovak Academy of Sciences, Nitra) - Čeklovský, Tomáš (Slovak Museum of Nature Protection and Speleology, Liptovský Mikuláš) - Obuch, Ján (Slovak Museum of Nature Protection and Speleology, Liptovský Mikuláš)

In the Ružín krast (Eastern Slovakia), several caves with evidence of prehistoric human presence were excavated during the 19th and 20th centuries. The most famous are the Veľká ružínska Cave, the Antonova Cave and the Medvedia Cave. The Palaeolithic occupation was identified in the Veľká ružínska Cave and the Mesolithic finds were found in Medvedia Cave. Veľká ružínska and Antonova Caves were intensively used in the Neolithic period.

The aims of the new excavations which started in 2022 at the Miriama rock-shelter and continued in 2023 at the Veľká ružínska Cave were to verify Palaeolithic and Mesolithic occupation, clarify the stratigraphy of the sites and obtain palaeoecological data for validation of existing hypotheses regarding the evolution of climate and environment and their impact on prehistoric human societies in the (micro)region.

Our results show that the sediment formation in the Miriama rock-shelter occurred between 9.3–4.7 ka uncal BP with the main occupation horizons during the Mesolithic, Neolithic and Eneolithic periods. New excavation in the Veľká ružínska Cave exposed deposits and artefacts associated with the Upper Palaeolithic (26-30 ka uncal BP) and the Neolithic (6.1 ka uncal BP) occupations.

In this paper, we present results of integrated analysis of stratigraphy, soil chemistry micromorphology, artefacts (lithics, pottery, an antler point artefact), ecofacts (faunal and floral remains) and their radiocarbon dating.

11 LEGACY EXCAVATION IN THE FRANCONIAN JURA. CHALLENGES AND OPPORTUNITIES

Burgdorf, Phil (University of Bamberg)

The Franconian Jura is a low mountain range located in southern Germany and one of the largest karst landscapes in the country. During four hundred years of research, artefacts from the Palaeolithic to post-medieval periods were discovered in over 300 caves. Over 600 research activities in caves resulted in a substantial amount of legacy data being held by local collections and institutions. There are several challenges associated with legacy data, including lack of documentation, fragmentary finds, and chronological issues. This combination often leads to challenges in the interpretation. Unfortunately, researchers often fail to recognize or take advantage of the potential of this legacy data. We challenged this data in a research project.

Human remains were deposited in many vertical caves of the Franconian Jura for an extended period of time. There is an ongoing discussion about whether these human remains are related to burials or other types of body rituals. Data from legacy excavations from the early 20th century are used to provide a valid database for evaluating a selection of sites with anthropogenic deposits, including human remains.

The outstanding preservation of bones provides ideal conditions for C14-samplings, analysis on Stable Isotopes and aDNA. A series of C14-datings sampled from human bones revealed much more deposition phases than represented by the enclosed finds. Some of the preserved floor plans illustrate the distribution of finds, providing the opportunity to create a simple distribution pattern. These patterns are mandatory to answer the question of how the human remains (bodies) and artefacts were deposited. Newly discovered caves, as well as well-known sites, have the potential for further excavations. However, legacy data will still be required for evaluating many cave sites. Therefore, it is important to create strategies that allow a comparison of legacy excavations from different areas.

1151 TIME FOR BIG CHANGES: TRANSFORMATIVE AND PERSISTENT IMPULSES IN THE 4TH AND 3RD MILLENNIA BC EUROPE

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Diniz, Mariana (Centre for Archaeology - UNIARQ; School of Arts and Humanities; University of Lisbon) - Cerrillo, Enrique (Dpto. de Prehistoria, Historia Antigua y Arqueología; Facultad de Geografía e Historia; Universidad Complutense de Madrid) - Gottardi, Corina (University of Bern) - Schiess, Delphine (University of Bern) - Nordqvist, Kerkko (Helsinki Collegium for Advanced Studies)

Session format: Regular session

After the first agro-pastoralist societies spread throughout Europe, persistent features—such as agriculture, husbandry, and village life, among others—entered the landscape and became a main element of European prehistoric trajectories. These communities, first part of wider cultural entities, as the Linearbandkeramic or Impressa circles, developed into more regionalized groups, where, however, big trends as Megalithism reflect how deeply connected those societies were.

By the end of the 4th millennium and during the 3rd millennium BC, a Great Acceleration—similar, but at a different scale, to the one that characterizes the 3rd millennium AD—took place in diverse areas of Europe.

The archaeological record reflects an unprecedented demographic growth and complexification of economic, technological, pottery production, social, and symbolic aspects of life and death, strongly related to inter-regional and long-distance contacts.

This session welcomes all who want to debate the ways and scenarios in which the 4th and 3rd millennia BC Big Changes took place, from demographic growth to settlement patterns, exotic consumption, and social changes also paying attention to enduring features that, side by side with change, shaped prehistoric societies.

ABSTRACTS

1 THE INTENSIFICATION OF THE 4TH MILLENNIUM CAL BC IN SOUTHWESTERN IBERIAN PENINSULA: A COMPREHENSIVE EVALUATION FROM MULTIPROXY DATA

Cerrillo-Cuenca, Enrique (Dpt. of Prehistory, Ancient History and Archaeology, Complutense University, Madrid, Spain; GIAP - Grupo de Investigación en Arqueología Prehistórica, Complutense University, Madrid, Spain) - Almeida, Nelson (Department of History, University of Évora, Évora, Portugal; Uniarq, Centre for Archaeology, University of Lisbon, Lisbon, Portugal)

In the trajectory of the Late Prehistory in the Iberian Peninsula, the clearest processes of intensification apparently occur during the transition from the 5th to the 4th millennium cal BC and during the 3rd millennium cal BC. Various indicators from the archaeological record have been used to identify the nature, intensity, and significance of these processes of social, ideological, and technological transformation.

With the configuration of communities at the end of the Neolithic, exchanges of personal adornment items have been taken as indicators, but also the very entity and diversity of megalithic architectures. However, even with an archaeological record that is not very expressive and biased, it is necessary to evaluate this increase with indicators such as the intensity and variety of landscape occupation and the chronometric models, to which we can associate other evidence such as archaeozoological data, since the exploitation of other biotic resources is still scarcely characterized. This communication aims to present the still open questions and explore avenues that allow explaining the nature and scope of the transformations that occurred in the 4th millennium cal BC in southwestern Iberian Peninsula, especially the basins of the Tagus and Guadiana.

2 BETWEEN THE 4TH AND 3RD MILLENNIUM BC IN ALTO DOURO (NORTH OF PORTUGAL). WHAT HAPPENS IN THE LANDSCAPE

Muralha, João (FCSH / Universidade Nova; CHAM)

In the Portuguese Alto Douro region (North of Portugal), between the 4th and 3rd millennium BC, we witnessed major transformations in the archaeological record, especially in the type of geomorphological implantations of archaeological sites. While in the 4th millennium BC the settlement was of low density, small open-air settlements, and occupations in rock shelters, from the beginning of the 3rd millennium, there were changes. We will find them at the top of major geomorphological specificities, on ridges, in plain areas, on mid-slopes and at the bottom of valleys. There is also diversity in terms of the structures found, in the 3rd millennium BC they seem to become more complex. There also appears to be demographic growth if we look at the number of new archaeological stations and, among those that have been excavated, the quantity and diversity of objects is surprising. With this communication we intend to make

3 AGRA DO CASTRO. A CONTRIBUTION TO THE UNDERSTANDING OF THE 3RD MILLENNIUM BC IN BEIRA LITORAL (PORTUGAL)

Branco, Gertrudes (University of Évora/(CHAIA))

In the last two decades, Portuguese archaeology has been dominated by preventive and minimization actions, which account for around 95% of the work carried out, with a total of more than 1,800 authorizations granted each year (data from 2023).

This work has produced a growing amount of archaeological data which, unfortunately, does not translate into an exponential increase in the volume of knowledge, produced and shared, about the dynamics of occupation of territories, of life and death, during the different (pre)historical eras.

In this context, take place various interventions, since 2003, at the archaeological site of Agra do Crasto (Aveiro), located at one of the western extremes of the European continent, on the northwestern Atlantic coast, in the current lagoon environment of Aveiro (Aveiro, Portugal).

Preliminary studies show the existence of material and structural evidence documenting a temporary occupation, apparently discontinuous, from the Ancient Neolithic, Chalcolithic, Iron Age, medieval and subsequent historical periods.

Our contribution results from the analysis of the documentation produced, and the study of the materials collected, during the archaeological work carried out, which report an intervention, at different times and in different places, in three negative structures, interpreted as “ditches”, consistent with an occupation from the Chalcolithic period.

Could the archaeological site of Agra do Castro be the westernmost testimony to a phenomenon of cultural identity that extends from the Iberian Peninsula to northern Europe during recent prehistory, with “ditch enclosures” as one of its monumental expressions?

How can this site be integrated into the process of neolithization of Beira Litoral, which, according to some authors, was accompanied by the construction of ditch enclosures, walled enclosures and megalithic monuments?

What is the contribution of preventive and minimization archaeology to clarifying these questions regarding the knowledge and chrono-cultural integration of the Agra do Crasto archaeological site?

4 DIFFERENT FEATURES FOR DIFFERENT WORLDS? POSITIVE AND NEGATIVE ARCHITECTURES DURING THE CHALCOLITHIC IN CENTRAL AND SOUTHERN PORTUGAL

Ribeiro, Inês (CHAIA/Universidade de Évora) - Diniz, Antonio (CHAIA/Universidade de Évora) - Almeida, Nelson (CHAIA/Universidade de Évora) - Rocha, Leonor (CHAIA/Universidade de Évora)

The last decades were marked by the development of new techniques and areas of research that have also been applied to the 3rd millennium BCE European archaeological records. In Portugal, this development was accompanied by an empirical “revolution” due to the identification of numerous ditched enclosures. This, together with the previously known records of walled enclosures, makes Central and Southern Portugal an interesting and privileged scenario in which to discuss different dynamics related to the Chalcolithic.

The Chalcolithic archaeological record has been widely discussed, also concerning territorial occupation and exploitation dynamics. Within this topic, there has been a growth focused on the spatial and chronological evidence related to ditched and walled enclosures. These two realities tend to be separated by archaeologists, being mostly evidenced in different parts of the country, with walled sites in the Estremadura region but also occurring further South, and ditched enclosures concentrated in the latter areas. Nonetheless, as it happens elsewhere (e.g., San Blas, Cheles, Spain), these types of features can “coexist” in the archaeological records (e.g., Monte da Ponte, Évora, Portugal).

In this communication, we will sum up existing evidence concerning the location, typology, chronology and associated materials for enclosures in Central and Southern Portugal that were submitted to archaeological excavations. We aim to contribute to discussions on their paper in the broader spatial organization and distribution, their main similarities and differences.

5 BURIAL TAPHONOMY AND MEGALITHIC RITUAL PRACTICES IN IBERIA: THE PANORÍA CEMETERY

Vílchez Suárez, Miriam (University of Granada) - Aranda Jiménez, Gonzalo (University of Granada) - Díaz-Zorita Bonilla, Marta (University of Tübingen) - Robles Carrasco, Sonia (University of Granada) - Sánchez Romero, Margarita (University of Granada) - Milesi García, Lara (University of Málaga) - Becerra Fuelle, Paula (University of Granada)

The bioarchaeological study of collective tombs involves facing complex ritual practices determined by the special nature of these archaeological contexts. The frequent use and reuse of megalithic monuments has created multiple ritual deposits consisting of masses of stratified, fragmented and mixed human bone remains that are found piled on top of each other. Understanding the formation of these bone assemblages is essential to be able to construct accurate narratives about megalithic funerary rituals and possible differences in mortuary treatment between the 4th and 3rd millennia BC. The cemetery of Panoria (Darro, Granada) offers an excellent opportunity for exploring the ritual variability through the study of funerary taphonomy, as four of the nine recently excavated dolmens are in a remarkable state of preservation (Tombs 3, 10, 11 and 15). Based on a multi-proxy approach different variables such as the characteristics of the archaeological context, taphonomic agents, the application of statistical indices of bone representation and preservation, and radiocarbon dating were integrated and interrelated. From this approach, three main ritual practices have been outlined: i) Primary sequential inhumations followed by the differential in situ decomposition of skeletal remains; ii) The selective removal of crania and long bones; and iii) The curation of subadult bone remains. The use-life of tombs, the intensity of mortuary depositions and the intentional protection of specific bones appear as key aspects for understanding the variability in bone assemblage formation.

6 "I COULD BRING YOU JEWELS - HAD I A MIND TO". FROM "EXOTIC" GRAVE GOODS TO INTERREGIONAL CULTURAL INTERACTION

Corga, Mónica (UNIARQ - Centro de Arqueologia da Universidade de Lisboa. Faculdade de Letras de Lisboa; Morph | Grupo Dryas) - Almeida, Miguel (Morph | Grupo Dryas; UNIARQ - Centro de Arqueologia da Universidade de Lisboa. Faculdade de Letras de Lisboa) - Aubry, Thierry (Fundação Côa Parque; UNIARQ - Centro de Arqueologia da Universidade de Lisboa. Faculdade de Letras de Lisboa) - Aires, Sílvia (Fundação Côa Parque; Instituto de Ciências da Terra - Pólo da Universidade do Porto)

An important period for understanding European history, the 3rd millennium BC is characterised by the emergence of dominant centralities, progressive social stratification, geographic expansion of cultural, political, and symbolic interactions, intensification of natural resource exploitation, and the anthropization and monumentalization of landscapes.

The ditched enclosure of Porto Torrão (Ferreira do Alentejo, Portugal) is one of these Iberian central places, preserving a remarkable range of mortuary practices and contexts from the end of the 4th to the end of the 3rd millennium BC. Human remains are found both within and outside the enclosed area, in ditches, pits, or collective tombs, in clusters or isolated, as primary depositions or displaying intense manipulation.

In the tholos type tombs of Horta do João da Moura 1, located outside Porto Torrão, the existence of large-scale economic and social interaction networks is purposefully made visible during funerary performances through the introduction of foreign goods in greater quantities and variety than before. These include lithic tools, gold artifacts, cinnabar, limestone vessels, and marine shells, documenting interactions with different peninsular areas.

Considering the potential of mortuary behaviours to display, but also to create, and recreate social and political relations, we compare these "exotic" grave goods from Horta do João da Moura 1 to those from other funerary contexts in Porto Torrão, such as the rock-cut tombs of Monte do Carrascal 2, in order to discuss their ontological place in ritual performances, the persistence, disappearance, and change of their intentional and tangible outcomes that may shed light on the evolution of the attitudes towards death and the dead, as well as the underlying economic, social, and cosmological order.

1154 STONE AGE THEORY IN AN UNDEFINED PARADIGM: GEN-Y TO Z, THIRD SCIENCE REVOLUTIONS TO NEW MATERIALISMS

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Blaesild, Paulina (University of Gothenburg) - Kilhavn, Håvard (University of Stavanger) - Solfeldt, Erik (Stockholm University)

Session format: Workshop

The aim of the workshop is for Stone Age archaeologists to come together and discuss the positions of current theoretical perspectives within Stone Age archaeology. We are especially interested in the voices of early career Stone

Age archaeologists. Does it make sense to talk of a theoretical "mainstream" within Stone Age archaeology today, or has the field become so theoretically diffused that no such mainstream exists? Have we lost capacity to judge out mainstreams in today's discussion climate (or, were we ever capable?). What are the main theoretical "schools" we encounter in the current "PPP", "tech-individualist" or "representationalist" era, how do they relate to one another?

We experience increasing tendencies towards theoretical specialization and less engagement, dialogue across theoretical divides of the kind characterizing for the 1990s and early 2000s. We believe the implosion of previous theoretical jargon has restricted ways of interacting across discursive borders, where conflict is avoided through silenced dialogue. We also note increased tendencies towards focuses on practice and proxy rather than interpretative framework, maybe as a result of the so-called "third science revolution". This situation will not result in less interpretative archaeologies but instead, in obscured knowledge production and blurry narration of the past. We welcome a discussion about how contrasting theoretical approaches may enter into dialogue about commons and uncommons: to the benefit of both. The workshop will provide space for inclusive, friendly, and informal discussions, and we welcome participants with diverse backgrounds and interests. At the end of the workshop, our aim is that all participants will contribute to identifying central, theoretical issues in Stone Age narration. Using this framework, participants will also get an opportunity to connect with others equally interested in Stone Age archaeology and theory as well as the wide range of possible and strange combinations between the two.

1155 DOWN MEMORY LANE. RECURRENCES IN TRANSFORMING LANDSCAPES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: La Rosa, Lorenza (University of Oslo) - Campus, Antonio (University of Pisa) - Limina, Valentina (F.R.S - FNRS; Université catholique de Louvain)

Session format: Regular session

When tracing the history of a place, it is possible to notice how the same settlement choices can recur over time despite caesuras, changes, and transformations. Intentional and unintentional dynamics variably impact on landscape and the recurrence of scenarios can lead to question how strong the territorial vocation and the permeating memory are. Previous human actions might in fact orient following choices through long lasting transformations, creating new opportunities or imposing restrictions in new landscape arrangements.

In this session, we want to focus on how various agencies and their reciprocal interactions participate in the creation of landscapes; by emphasizing how choices can re-occur through time, we want to assess the role of memory in the construction of palimpsests. Memory is intended both as the collection of traces of previous actions embedded in a multi-layered landscape and the collective memory that engages a community of people in the social construction of a dwelt landscape.

Indeed, in a behavioral perspective, a landscape is a system defined and populated by the interactions that take place in it. This dialogic systemic view could help to highlight how recurrences and adaptations contribute in the development of a landscape and define a responsive path of choices, re-balancing a rigid dichotomy on positive and negative outcomes, and strengthening instead the repeated and prolonged efforts to negotiate with environmental features.

We welcome papers which investigate traces of change, mitigation or adaptation in landscapes, by highlighting relationships in various activities (i.e. productive, infrastructural, and settlement dynamics) and assessing how previous practices and traditions can affect forthcoming human reactions to environmental and socio-political transformations.

ABSTRACTS

1 MARGINAL MEMORIES. SOME REFLECTIONS ON MYTHS AND PERCEPTIONS OF GEOTHERMAL AND VOLCANIC LANDSCAPES IN THE ITALIAN PENINSULA

Lancini, Loredana (Université Catholique de Louvain) - Limina, Valentina (FNRS - Université Catholique de Louvain)

Studies investigating the relationship between landscape and memory within a combined anthropological and archaeological framework are still rare. Yet, this promising approach can shed new light on the perception of a given landscape not only as the sum of physical factors but as a space of shared experiences. Particular landforms can activate models of representations and peculiar narrative patterns to deal with environments merging in the collective memory. The paper focuses on two case studies (Sicily and Northern Tuscany) to reflect on the impact of landscapes featured by geothermal and volcanic phenomena in building local memory. Due to their peculiarities, these landscapes were considered marginal. Through a diachronic perspective, integrating literary sources, toponyms, archaeology, geomorphology, etc., the aim is to demonstrate these areas' centrality to the territory's historical development. In the territory of Volterra, which fascinated authors from antiquity to the contemporary era because of its peculiar land-

scapes, the toponyms in the areas of Larderello, Bagno a Morba, Bagno della Leccia, and the archaeological remains led us to reassess the importance of these 'fragile' and 'marginal' zones where myths and religion blurred with political control and management of resources. In Sicily, ancient authors recorded stories related to the volcanic landscape and the perception of its danger; later, Christian legends, tales of travelers of the Grand Tour, and contemporary folklore pick up on similar narrative patterns. These case studies will enhance our understanding of how oral histories constitute a common ground, strengthening the sense of territorial rootedness and contributing to the reaffirmation of identities. Moreover, by approaching the case studies with a flexible anthropological approach and considering modern oral sources, it would be possible to reflect on the recurrent topoi in perceiving those 'marginal' and still inhabited landscapes often central to local economies and identity.

2 EXSULTANTIBUS UNDIS. THE RIVER ACI AS LANDSCAPE MAKER, BETWEEN AFFORDANCE AND MEMORY.

La Rosa, Lorenza (University of Oslo)

A famous myth told by Ovid (*Metamorphoses* 12.750-897) recounts the tragic story of the young shepherd Aci killed out of jealousy by the Cyclops Polyphemus and transfigured into a river. The Aci River flowed in eastern Sicily, just north of Catania, and gave its name to the Greek-Roman settlement that developed near it. Although the river is no longer visible, its memory is still alive and persists in the place-names: every town it once streamed through retains the prefix Aci to its name, furthermore its river mouth is still called "u sangu di Jaci" (the blood of Aci).

The site of Santa Venera al Pozzo (Catania, Sicily, Italy), the ancient settlement of Acium, is an archaeological palimpsest, consisting of multi-temporal features dating from the Hellenistic age to the 17th century. The evidence of the long-lasting human presence in the area is constantly connected to water, not only in the form of the river, but also of a sulfurous water thermal spring. The early Hellenistic sanctuary and settlement, the Roman baths and mansio, then the Late Antique ceramic production district, and finally the medieval and modern church and hospital, all relates to the availability of water as a resource and to the symbolic and curative properties of thermal water.

This paper aims to explore the development of the site of Santa Venera al Pozzo and its surroundings: a focus on multi-temporal history has the potential to overcome the traditional narrative dominated by the monumental Roman remains, and to show how collective memories and past experiences can delineate continuity and cohesion in community choices and shape the identity of a place.

3 GINOSA PROJECT: THE SETTLEMENT CONTEXT OF MADONNA DATTOLI SITE BETWEEN OLD EXCAVATIONS, RECENT ACQUISITIONS AND RENEWED INTERPRETATIONS

Piccenna, Simona (University of Bari Aldo Moro) - Stasi, Virginia (University of Bari Aldo Moro) - Moro, Angelo (Freelance Archaeologist) - Fioriello, Custode (University of Bari Aldo Moro) - Cerri, Laura (Freelance Archaeologist) - Rotondo, Roberto (National Superintendency for Underwater Cultural Heritage)

The knowledge of the history of the human population during ancient time around Ginosa (Taranto-Puglia-Italy) has been enriched with evidence and reflections that contribute to review the historical profile and landscape framework.

This research is part of the 'Ginosa Project': Archaeology and Landscapes', launched in 2020 under the coordination of C.S. Fioriello, in collaboration with the National Superintendency for Underwater Cultural Heritage and in agreement with the local Municipality. The investigations included the systematic analysis of the context of Madonna Dattoli, located approximately 3.5 km SE of the urbanized area of Ginosa; geophysical prospecting was carried out in the area using a magnetometer technique that can deal with both field acquisitions and interpretative data processing.

The results obtained make it possible to identify numerous linear shape anomalies generated by buried masonry structures, probably to be associated with the distinct dynamics of occupation of the site, which occurred from Roman ages, until the Late Antique and early Medieval period at least.

The settlement of Madonna Dattoli is closely and traditionally linked to the presence of water, which has thus marked the entire context over time and determined both its functional use and its sacred and ritual significance. This is evidenced not only by the recognition of even minimal structural evidence dating back to Roman period (nymphaeum, underground aqueduct, rooms with waterproof floor and wall sheathings), but also by the rural church (founded in Paleochristian times, rebuilt by Benedictine monks, renovated in modern times and still in use today) linked to the presence of water to which popular tradition assigns health-giving and therapeutic properties.

This presentation serves as a preliminary glimpse into the rich archaeological landscape of Ginosa, presenting the first results of the 2023-2024 archaeological excavation campaign, and sets the stage for further exploration and scholarly inquiry into this significant site.

4 CROPS AND MARSHLANDS, LAND USE AND RECURSIVE SETTLEMENT CHOICES IN THE AGER PISANUS (TUSCANY, ITALY)

Campus, Antonio (University of Pisa)

In Roman times, the territory of Pisae (Tuscany, Italy) was considered particularly fertile (Strab. 5, 2, 5) and must have been widely cultivated if Pliny (N.H. 18.86-87 and 109) refers to its cereal production.

This fertile and economically advantageous representation of the Pisan territory seems to be confirmed by the demographic explosion that the area experienced during the 1st-2nd centuries CE when, as a result of colonial deduction (44-31 BCE), the agrarian complexes multiplied and the settlement pattern extended, reaching its maximum expansion.

The long-term perspective from the Hellenistic age to Late Antiquity adopted in this paper contributes to refine this picture, delineating a mutable environment and emphasizing the prolonged and continuous human effort to negotiate with environmental dynamics. The adaptive nature of human communities in response to environmental, economic and socio-political transformations is revealed by recursive settlement choices even in apparently counter-intuitive instances, such as iterated occupations of areas prone to swamping and the simultaneous abandonment of apparently more suitable neighboring areas.

Applying GIS and R-based analyses, the paper explores the multiple agencies involved in settlement and land use choices from a behavioral perspective. In this way, patterns of settlement growth, contraction and/or reorganization are examined in their environmental context in order to highlight, on the one hand, the human response to changing circumstances and, on the other, the tendency to maintain previous orders, even when changes appear to undermine their balance.

5 FROM CRAFTSMANSHIP DISTRICT TO CITY AND BACK AGAIN. THE CASE OF PISA BETWEEN THE LATE REPUBLICAN AND LATE ANTIQUE PERIODS

Caroti, Alberto (Sapienza Università di Roma) - Fabiani, Fabio (Università di Pisa) - Genovesi, Stefano (Università degli Studi di Napoli "Federico II")

The urban layout of Roman Pisa remains largely elusive today due to environmental transformations and the overwhelming monumentality of the medieval city. Archaeological investigations conducted by the University of Pisa are revealing the close interrelationship between the city and the suburban area and their changing dynamics over time, with mutual expansion or contraction under the influence of local processes and broader historical contexts. In particular, at Piazza Andrea del Sarto, near the famous Piazza del Duomo where the now-disappeared river Auser flowed, research has revealed that between the late Republican and Augustan periods, the city had expanded into this area with a quarter characterized by rich domus. Investigations have also revealed that both before and after the development of the residential quarter, the area had experienced similar uses. Initially, it was occupied by buildings used for agricultural and artisanal purposes, particularly for ironworking to supply tools destined for shipbuilding industry carried out near the river. Later, in the late antique period, when the domus structures disintegrated and the city underwent a process of becoming more village-like, the area reverted to being used for artisanal activities, with workshops once again dedicated to ironworking for tools destined for a local market. What emerges, therefore, is the close interconnection between urban and suburban areas, and the adaptive nature of the urban landscape over time.

6 FROM DESTRUCTION TO RENAISSANCE: CONTINUITY AND DISCONTINUITY IN LUCCA'S MEDIEVAL URBAN LANDSCAPE

D'Antoni, Francesco (Sapienza University of Rome)

The current layout of cities with a millennium-old history typically reveals a palimpsest of the human activities and natural events that have taken place within the urban centre.

Considering the destructive phenomenon as a point of connection rather than a break, the purpose of this paper is to analyse the transformations that have influenced Lucca's medieval appearance, emphasizing the functional continuities and discontinuities that occurred in remodelled spaces.

This work will develop considering archaeological records, written sources, and the persisting medieval buildings. To highlight the remaining aspects of the medieval city, firstly we will look at the medieval remnants in the urban centre. Subsequently, this study will outline an historical account of the events that transformed Lucca since the Early Middle Ages (construction or renovation of churches, construction of military infrastructures, construction of new districts, etc.).

Furthermore, the focus will be projected around four of Lucca's main squares that were investigated by archaeological excavations: Piazza San Michele, Piazza Napoleone, Piazzale Verdi, and Piazza dell'Anfiteatro. By examining the connections between the different structures that have succeeded one another over time, the study of these urban areas

will enable us to comprehend the various processes that took place inside and outside the medieval city. According to this viewpoint, archaeological data will not be viewed as isolated accounts of a particular historical era, but rather as evidence influenced by a process of change that has its origins in the destructive event.

This work is part of a PhD project that involves creating an archaeological dataset to investigate and evaluate the changes that occurred within the modern-era walls of Lucca from the sixth to the sixteenth centuries.

7 FRAGMENTS OF AGRARIAN LANDSCAPES IN VAL DI CORNIA: RECURRENCES AND CHANGES OF AGRICULTURAL SPACES BETWEEN 18TH AND 20TH CENTURIES

Plateroti, Francesca (University of Siena) - Zanini, Enrico (University of Siena)

The Val di Cornia is a plain located next to the Piombino promontory, in the northern part of Maremma, Tuscany. A vast lagoon – known as Falesia – characterized this peculiar environment, inhabited and exploited since prehistory. This long-term occupation is documented by the archaeological site of Vignale, a villa rustica attested from III century BC to IX century AD.

During the 18th century, the heritage of the ancient settlement was symbolically embraced by an extensive agricultural estate, the tenuta di Vignale. The estate would exert a profound influence on the shaping of a pastoral and agricultural landscape, while simultaneously stimulating an initial urbanization and the maintenance of certain road structure. Finally, during the 1950s, the estate was affected by the Riforma Agraria laws; many fields were expropriated and distributed to farmers, causing the parceling and the urbanization of the estate, but also a homogenization of the agrarian landscape.

This paper aims to show changes and recurrences in the exploitation of agricultural landscapes in Val di Cornia between the 18th and 20th centuries. This study – developed as part of the current research conducted by the University of Siena on the archaeological site of Vignale – focuses on three elements: road system, farmhouses, and wetlands management, investigated through an archaeological point of view. This research therefore involved consulting and collecting available archival and photographic data, which were compared with the evidence collected on the field and then processed through QGIS.

In conclusion, the study of an agrarian landscape of the recent past seems particularly fascinating in the perspective of understanding the most recent transformations of this area and in the attempt to connect the local population to its heritage, to be considered as a “group of resources inherited from the past” as suggested by Faro Convention.

8 COMMUNITY MEMORIES PAINTED ON FACTORY SILOS: THE SECOND LIFE OF AN ECO-MONSTER OUTSIDE ROME AND A NEW IDENTITY LANDSCAPE

Bernardi, Martina (Roma Tre University)

Some urban and rural landscapes are characterized by the remains of abandoned factories, now transformed into artifacts related to industrial archaeology. These structures in the past strongly defined the identity of communities, particularly of the working-class society that developed around the production centers.

A specific case study is the complex of the quarry and the cement factory ‘CIDI’ near the hamlet of Marcellina, located about 30 kilometers northeast of Rome. This site represents a unique example of landscape changes in a rural context, closely tied to the community it once served.

This entire area has served as a quarry for an extended period due to the presence of limestone and travertine stones, which have been excellent resources for the production of building materials and lime from the Roman period up to the present day.

The factory, abandoned in the 1970s, has been recently transformed into a landmark in the contemporary landscape thanks to a project of valorization culminating in the permanent exhibition of wall paintings realized on the disused silos and depicting the past workers of the factory. The deteriorating building acts now not only as a memory marker but also as a new identity symbol integrated within the landscape, thanks to the narration of the local community’s past in the painted images.

This paper aims to illustrate through an archaeological approach how abandoned industrial complexes can acquire new significance for the community. It explores how repurposing these structures through innovative solutions can integrate them as new placemaking in the landscape while keeping the memory of the previous history. This virtuous mechanism can also create connections between the building and the local population to provide new meanings for this anthropic element, transforming them from eco-monsters into identity symbols for the community.

9 WHEN THE PAST HITS THE HERDSMAN: DIACHRONIC ANALYSIS OF AN AGRO-PASTORAL BORDER LANDSCAPE IN MARCESINA PLAIN (NORTHERN ITALY)

Zecchinato, Sara (Department of History, Humanities and Formation – University of Sassari) - Azzalin, Giovanni (Department of History, Humanities and Formation – University of Sassari) - Magnini, Luigi (Department of Humanities – University of Venice) - De Guio, Armando (Department of Cultural Heritage: Archaeology, History of Art, Cinema and Music – University of Padova)

The Marcesina Plain, is a vast basin located in the northeastern part of the Asiago Plateau. Characterized by a vast environmental variety, this territory has always represented a strong pole of attraction for anthropic occupation. Mousterian lithic tools testify to the earliest occupations of the territory, while seasonal settlements from the Upper Palaeolithic and Mesolithic demonstrate an intense exploitation of the plain by Alpine hunter-gatherers. Among the best-known Epigravettian sites, Riparo Dalmeri offers an extraordinary reconstruction of the paleo-economic and functional organization of the seasonal mountain settlements.

In terms of historical occupation, fieldwork and remote sensing analysis has revealed a very high number of malghe (alpine huts) or buildings related to agro-pastoral activities. These structural traces find comparisons in archival data: since the 16th century, various conflicts and conciliations, mainly related to grazing rights, have marked the occupation of this territory, leaving visible evidence on the ground. The importance of these alpine structures is highlighted by the continuity of their use even in contemporary times: malghe still represents the economic, cultural and identity center of the plain. Since the 20th century, the area has been affected by the events of the First World War. During the second half of the 20th century, the Plain was used as a training center for artillery of the NATO contingents. The integration of non-invasive technologies with traditional methodologies allows to identify the main changes in the territory during the different chronological phases of occupation. Finally, the diachronic study of the landscape allows us to outline how the exploitation of resources results in a continuity, not only in the occupation of the land, but also in traditions and the formation of shared (and even contested) places of memory. The case of the ‘casonetti’, disputed between historical occupants and the municipality for over ten years, is emblematic.

1157 THEORETICAL AND METHODOLOGICAL DEFINITION OF THE ‘ARCHAEOLOGICAL POTENTIAL’ IN PREVENTIVE ARCHAEOLOGY. CHALLENGES AND OPPORTUNITIES

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Boi, Valeria (Istituto Centrale per l’Archeologia (Ministero della Cultura)) - Marino, Sara (Università la Sapienza di Roma) - Castiello, Maria (University of Bern; INCIPIT - CSIC) - Bouwmeester, Jeroen (Cultural Heritage Agency, the Netherlands) - Rensink, Eelco (Cultural Heritage Agency, the Netherlands)

Session format: Regular session

Archaeological potential is an intrinsic characteristic of a given area that is expressed by the quantity and nature of sites already known and by the possibility of undiscovered archaeological evidence being preserved underground. Its determination is based on the examination of multiple factors, including human-land relationships in the past and the dynamics responsible for the construction of the archaeological stratification over time, as well as its transformation and/or removal. The determination of archaeological potential is thus a study that, starting from the historical-archaeological and paleo-environmental characteristics of the area concerned, examines its entire diachronic evolution, up to the contemporary age.

Being a predictive tool, knowledge of the archaeological potential is important both in research contexts and, above all, in the field of cultural heritage protection in relation to infrastructural planning (CRM-Cultural Resource Management). The assessment of the archaeological potential is in fact the basis for quantifying archaeological risk, that is, the degree of impact affecting archaeological sites or deposits by the implementation of an urban or rural area transformation intervention.

The assessment of archaeological potential has been considered with heterogeneous approaches:

- attributing different weights to the various factors considered.
- adopting an approach based on expert judgement either through the development of mathematical-statistical models or using remote sensing technologies.
- focusing on specific chronological/cultural phases or specific portions of archaeological landscapes.

Another element of discussion is the scale of the maps and the way the archaeological potential is depicted: for limited areas (often on specific activities); for larger areas (land-use planning activities) up to very large-scale areas.

We aim to invite scholars and professionals from different backgrounds to share their experience and present their approaches and case studies, to establish the state of the art of the research, to address the main challenges and to identify the opportunities arising from such exchange.

1 ASSESSING THE ARCHAEOLOGICAL POTENTIAL OF MESOLITHIC LANDSCAPES. A CASE STUDY FROM THE MEUSE VALLEY IN THE NETHERLANDS

Rensink, Eelco (Cultural Heritage Agency of the Netherlands)

In the Netherlands excavations carried out in the context of spatial developments ('Malta archaeology') have provided new insights into the location, nature and preservation conditions of Mesolithic sites in different geological contexts. They are often represented by small concentrations of stone artifacts. In most cases these concentrations are part of larger stone age landscapes separated from each other by thin distributions or isolated occurrences of stone artifacts. Archaeological features associated with occupation (postholes etc.) are generally absent whereas (large clusters of) hearth pits are mainly found outside the settlement areas. Due to their low archaeological visibility, prospecting Mesolithic sites and landscapes is a time consuming task, and this certainly applies to geologically dynamic environments consisting of archaeological remains covered by thick layers of sediment. There is no doubt that low-density sites are often overlooked during borehole surveys or test pit investigations. As a result, we are often dealing with a biased (incomplete) picture of the full range of archaeological phenomena associated with Mesolithic landscapes in a given area.

Partly due to the above-mentioned situation, the assessment of (all archaeologically visible aspects of) Mesolithic human behavior in a specific area and in the context of academic research is often problematic. Moreover, working with incomplete datasets may also have an effect on practical tools specifically used in preventive archaeology, including predictive maps.

This paper examines the potential of buried Mesolithic landscapes in the Holocene Meuse valley in the southeastern part of the Netherlands. What are the characteristics of these landscapes and which criteria determine the archaeological potential? How do we adequately 'translate' this potential into predictive maps? The paper concludes with a short discussion about the role of predictive maps in Dutch preventive archaeology.

2 THE CONCEPT OF ARCHAEOLOGICAL POTENTIAL : AN ANALYSIS OF THE METHODOLOGIES IN ITALY AND ABROAD

Rizzitano, Filippo (Sapienza University of Rome) - Annamaria, Daniele (Sapienza University of Rome) - Fausti, Elena (Sapienza University of Rome)

The planning of public works or public utilities in Italy requires that a Preventive Evaluation of Archaeological Interest (VPIA) must be carried out by a specialist archaeologist. This document assesses the risk of encountering archaeological remains in the project area based on various parameters, defined by the Central Institute for Archaeology (ICA). A crucial factor of this evaluation is the "Archaeological Potential", a key point of the VPIA which indicates the probability of finding archaeological remains in an area, in relation to its geomorphological and historical characteristics. The Potential is expressed through predefined levels, ranging from High to Zero. The aim of this study is to analyze, reconstruct and compare the procedures employed in different countries concerning the Archaeological Potential. For this purpose, a Google Form was distributed to numerous archaeologists working in the field of Preventive Archaeology abroad. Emphasis was placed on identifying the concept of archaeological potential in their methodologies, aiming to discern similarities and differences compared to the Italian approach.

3 ARCHAEOLOGY THAT BURNS. THE DEGREES OF EVALUATION OF ARCHAEOLOGICAL POTENTIAL

Pedersoli, Stefano (University of Sassari) - Caloi, Luca (University of Sassari) - Venco, Veronica (University of Sassari) - Azzalin, Giovanni (University of Sassari) - Magnini, Luigi (Ca' Foscari University of Venice) - Milanese, Marco (University of Sassari)

The theoretical definition of 'Archaeological Potential and Risk' has lasted almost 40 years, at least as far as the Italian context is concerned. From Carver's definitions and theoretical elaborations in 1984 to the latest Ministerial Regulations of 2022, the evolution of the concept in Italy has been continuous and with multiple changes of perspective.

Starting from these theoretical and applicative concepts and based on our experience on three selected case studies (Siligo, Uri and Asinara Island), we propose to implement the quantitative evaluation in addition to the qualitative one. The weighting of information from different sources and methodologies to appropriate degrees of archaeological potential has in fact proved to be very promising in the evaluations of interventions. This has allowed a more detailed analysis of strongly diachronic contexts with a high degree of disturbance due to morphological, vegetational and climatic factors.

The three contexts analysed are part of a landscape characterised by a long occupational persistence, with frequentations from the Neolithic to the Post-Medieval period, including First World War. Through comparative Remote Sensing analysis and ground survey, the archaeological potential, evaluated according to strictly qualitative norms, tends to underestimate in the first instance the real informative scope of the deposit.

In this perspective, the archaeological potential cannot be defined only with the presence or absence of structures. When undertaking a contextual study, it is crucial to consider the density of the archaeological and natural features. To achieve this, we must consider the landscape's geomorphology, as well as the climatic and environmental conditions that have affected the site over time. At the same time, the implementation of archaeological and environmental parameters for the definition of ephemeral sites, such as access routes or seasonal settlements, is significant for the success of the evaluation.

4 CHALLENGES AND OPPORTUNITIES OF ASSESSING THE ARCHAEOLOGICAL POTENTIAL AND QUANTIFYING ARCHAEOLOGICAL RISK AT KHIRBAT ISKANDAR AND ITS ENVIRONS (JORDAN)

D'Andrea, Marta (Sapienza Università di Roma, Dipartimento di Scienze dell'Antichità) - Richard, Suzanne (Gannon University, Erie, PA) - Long Jr, Jesse (Lubbock Christian University) - Forti, Luca (Università degli Studi di Milano, Dipartimento di Scienze della Terra "Ardito Desio") - Zerboni, Andrea (Università degli Studi di Milano, Dipartimento di Scienze della Terra "Ardito Desio") - Deady, Tucker (University of Toronto) - Lanzaro, Nicola (Sapienza Università di Roma) - Cioffi, Carolina (Sapienza Università di Roma, Dipartimento di Scienze dell'Antichità)

Khirbat Iskandar is a mounded site in southern central Jordan. Since 1981, the Archaeological Expedition to Khirbat Iskandar and Its Environs has documented the occupational sequence from Early Bronze I through IV in the excavations on the tell, and evidence from the Palaeolithic, Chalcolithic/Early Bronze Age, the Iron Age, and the Nabatean, Roman and Byzantine Periods in surveys. However, during the past decades, the land around Khirbat Iskandar has been developed for agriculture, impacting the preservation of the archaeological landscape. A modern road likewise cuts through the site, destroying the stratigraphy and exposing ancient architecture, furthering threats of erosion and decay.

Therefore, the Expedition's most recent efforts concentrated on reassessing the archaeological potential of Khirbat Iskandar and its environs, and quantifying archaeological risk in the area with an approach combining: 1) remote sensing analysis and geomorphological survey for evaluating and monitoring landform evolution and changes in time; 2) geoarchaeological investigation to examine the tell-site formation processes and the occupational sequence; 3) pedestrian surveys; 4) urgent documentation and stratigraphic investigations including traditional techniques, photogrammetry, and 3D modelling privileging endangered areas; and 5) preventative measures to avoid further damage, including sustainable remedial conservation according to best practices.

It is of great importance for the sustainability of archaeological research to promote a wider understanding – from the general public to policy makers – that all sorts of archaeological evidence are of equal significance so as to enhance the protection of components that seem less engaging but have huge heuristic potential. It is also becoming increasingly necessary to reconcile research agendas and the need for site monitoring and protection. Moving from these insights, we report on the objectives, results, and opportunities offered by recent emergency activities undertaken at Khirbat Iskandar and discuss challenges in rescue archaeology actions in theory and practice.

5 THEORETICAL AND PRACTICAL DEFINITION OF THE ARCHAEOLOGICAL POTENTIAL OF SICILIAN LANDSCAPE AND PREVENTIVE ARCHAEOLOGY

Ianni', Filippo (Arkeos s.c.; Confederazione Italiana Archeologi - Sicilia) - Giannitrapani, Enrico (Arkeos s.c.; Confederazione Italiana Archeologi - Sicilia; Dipartimento Culture e Società, Università di Palermo)

Archaeological potential concerns the predictability of an area to have hosted past human activities, as well as the grade and quality of preservation of that evidence. It can be evaluated through a multi-proxy approach based on the known archaeological record or the paleoenvironmental and geoarchaeological features of the studied context. The archaeological potential has traditionally been a key issue for landscape studies; its relevance today is increasing within preventive archaeology, with a growing development in the accuracy and innovation of methods. The concept of potential in these two fields, which indeed share methodological and interpretative perspectives, takes on different contours, primarily connected to the scales of analysis. In landscape archaeology, the analysis area should be of medium to large size to acquire sufficient data to read settlement dynamics and the relationship between human communities and nature. In preventive archaeology, there is a reversal of the perspective whereby it is not the landscape at the centre of the analysis but rather the actual public work and its degree of invasiveness to the known cultural heritage and that 'potentially' yet to be discovered. For this reason, the scale of analysis must necessarily be limited, calibrated on the actual spatial dimension of the work subject to verification. Here, we discuss the theoretical and practical definition of the archaeological potential within the context of Sicily based on our direct experience as researchers actively involved in studying the island's prehistory and as professional archaeologists engaged in preventive

archaeology daily. Because of such a double role, we are well aware of the methodological and scientific backwardness affecting the current research on the island. These gaps can be filled only with greater awareness of the digital tools and cognitive processes available today, together with a greater level of multidisciplinary, open data and digitalisation of the archaeological evidence

6 DIFFERENCES AND SIMILARITIES IN THE DEFINITION OF THE ARCHAEOLOGICAL POTENTIAL BETWEEN PLAINS AND MOUNTAINS. TWO CASE STUDIES UNDER ANALYSIS

Fini, Antonio Maria (Sapienza università di Roma) - Sabbatini, Irene (Sapienza università di Roma)

This contribution will analyse the results of the study of archaeological potential applied in two different territories. In the first case, we are in Abruzzo, (Scontrone - L'Aquila, AQ), in a mountainous area heavily affected by modern quarries, which partially destroyed the archaeological palimpsest. In the second case, we are in southern Lazio, in the Agro Pontino (the Ager Pomptinus of the ancients) in the province of Latina, characterised by dunes and coastal lakes, behind which lies a densely populated and cultivated plain, the result of an imposing reclamation project carried out in the 1930s. The area has been subject to systematic territorial investigations over time.

The archaeological potential of an area, i.e. the possibility that it preserves archaeological structures or stratigraphic levels, is calculated through the analysis of a series of parameters applied to the context under study (from the presence of traces of frequentation in ancient times, conditioned by soil visibility, to geomorphological and environmental characteristics in ancient and post-antique times, anthropogenic actions) and constitutes a fundamental predictive tool both in the context of preventive archaeology sites (as in the case of Scontrone) and in the context of research (as in the case of Agro Pontino).

We report the results of our research not only describing the tools and evaluation parameters used but, above all, underlining their different weight in the study of the archaeological potential of the two contexts, also considering how man's action has affected over time.

7 PREVENTIVE ARCHEOLOGY AND DESIGN OF ELECTRICAL WORKS: THE CAPACITY FOR DESIGN MITIGATION OF CONSTRUCTION RISK

Frapporti Battiti Moretti, Michela (Terna SpA) - Calabria, Maria Elena (Terna SpA) - Cirrincione, Roberto (Terna SpA) - Consigli, Simona (Terna SpA) - Macerola, Fabiana (Terna SpA) - Vattimo, Elena (Terna SpA) - Vitale, Simone (Terna SpA)

During the risk assessment phase of the project, which is a crucial step in preparation for the VPIA screening procedure, challenges may arise due to technical and environmental limitations not previously taken into account and also to the lack of data (impossibility of access to the land, absence of archaeological data from bibliography and archives).

Enhancing evaluation and minimizing "construction risk" requires considering design elements that enable "flexibility" that is the ability to absorb changes in location or technology during various project phases. Identifying project indicators is a crucial step in this process.

The inclusion of this flexibility is an essential measure in mitigating design issues in archaeological analyses and evaluations. For each type of work, there are, in fact, a series of technical, technological, construction, and environmental factors, which direct and sometimes constrain the design, determining its location. These factors allow us to identify the so-called "project nodes" as those types of works, or parts of the intervention, that can rarely be modified or re-located due to the technical/technological complexities and/or the importance of an electrical and localization point of view.

These technical-constructive differences determine a different capacity for design optimization in the event of archaeological interferences and a different possibility of resolving them. For project nodes, the construction risk is considered high and must, therefore, be managed as best as possible right from the initial stages of localization and design.

The integrated approach between archeology and design allows us to define a differentiated action strategy for each type of work (overhead power lines, underground cables, or electrical stations), already during the embryonic phases of the design of strategic works.

8 LEVERAGING MACHINE LEARNING IN REMOTE SENSING FOR ENHANCING ARCHAEOLOGICAL IMPACT ASSESSMENT: THEORETICAL CONSIDERATIONS AND FUTURE PROSPECTS

Traviglia, Arianna (IIT) - Giovanelli, Riccardo (IIT) - Poggi, Giulio (IIT)

The integration of machine learning with remote sensing technologies presents a significant opportunity to advance the field of Preventive Archaeology, particularly the redaction of Archaeological Impact Assessment (AIA). Machine learning algorithms offer distinct advantages over visual inspection of the data, enabling the analysis of large datasets

efficiently and accurately. In addition, machine learning can manage complex datasets, which include near-infrared (NIR) and infrared (IR) bands, increasing the detection rate of subtle archaeological features that may elude human observation. Despite its potential benefits, the integration of machine learning needs robust training datasets that accurately represent the diversity of archaeological sites and landscapes. It also may require high specialisation and expensive computational resources. Additionally, the interpretability of such models remains a topic of discussion, as complex algorithms may obscure the rationale behind site identification and classification in archaeological practice.

This paper focuses on the theoretical framework surrounding the application of machine learning algorithms in AIA. In regions like Italy, where the analysis of remote sensing data for AIA is mandatory, machine learning holds immense potential in speeding up the identification and evaluation of archaeological sites. This paper examines the theoretical underpinnings of machine learning in remote sensing, emphasising its potential advantages, disadvantages, and bottlenecks. Presenting case studies and theoretical models, we aim to underline the efficacy of machine learning in boosting the accuracy and efficiency of archaeological impact assessments. Furthermore, we explore prospects for this integration, highlighting areas for further research and development. Thus, this presentation seeks to establish a comprehensive understanding of the theoretical and methodological implications of employing machine learning in AIA. By addressing the main challenges and opportunities associated with this approach, we aim to advance the state of the art in preventive archaeology and contribute to the sustainable management and preservation of cultural heritage resources.

9 THE ARTE PROJECT: FROM THE ARCHAEOLOGICAL MAP TO TERRITORIAL PLANNING

Tadolti, Matteo (Università di Macerata) - Perna, Roberto (Università di Macerata) - Uricchio, Tiberio (Università di Macerata) - Ciuccarelli, Maria Raffaella (Università di Macerata)

The ArTe project coordinated by the University of Macerata which involves numerous State and Regional Bodies, aims to identify new models and tools in order to integrate archaeological data into territorial and urban planning.

The archaeological map of the Province of Macerata, created with traditional methodologies, is the basis for developing, also thanks to the use of artificial intelligence, settlement forecast maps, vulnerability maps and other tools useful for reading the territory in ancient times. These tools, thanks to the collaboration between archaeologists, economists and planners, are the basis of the territorial development projects that the ArTe project aims to develop.

The objective is to provide archaeologists with useful tools and categories to deal with the processes of transformation of the territory, moving from passive protection to active protection, capable of making the needs of protection itself and valorisation interact with the transformation processes. of the territory, with the aim of growth.

10 ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING APPLIED TO AERIAL PHOTOREADING: THE CASE STUDY OF TERNA SPA

Macerola, Fabiana (Terna SpA) - Cirrincione, Roberto (Terna SpA) - Di Palma, Maria Anna (NTT DATA Italia) - Di Tullio, Lorenzo (Terna SpA) - Ferrari, Veronica (Università del Salento) - Gugliandolo, Emanuele (Terna SpA) - Luzzi, Giuseppe (Terna SpA) - Parisella, Giuseppe (NTT DATA Italia) - Tarquini, Emanuele (Terna SpA)

In Italy, the VPIA feasibility assessment is a key aspect of the authorization process for a new infrastructure project, exerting a significant influence on the project's timeline and resource allocation.

One of the primary stages of this study involves analyzing aerial and satellite images to uncover any potential archaeological anomalies. However, this task can be complicated and time-consuming, requiring specialized expertise.

The experimentation conducted by the working group, under the leadership of Terna and with the support of Unisalento and NTT Data, was primarily focused on the engineering and training of an Artificial Intelligence tool, capable of identifying potential archaeological anomalies through the analysis of aerial images. The image analysis process was created and put into action to facilitate and predict the photoreading process, even during the initial stages of the planning, supporting experts in analyzing a specified area and identifying three types of anomalies: damp marks, crop marks, and soil marks.

The main steps of the experimentation were:

- dataset setup, with the acquisition of a large set of orthophotos, to train and evaluate the model validity;
- selection of the algorithm. Based on the type of input data used, a Deep Learning algorithm was selected for image analysis (Transformer-Based Ensemble Model);
- model training. Labels were associated with the images used in the test phase, i.e. information on the presence or absence of archaeological anomalies within the territory under examination. Their analysis allowed the machine to learn and make predictions on new images (supervised method). The outputs were checked and validated by archaeologists;
- model evaluation. The model trained with the test images was run with a new dataset to evaluate its validity.

11 DOES ARCHAEOLOGICAL POTENTIAL NECESSARILY BEGIN WITH POSITIVE DATA? THE WHARP APPROACH

De Davide, Claudia (Akhet srl) - Glarey, Massimiliano (Akhet srl) - Wicks, David (Akhet srl)

In recent years, the digitalization of territorial and archaeological data, and the increased availability of these types of information on-line, have made enormous leaps forward, leading the way to the creation of original new solutions with the help of 'latest generation' information technology.

In this contest it is fundamental to evaluate how these new opportunities can help to create progress in the calculation of archaeological potential as a tool to support not only research but, in particular, the protection of cultural heritage in relation to infrastructural planning.

We believe that, above all in the area of network infrastructure, it is appropriate to approach the specific questions of the maps of archaeological potential themselves and the scales of reference to adopt in their construction, taking in consideration both the type of work to undertake and the needs of the Customer/Client. In this way it would be possible to establish a common language, advantageous to the safeguarding of archaeology across the territory.

Created with this aim in mind, the WHARP project confronts the problem of mapping archaeological potential on a territorial-scale, giving value in particular to negative and landscape data, using archaeological information as a control-mechanism.

In this contribution we present some concrete examples developed in recent years in different territorial contexts in Northern-Italy.

12 CULTURAL RESOURCE MANAGEMENT PREDICTIVE MODELING - AVOIDING PITFALLS USING AI

Clivaz, Emmanuel (AnalyticBase; ArchoBase)

Verhagen (2009) highlighted the limitations of maps based on expert judgment and the need to move toward spatial predictive map. Spatial predictive modeling has nevertheless many pitfalls. Verhagen and Whitley (2020) mentioned the common pitfalls which are biased archaeological input data, predictor variables based on modern-day data sets, the absence of socio-cultural variables, the limitation of temporal resolution and testing done in haphazard ways.

With the archaeological service of the canton of Fribourg in Switzerland, we are currently working on a spatial predictive modeling workflow, using artificial intelligence (XGBoost). I will present the way we handle some of the pitfalls mentioned above and describe how we seek to automatize the whole process, from data entry to the production of predictive maps, in order to be able to retrain the models at constant intervals.

We have developed our models following the principle of increasing complexity, starting with a "Baseline Model" addressing the issue of presence/absence ratios and pseudo-absence ratios. Then moved towards a "Spatial Model" by incorporating the distance to other occupations. Then developed "Spatio-Temporal Models", by contrasting period models to a general model. Finally, developed an "Advanced feature model" that includes socio-cultural variables.

This is a work in progress. In this presentation, I will show how we solved some of the pitfalls along the way and mention the challenges we are still facing.

13 APPLICATION TO BE A DISCUSSANT: MAPPING ARCHAEOLOGICAL HERITAGE IN SOUTH ASIA (MAHSA) PROJECT

Petrie, Cameron (University of Cambridge) - Roberts, Rebecca (University of Cambridge) - GS, Abhayan (University of Kerala) - Hameed, Mohammad (University of the Punjab) - Mushtaq, M. Waqar (Islamic University Bahawalpur) - Prabhakar, VN (IIT Gandhinagar) - Samad, Abdul (Department of Archaeology and Museum, Khyber Paktunkhwa) - SV, Rajesh (University of Kerala) - Singh, Vikas (Banaras Hindu University) - Project, MAHSA (University of Cambridge)

The Mapping Archaeological Heritage (MAHSA) project is working alongside a range of stakeholders to not only document archaeological heritage, but also transform the way heritage is managed at both local and national levels. Pakistan and India each have a rich archaeological heritage due to their being the locus of one of the earliest instances of ancient urbanism. India currently has the largest population globally, and it is increasing at 0.99% per annum. Pakistan now has the fifth largest population globally, and it is increasing at 2.00% per annum, which is the highest rate in South Asia. Despite this rate of population growth, both India and Pakistan still have well under 50% of their populations living in cities, meaning growth is occurring in both urban and rural areas. Urban expansion and the need to engage in extensive and intensive farming creates conflicting pressures on land and essential natural resources.

Archaeological and cultural heritage are factors often overlooked in thinking and planning in discussions about sustainability, but they are often under acute threat due to the expansions of urban areas and agricultural land that accompany population growth. It is arguable that it is imperative that heritage must be thought of as a unique and finite resource that is worth of an equal level of importance in discussions of sustainability (UN SDG 11.4). Through

stakeholder consultations, MAHSA has been working to bring together professionals involved in urban planning agriculture, and heritage to explore current and future prospects for research, monitoring and collaboration within and between these areas of research and policy. As part of the discussions, we hope to develop staggered and realistic future research and policy intervention plans that will foster consideration of each of the three areas in policy and decision making in line with the UN Sustainable Development Goals.

1159 BC_BEFORE CHURCH. CULT BUILDINGS IN ANCIENT MEDITERRANEAN EUROPE. SESSION 1. BEYOND THE THRESHOLD: "INDOOR" CULT-PLACES IN MEDITERRANEAN EUROPE

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Guidi, Alessandro (Dipartimento di Studi Umanistici - Università degli Studi Roma Tre) - Nomi, Federico (Scuola Superiore Meridionale) - Saltini Semerari, Giulia (Department of Anthropology, University of Michigan) - Lehoërff, Anne (CY Cergy Paris Université)

Session format: Regular session

The study of the relationships between religion and archaeology - and specifically our ability to identify evidence for religious activity and associated places of worship in the archaeological record - has progressed considerably in recent decades, thanks not only to the advances in archaeological methodology, but also to the development of theoretical debates in papers and monographs (e.g. Bradley 2005, Fogelin 2007, Kyriakidis 2007).

Here, we will focus on a specific theme, a kind of 'fil rouge' that crosses space and time: the emergence and evolution of cult-places over the centuries in the context of Mediterranean Europe: the aim is to identify the lines of their development at different stages and in different areas of Mediterranean Europe.

Thanks to interdisciplinary research, many features can be identified, not only in terms of the type of structures or objects, but also in terms of organic offerings (seeds, meat portions, skeletons, etc.), with the aim of reconstructing the rituals performed in such places and their changes over time and space.

Papers will deal with the origins and early developments of "indoor" cult-places (natural caves, artificial hypogea, specific structures within inhabited areas, sanctuaries, etc.), conceived in the beginning (probably since Paleolithic) as a kind of chthonic world beyond cave entrances and then progressively realized in built structures. Contributions will range from the Neolithic to the Iron Age. The session will welcome papers addressing the following themes: the theoretical and methodological reflections on the topic of the session, the revision analysis of previous contexts using new methodologies and, finally, the latest discoveries from ongoing archaeological research.

ABSTRACTS

1 NON-UTILITARIAN DEPOSIT PITS OF THE MIDDLE NEOLITHIC, FROM THE MEDITERRANEAN TO NORTHERN FRANCE: PROPITIATORY VOTIVE PRACTICES?

Emmanuel, Ghesquière (INRAP - National Institute for Preventive Archaeological Research)

Non-utilitarian deposits were observed under various forms during the Neolithic, from the Mediterranean coasts to Northern France. Their identification, on an archaeological level, is difficult and varies greatly between authors: the contexts are unclear, and the indications of votive practices are often suspected based on the characterization of inexplicable facts on a technical or functional level. We are not talking here of deposits which could be considered as stocks of valuable objects (large blades, daggers, axes), nor of deposits made in a funerary context (viaticum), but of practices observed in a less conventional framework, often isolated.

Those which have been highlighted present one or more complete ceramics and one or more fragments of grindstones. On the French Mediterranean coast, pits are often built with stones, a practice less used further north. On the other hand, the northwest quarter of France, often presents associations with charred seeds. The best represented period is the Middle Neolithic.

How can we interpret these deposits which do not seem to have any practical utility function? Is it a form of pit playing a supplementary role to these of the burial, in the absence of the body? Is this a form of propitiatory chthonic wor-

ship? And finally, can we compare these deposits to those of other objects, such as for example the pairs of buried overpolished axes cutting edge upwards?

2 THE EMERGENCE OF RITUAL PITS: A CASE FROM THE EPIPALAEOLITHIC CONTEXT OF GEDIKKAYA CAVE IN NORTHWESTERN TÜRKIYE

Sari, Deniz (Bilecik Seyh Edebali University)

The human being initially might not be able to see a chain of causation between the natural threats upcoming without knowing when or how, such as the thunderbolts, earthquakes, floods, volcano eruptions, or animal attacks. In times when environmental and cultural memory had not been formed yet, human beings from different areas reacting similarly in the face of the natural phenomena acknowledged those situations as “supernatural” and he related them to the “beyond” concept so that he has sought a solution through the spiritualism to handle the problems caused by these “supernatural” phenomena.

As the human increases his experience and his knowledge about the mechanism of nature, he might find a way to stand out against the unknown and he also developed various defense systems to handle his fears even though he learned how to get over them. At this very point, wall paintings, statues, cult monuments, burial rituals, and the treated bones of humans and animals become something. We can easily say that the biological fear starting to take a cultural course in time has transformed into a cultural case such as the Ancestral Cult and Shamanism in the latter phases.

This paper aims to discuss the causes and the consequences of the prehistoric rituals and what lies beneath considering the ritual pit been formed around a stalagmite and some group of artifacts from the pit and its context dated to 14500-11200 BC from Gedikkaya Cave in Northwestern Türkiye. Artifacts dating to the Epipalaeolithic suggest links between European Upper Palaeolithic cultural entities and the Pre-Pottery Neolithic of Southeastern Anatolia and Levant displaying a developed culture and complex structure with ritual practices containing symbolism.

3 THE ROLE OF NATURAL CAVES BETWEEN MARCHE AND ABRUZZO FROM NEOLITHIC TO IRON AGE

Pignocchi, Gaia (Scuola di Scienze e Tecnologie - Università degli Studi di Camerino -)

Although Marche and Abruzzo show strong similarities in the pottery production, in particular during the Neolithic (Impressed Ware, Ripoli, Fossacesia) and the Bronze Age (Apennine and Subapennine culture), the use of caves in these two regions is very different in reference to the known funerary and cult manifestations.

From the 1997 Imola exhibition “Waters, Caves and Gods. 3000 years of pre-Roman cults in Romagna, Marche and Abruzzo”, in which Nora Lucentini for the Marche and Vincenzo d’Ercole for Abruzzo had presented unpublished data on the frequentation of caves and their funerary and cultic use in the metal age, other data are added, in particular for the Marches.

In recent years, in fact, I have undertaken a review of the archaeological and stratigraphic complexes in the Frasassi caves (Marche region), which were excavated between the end of the 1800s and the first half of the 1900s, but which, thanks to modern interdisciplinary research and analytical approaches, are revealing data of great scientific interest.

A topic of great interest is the frequentation of natural caves for cultic and funerary purposes, practices that concern the ideological and immaterial sphere and are therefore difficult to identify and understand, but for which there are various clues to hypothesize different uses of caves over the millennia, from Neolithic.

Marche and Abruzzo natural caves are special places and played a particular role as meeting places for local communities or single individuals, but they could be also intercultural meeting places.

The information will be analysed in a diachronic but also synchronic way, to grasp, over time and in the different territorial areas, the specific uses of the single cavities, but also of some groups or “systems” of caves, such as those of Frasassi in the Marche or Fucino in Abruzzo.

4 NATURAL AND ARTIFICIAL CAVES IN CENTRAL TYRRHENIAN ITALY: METHODS OF FREQUENTATION BETWEEN THE ENEOLITHIC AND THE BRONZE AGE

Metta, Christian (Centro Studi di Preistoria e Archeologia)

The Tuscan-Lazian Maremma hosts several natural cavities that show traces of anthropic frequentation from the Eneolithic to the Bronze Age. Through the analysis of the single caves and the comparison among them, it was possible to detect three different uses: the first and most evident one is the funerary use, with the presence of collective burials and very few single burials, the second one is the housing use, meant as seasonal and/or occasional frequentation maybe related to pastoral activity, while the third one is the most difficult to determine, being represented by the cult use of caves, where various kinds of rituals are performed. Another interesting aspect regards the modes of frequen-

tation, showing temporal and spatial differentiation in the exploitation of the cavities: during the Eneolithic the most frequented caves are situated in Tuscany with only some sporadic use of the Lazian ones, while during the subsequent phase the use of the Lazian caves increases with the abandonment of the Tuscan ones.

In the Copper and Bronze Ages, both natural and artificial caves were used: funerary structures imitating caves (oven or chamber tombs) were created, but sometimes some of these underground structures were intended for ritual practice. Only in the Late Bronze Age did we witness a change, natural caves were no longer used, but places of worship were created within the settlements inside artificial caves, which reminded, at least conceptually, the natural ones. Some traits seem to characterize a process of “artificialization” and imitation of the natural sacred place in the Etruria of the metal age, from the natural sacred place (water source, mountains and caves for example) to the built one.

5 FROM CAVES TO HUTS... SACRED THRESHOLDS?

Nomi, Federico (Scuola Superiore Meridionale; Associazione ORTA) - Truffi, Michele (Dipartimento di Studi Umanistici - Università degli Studi Roma Tre; Associazione ORTA) - Militello, Pietro (Dipartimento di Scienze Umanistiche - Università di Catania) - Guidi, Alessandro (Dipartimento di Studi Umanistici - Università degli Studi Roma Tre)

During the Late Bronze Age in central and southern Italy, there is a discernible decline in the practice of utilizing natural caves for ritual purposes. This trend aligns with the concurrent emergence of open-air cult sites, indicating a shift in religious beliefs. Simultaneously, one can observe the existence of structures that appear to serve a purpose distinct from mere habitation.

In 2015, Charlotte Potts wrote an article with the evocative title ‘Sacred Huts’, wherein she precisely explored the distinguishing characteristics that could differentiate structures used for cult activities from typical dwellings. Her examination involved several case studies from the mid-Tyrrhenian area.

In this communication, we endeavour to address this issue by broadening the analysis to encompass the primary settlements of peninsular Italy and Sicily. Our aim is to meticulously identify potential cult huts or structures designed for similar purposes. Additionally, we seek to illuminate the parameters that could either substantiate or refute such attributions.

A varied panorama emerges from the study, with buildings that can be interpreted as places of worship and others in which there are only a few features indicative of the performance of activities of a ritual nature, and for which only further analysis will be able to provide clearer answers in the future.

6 PLACES OF WORSHIP IN LAND AND WATER. BRONZE AGE HOARDS IN THE MEDITERRANEAN IN THEIR EUROPEAN CONTEXT

Lehoerff, Anne (CY Cergy Paris University)

Does the act of religion require a particular place, a sacred space? And what form can this reality take? The notion of monument is often associated with the practice of worship. But what if we were to look at the question in a different way? Bronze Age hoards in the Mediterranean and the rest of Europe are now a recognized phenomenon. There are many different interpretations, depending on the number of objects, their nature and where they were found. Sometimes they are simply temporary “hiding places” for metalworking crafts. However, even in the case of fragments, internal logics suggest that these assemblages have a ritual and cultic dimension. The act of burial and engulfment also belongs to the repertoire of the religious gesture, embodied both by these carefully chosen objects and by the place where the ceremony takes place. This presentation will explore the possible perception of this religious dimension in the Bronze Age, using examples of Mediterranean hoards put into perspective on a European scale.

7 UNRAVELING THE BUNDLE: TRACING ANCIENT CULTS IN ITALY’S IRON AGE THROUGH CONTEXTUAL ANALYSIS OF RITE SPACES

Tirloni, Ilaria (independent researcher)

It is challenging to identify the traces of cults practiced by the peoples living in Italy during the Iron Age, particularly in the early Iron Age, due to the lack of evidence and written sources.

The focus of this paper is the analysis of certain cult places where chronological continuity can be discerned, especially in non-built ritual spaces that are clearly defined for cult purposes.

Starting from reflections on how to recognize ritual space, I sought to apply a new investigative method that begins with analyzing the entire context and extends it to the sphere of cults. Thus, I aimed to reevaluate the relationships among artifact classes and reinterpret some of them, following a line that demonstrates a diachronic development of certain elements identified as “cult markers.” This selection was made through the analysis of key studies that could be more representative, yet simultaneously encompass different typologies, ranging from caves (Rocchicella di Mineo,

Grotto Pertosa) to well-known cult places from the classical period (Megara Hyblaea, Saturo). Special attention was given to Sicily, which is replete with cult places dedicated to chthonic deities, Demeter, and Kore.

8 EXPLORING SACRED RITES ON THE CELTIC PERIPHERY: THE SANCTUARIES OF CASTREJÓN DE CAPOTE AND EL CERRÓN DE ILLESCAS

Ruano, Lucía (Universidad Complutense de Madrid) - Berrocal Rangel, Luis (Universidad Autónoma de Madrid) - Fernández-Götz, Manuel (University of Edinburgh) - Sánchez de Oro, Pablo (Universidad Autónoma de Madrid)

The hillfort of Castrejón de Capote stands out as one of the southernmost Celtic settlements in Europe. It served as a significant hub for the Celtici of the Beturia region, believed to have migrated to the area during the late 5th and early 4th centuries BC. Extensive excavations conducted at the site in the late 1980s and early 1990s unearthed domestic structures, the fortification system, and a central sanctuary. The latter is a rectangular structure open to the main street and elevated on a podium, in the centre of which a stone table was located. Numerous finds related to communal feasting were documented, including remnants of bonfires and animal bones, as well as a collection of over a thousand artefacts. The evidence suggests the practice of public ceremonies with meat offerings, alcoholic libations, and the burning of aromatic and psychotropic substances.

In this paper, we present an overview of these findings, enhanced by a collaborative research project launched in 2023 with the objective of re-examining the archaeological record using novel methodologies and theoretical frameworks. Through new archaeological interventions, this project also seeks to deepen our comprehension of the architecture, material culture, and spatial organisation within this site on the southern periphery of the Celtic world. Our focus lies in comparative analysis with other structures within the hillfort itself, as well as in exploring potential architectural parallels in other cultural contexts. In particular, we will focus on the comparison to the sanctuary documented in the Carpetanian settlement of El Cerrón de Illescas. The analysis not only enhances our understanding of religious practices during the Late Iron Age, but also sheds light on the dynamics and symbolic significance embedded within ritual spaces across diverse cultural landscapes.

9 PAGANISM IN PRACTICE: AN ETHNOARCHAEOLOGICAL EXPLORATION OF SACRED SITES, RITUALS, CEREMONIES, AND BELIEFS IN RURAL ALBANIA

Agolli, Esmeralda (Department of Archaeology and Culture Heritage, University of Tirana)

In Albania, despite the prevalent adherence to four monotheistic religious traditions, namely Sunni and Bektashi Islam, Roman Catholicism, and Eastern Orthodox Christianity, there exists a noteworthy presence and acceptance of alternative pagan rites, ceremonies, and cultic practices. These manifestations of pagan belief systems, characterized by their diverse forms and expressions, enjoy a considerable degree of popularity and participation among individuals, even those identifying with Islam or Christianity, who readily engage in such practices during times of exigency and disillusionment. Often, believers avail themselves of opportunities to partake in rituals within settings perceived as sacred, be they designated tombs, revered locations, or natural features endowed with sanctity.

This paper undertakes an analysis of empirical data sourced from various sacred structures situated across rural Albania, purposefully constructed to serve sacred functions. Through the utilization of oral narratives procured from local informants, the study delineates the typological classifications of these structures, delineating their origins, the associated miracles attributed to them, and the temporal expansion of their popularity. By means of site visits and participation in rituals enacted within these venues, individuals harbor sentiments of hope and anticipation, yearning for resolutions to life's tribulations.

The primary objective of this inquiry is to elucidate the behavioral tendencies intricately linked with paganism, manifesting in the form of rites, ceremonies, and tangible architectural features, thereby facilitating a comprehensive analysis of the multifaceted dimensions inherent within an active ethnographic context. The discernment of how human conduct intersects with diverse belief systems, encompassing spiritual entities and transcendent powers that traverse realms beyond human comprehension, holds considerable significance in unraveling the complexities underpinning societal dynamics.

1160 INTERCULTURAL CONTACTS WITHIN THE BALTIC SEA REGION FROM PREHISTORY TO THE EARLY MIDDLE AGES

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Niedziółka, Kamil (Institute of Archaeology, University of Gdańsk) - Pappmehl-Dufay, Ludvig (Linnaeus University)

Session format: Regular session

Archaeological data clearly confirm that people living on the Baltic coast have been crossing this sea and establishing contacts with those on the other side since the Mesolithic. This led to the formation of complex networks of supra-regional contacts centred around the Baltic Sea. Depending on the period under study, these contacts took on different forms and intensities, although they practically have never ceased completely.

Unfortunately, the current state of research on these issues is heavily deformed by contemporary and mundane factors such as national or linguistic borders. This is often due to a lack of awareness of the similarities between the areas on the other side of the Baltic Sea, as results from individual countries are traditionally published in national languages. Their range is thus considerably limited. The same applies to conferences, some of which also have a limited reach due to the lack of wider international research networks.

The aim of this session will be to bring together researchers involved in the study of the past of the societies inhabiting the Baltic Sea coasts and islands. We would like to discuss issues related with identifying and expanding our knowledge of trans-regional contacts between these areas. We would also like to establish a network of academic cooperation focused on this wide range of topics. Let's simply get to know each other!

ABSTRACTS

1 AROUND THE BALTIC AND BEYOND: TRANS-BALTIC CONTACTS THROUGHOUT PREHISTORY AND EARLY HISTORY

Niedziółka, Kamil (Institute of Archaeology, University of Gdansk)

Events along the Baltic coasts have repeatedly influenced the rest of Europe. One of the most significant examples is the migrations of the historical Gothic tribes, who moved from southern Scandinavia to the southern Baltic coasts at the beginning of our era. A few hundred years later, they contributed significantly to the collapse of the western part of the Roman Empire and a complete 'remaking' of the political, economic, and ethnic scene in then Europe. Moreover, this was not the only instance where events on the Baltic Sea later affected large parts of Europe in various periods. The system of long-distance contacts, associated with the influences of the Nordic Bronze Age elites, covered a large part of the Baltic Sea coast and extended well beyond this region during the Bronze Age. On the other hand, during the Early Iron Age, the phenomenon of Pomeranian facial urns emerged on the southern Baltic coasts, which later spread over extensive areas of Central Europe in a relatively short period of time. These and many other aspects dictate that the Baltic region should not be perceived as a remote and insignificant periphery but as an area where many very important processes had their origin.

From this perspective, it is high time to expand beyond the current research scheme of this region, which is based mainly on the analysis of the dispersion of specific groups of artifacts. It is also worthwhile to focus on analyses of past landscapes (using modern tools such as remote sensing and geophysics) as well as paleoenvironmental studies (paleontology). Here, however, cooperation between researchers from various countries bordering the Baltic Sea is crucial. This will help to remove political constraints (since most literature is still produced in national languages) and broaden our current perception of the past of the entire region.

2 ONE PLACE, DIFFERENT PRACTICES: POTTERY PRODUCTION IN ABORA I NEOLITHIC SETTLEMENT

Haferberga, Vanda (University of Latvia)

Abora I Neolithic settlement is one of the most known lake Lubāns wetland sites in the Eastern Baltic. During the archaeological excavations, which started in 1963 and periodically continued until today, besides the settlement context 62 burials within it was also discovered. Some of these burials were identified as ones from Corded Ware Culture. Traces from this culture were also discovered in the settlement context. Next to local pottery styles such as porous and Lubāns type, the non-local Corded ware was also distinguished. The aim of this paper is to distinguish techno-cultural aspects of Neolithic pottery craft in the Abora I settlement. In order to reach the aim several methods were used: macroscopic evaluation, ceramic petrography, Wavelength Dispersive X-Ray fluorescence spectroscopy.

The paper was prepared within the Latvian Council of Science funded project “The environment and early farming of the Abora Neolithic settlement in lake Lubāns wetlands” (project no. lzp-2022/1-0300).

3 NEW EVIDENCE OF LATE BRONZE AGE CIRCUM-BALTIC CONTACTS FROM KUKULIŠKIAI SITE, LITHUANIA

Urbonaitė-Ubė, Miglė (Klaipėda University) - Pranckėnaite, Elena (Klaipėda University) - Minkevičius, Karolis (Klaipėda University) - Ubis, Edvinas (Klaipėda University)

The hilltop settlement of Kukuliškiai (Klaipėda district) is the only single-layer Late Bronze Age settlement (883-403 cal BC) in the Lithuanian marine landscape, located only a few hundred metres from today's seashore. Systematic research has been carried out since 2017 and a large amount of material has already been collected. Thorough analyses of artefacts, ecofacts and palaeoenvironmental factors have revealed evidence of cultural contacts with distant places in the Baltic region. Interdisciplinary approaches have provided new insights into the internal and external structure of settlements and specific economic features.

The Late Bronze Age in the Baltic region is a period of great changes in social, cultural and economic fields, influenced by long-distance interactions between different areas. The influence can be seen in agricultural practices, pottery making, bronze smelting and the use of amber. This presentation aims to show the possible routes of cultural contacts and how they developed in different parts of the prehistoric community of Kukuliškiai during a Late Bronze Age.

4 WHITE SHORES, AND BEYOND... MATERIAL TRACES OF TRANS-BALTIC CONNECTIONS FROM MIGRATION PERIOD ÖLAND, SWEDEN

Papmehl-Dufay, Ludvig (Linnaeus University)

The Baltic island of Öland, located off the east coast in SE Sweden, is extremely rich in historical and archaeological monuments and finds. Remains from the Iron Age are especially numerous, including countless cemeteries, more than 1000 still visible stonehouse-foundations and at least 16 ringforts. A signature feature of the migration period (c. AD 400-550) on Öland are the numerous finds of 5th century Roman gold solidi, usually interpreted as testimony of mercenaries returning from expeditions to the Roman empire. While large efforts have been spent on understanding the solidi and their links to places and events on the continent, little is still known about the routes and networks enabling these travels. In this paper, the migration period archaeological record from Öland will be viewed in a trans-Baltic perspective, tracing evidence for contacts across the Baltic Sea and discussing some potential aspects of the travelling routes further to the south.

5 'BOTTOM-UP' OR 'TOP TO BOTTOM' - TRACKING VIKING AGE WHETSTONES FROM EIDSBORG, NORWAY IN THE BALTIC SEA REGION

Zawalska, Judyta (Museum of Cultural History, University of Oslo) - Loftsgarden, Kjetil (Museum of Cultural History, University of Oslo)

All through the Norwegian Viking Age (800-1050) large amounts of whetstones were extracted from quarries at Eidsborg in the inland of Norway and transported by local waterways towards the coast, where it set off on a journey over the North Sea, Baltic Sea and beyond. To sites like Ribe and Aggersborg, Denmark, Hedeby, Germany and Wolin, Poland, where large quantities of whetstones have been found. Our paper will explore material from selected sites along the Baltic Sea and its connection to the Eidsborg quarries. Finds, will be reflected upon, from the perspective of context (trading and burial sites, settlement areas), functionality (whetstones, touchstone), and symbolic use (pendants, sceptres). The main objective in tracking whetstones will be to explore the connection and dependencies between extraction structures (quarries, organized production), exchange structures (transportation, long distance distribution) and the beneficiaries of this exchange. Highlighting radiocarbon dates from selected sites will help in better understanding of the phases of production and export, from its beginning, throughout the peak and afterwards the decline. The recognition of Eidsborg whetstones at archaeological sites outside Norway was already confirmed by geochemical analysis in the 1980s. Since then, the number of sites with whetstones, many likely originating from Eidsborg, have increased. There is still, however, questions unanswered and knowledge unexplored about the people that stood behind this bold idea and took upon a task that contributed to expansions of Vikings far from their homeland. We will try to fill in some of those gaps.

6 NEW PERSPECTIVES ON IRON AGE RINGFORT LANDSCAPES IN ÖLAND, SWEDEN BASED ON UAV ALS/LIDAR APPROACHES

Marczewski, Maciej (GLESUM Archaeological Company, Poland) - Wroniecki, Piotr (Montefortino Prospection & Digitalisation, Switzerland) - Papmehl-Dufay, Ludvig (Linnaeus University, Sweden) - Niedziółka, Kamil (Institute of Archaeology, University of Gdańsk)

The results presented are part of the ongoing research program “Crisis, Conflict, and Climate: Societal Change in Scandinavia 300-700,” led by Stockholm University. The project focuses on Iron Age ringforts on the island of Öland in Sweden, constructed in the 4th and 5th centuries AD. These structures are notable examples of stone architecture in Northern Europe's Barbaricum, primarily consisting of circular defensive formations with densely packed buildings inside.

Most of these strongholds were abandoned around 600 AD for reasons yet unknown, with some undergoing redevelopment during the Middle Ages. The usage and abrupt cessation of these sites align closely with the cultural shifts of the Germanic Iron Age/Migration Period in the Baltic Sea region.

This presentation will highlight findings from surveys conducted at 14 ringfort sites in 2023 and 2024, employing Airborne Laser Scanning (ALS) technology and Unmanned Aerial Vehicles (UAV). The objective was to document and explore the complex earthworks identified as ringforts or potential ringforts, along with their immediate surroundings and related features. This effort laid the groundwork for future project phases, such as geophysical measurements, geoarchaeological surveys, and excavations by deploying novel capabilities of UAV-acquired 3D topographic data through archaeologically oriented field methodologies.

The processed data, including point cloud (georeferencing, noise removal, classification) and raster processing, resulted in the creation of archaeologically viable Digital Terrain Models and Digital Surface Models. A variety of visualization techniques, including Compviz, terrain and slope shading models, and 3D representations, aided in interpreting the results. Advanced algorithms helped identify anomalies, providing a comprehensive view of the landscape.

7 SAAREMAA AND ÖLAND - CONTACTS OVERLOOKED? 12TH-13TH-CENTURY STONE RINGFORTS ON BALTIC ISLANDS

Mägi, Marika (Foundation Osiliana / Tallinn University)

Prehistoric contacts between the biggest islands in the Baltic Sea – Gotland (Sweden) and Saaremaa (Estonia) – are recorded both in archaeological and historical sources. Much less is known about interaction between Saaremaa and Öland, a Swedish island further away when looking from the East. In the Viking Age, all three islands formed a part of an intensively used trade route over the Baltic Sea, which connected southern Scandinavia with Eastern European river systems.

The last years' archaeological research has pointed to intensive prehistoric and medieval communication not only between Saaremaa and Gotland, but also between Saaremaa and Öland. The speech here introduces the results of archaeological and geophysical studies at some of the biggest Saaremaa hillforts that possess remarkable similarities with their analogues on Öland. These were ringforts with 7-8 m high ramparts of limestone, re-built at the place of an earlier fortification in the 12th century, and staying in use throughout the 13th century. Ringforts on both islands had buildings inside and outside the main rampart, and additional stonewalls surrounding them. The best-known examples on Öland are Eketorp and Gråborg. From the five Saaremaa ringforts of this type, in this speech Valjala has been chosen as one of the currently best investigated examples.

The fortification structures, function and localisation of Saaremaa's ringforts will be discussed in comparison with similar fortifications on Öland. As indicated by the archaeological evidence along the eastern coast of the Baltic Sea, as well as by few medieval written sources, direct contacts between these two islands seem to have been greatly overlooked so far.

1161 HERITAGE TALES: PARTICIPATORY APPROACHES TO HERITAGE MANAGEMENT AND COMMUNITY ENGAGEMENT

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Fábíán, Szilvia (Hungarian National Museum, Budapest) - Hadji, Athena (DIKEMES - College Year in Athens) - Michelic, Sanjin (Museum of Arts and Crafts, Zagreb) - Pace, Giuseppe (CNR - Institute for Research on Innovation and Services for Development) - Pagano, Fabio (Archaeological Park of Campi Flegrei, Pozzuoli)

Session format: Regular session

ICOM's new 'Museum Definition' was issued in 2022. Although many key points remained seemingly the same, there is a significant change in the emphasis on social components, such as diversity, accessibility, and inclusivity, which is markedly different from the previous 2007 definition. This approach builds substantially on the aims and objectives put forward in the Faro Convention as a seminal document discussing the democratisation of appreciation, access and management of cultural heritage by promoting the idea of shared responsibility within a broader heritage community. Due to increased public activities, museums are increasingly committed to becoming more accessible, friendly and inspiring places, although several challenges may limit such efforts.

For instance, museum representations of cultural heritage may not accurately reflect the diversity and complexity of the local community due to a lack of representativeness or accessibility to the cultural life of certain groups. These problems require constant efforts by museum institutions to ensure that museums are genuinely inclusive and representative of their local communities.

The proposed session invites contributions that analyse theoretical concerns and, mostly, case studies of good practices in heritage management that demonstrate how these efforts contribute towards building local communities and supporting positive social change, focusing, among others, on the following:

- How can museums or other cultural institutions provide a context for developing community consciousness around specific archaeological sites and these networks /and thematic routes?
- Which methods can be used for community building for different target groups and stakeholders, and how do these efforts contribute towards supporting positive social change?
- The (in)adequacy of a conventional understanding of heritage for an increasingly challenging 21st century.
- Contested heritage: what happened to inclusivity?
- The priority of visual qualities: homogeneity vs. diversity in heritage interpretation.
- Cultural tourism in rural and urban areas: excluding residents.

ABSTRACTS

1 SHAPING NARRATIVES: BRIDGING SOCIETAL GAPS AND REDEFINING ARCHAEOLOGICAL RELEVANCE THROUGH VISITOR-CENTRIC APPROACHES

Frascella, Selene (University of Barcelona; Italian Institute of Technology)

The new museum definition (ICOM 2022) has officially recognised accessibility, inclusion and community participation as constituent elements of this institution. However, for museums, especially archaeological ones, making these aspects of their nature effective can be challenging as they are often perceived as elitist and distant places, lacking social relevance and function. But how can this situation change without understanding how the relationship between the audience and heritage develops through the mediation of the exhibition? To contribute to answering this question, this paper presents the results of a non-intrusive observational analysis conducted on the audience of the National Archaeological Museum of Taranto (Italy). The research aims not only to show visitors' real use of the museum and the tools provided but, above all, how these convey the transmission of archaeological messages and influence the visitor's experience and relationship with heritage and archaeology. The results suggest the need to consider the impact of architectural space on the visual perception of visitors, to find a balance in the number of objects on display, to adapt texts in form and content to the needs of a non-specialist audience, and to reward and emphasise visual communication. In conclusion, it will be seen that considering the visitor's perspective in defining these aspects can contribute to an effective transmission of the archaeological message, the development of community archaeological awareness, the redefinition of the social relevance of museums, and the fulfilment of their accessible and inclusive nature.

2 HERITAGE TAKEOVERS - DYNAMICS OF THE COMMUNITY INVOLVEMENT IN ARCHAEOLOGICAL HERITAGE OF STYRIA (AUSTRIA)

Mele, Marko (Universalmuseum Joanneum) - Porod, Barbara (Universalmuseum Joanneum) - Modl, Daniel (Universalmuseum Joanneum) - Kiszter, Sarah (Universalmuseum Joanneum) - Peitler, Karl (Universalmuseum Joanneum)

The archaeological research in Austrian Styria has a long tradition starting in the 19th century. While being mainly in the hands of local priests, teachers, entrepreneurs and other figures interested in local history for the better part of the 19th century many sites have been discovered that still feature prominently in regional history, like the Roman municipium of Flavia Solva. Others, like the Early Iron Age sites of Großklein and Strettweg, are well known in the scientific community to this day. When research institutions like the Universalmuseum Joanneum, the Natural History Museum Vienna, the Universities of Graz and Vienna, the Austrian Academy of Science, the Austrian Archaeological Institute and the Federal Monuments Authority took over in the last two decades of the 19th century those ties to the local population were severed. Only in recent decades have local museums as well as private firms and associations taken over many aspects of research, preservation and presentation of archaeological sites. Researchers from different institutions have acknowledged the significance of contact, relationships and cooperation with locals. While each site has different dynamics in community engagement it always depends on engaged persons interested in local archaeology and history. The prominence of the site, the history of research and presentation, and the economic capacities of the community are far less important in comparison. Two different regions of Styria, southern Styria and Upper Styria will be discussed in detail. The Joanneum was actively involved in research as well in the preservation and interpretation of archaeological heritage in the regions. Hand in hand with the research engagement the work with the communities was an essential part of the activities. This involvement of communities resulted in different levels of success in the management of heritage by communities and the quality of interactions between those communities and their museums.

3 TRANSFORMING VISIONS: A COMPARATIVE STUDY OF PREHISTORIC SITE MUSEUMS IN CHINA

Yang, Miao (University of Cambridge)

This study conducts a comparative analysis of the development and evolution of prehistoric site museums in China, in the context of the new 'Museum Definition' issued by the International Council of Museums (ICOM) in 2022. This definition underscores the importance of social components such as diversity, accessibility, and inclusivity, representing a significant departure from earlier museum conceptualizations. By examining three prehistoric site museums established from the 1950s to the present, this research aims to investigate their adaptation to changes in exhibition methods, community engagement, and socio-economic impacts, reflecting these evolving standards.

Using a mixed-methods approach that encompasses historical review, case study analysis, and comparative research, this study incorporates a literature review, field observations, and interviews to obtain comprehensive insights. It delves into the progression of exhibition designs, the incorporation of technological advancements, shifts in heritage interpretation strategies, and the introduction of interactive experiences. Furthermore, it scrutinizes the interaction of museums with local communities, their influence on cultural tourism and economic development, and the strategies devised to address challenges.

The expected outcomes are to uncover the ways in which prehistoric site museums in China have redirected their primary focus, thus becoming more diverse and responsive to public needs. By shedding light on the development trajectories of these institutions, the research seeks to contribute valuable recommendations for future practices in heritage management and museum studies. It aims to identify limitations and propose directions for further research, enhancing our understanding and approach to preserving and interpreting prehistoric sites.

4 EVALUATING COMMUNITY INTERACTIONS AND HERITAGE PERCEPTION BY COMPARING TWO ARCHAEOLOGICAL SITES IN MENORCA (BALEARIC ISLANDS)

Pastor Pérez, Ana (Grupo de Investigación Gestión del Patrimonio Cultural. Universidad Complutense de Madrid) - Castillo Mena, Alicia (Departamento de Prehistoria, Historia Antigua y Arqueología. Grupo de Investigación Gestión del Patrimonio Cultural. Universidad Complutense de Madrid) - Pérez González, Elena (Grupo de Investigación Gestión del Patrimonio Cultural. Universidad Complutense de Madrid) - Benítez de Lugo Enrich, Luis (Departamento de Prehistoria, Historia Antigua y Arqueología. Grupo de Investigación Gestión del Patrimonio Cultural. Universidad Complutense de Madrid) - Corpas, Nekbet (Grupo de Investigación Gestión del Patrimonio Cultural. Universidad Complutense de Madrid)

Archaeological heritage is one of the fundamental cultural resources of the Mediterranean and the island of Menorca (Spain), as well as a key element in the construction of local identities. There are numerous archaeological sites on the island, each with its own management and exploitation system that presents multiple models for analysis. However, there is a scarcity of perception studies that incorporate the viewpoints of different stakeholders and users. To address this gap, in 2023 we carried out a comprehensive contextual and ethnographic study of two iconic sites: Naveta des

Tudons and Torre d'en Galmés. The assessment of the site's museography focused on narratives and accessibility, and it was combined with a general public survey framed with visitors' impromptu interviews on site and local community and expert focus groups. In this communication we will discuss how the analysis of findings lead to specific outcomes related to better implementation of practices of social inclusion and the formulation of future sustainable-led initiatives aimed at improving the economic, scientific, and social aspects of heritage management and exploitation.

5 JOURNEY OR DESTINATION: HUNGARIAN NATIONAL MUSEUM'S ATTEMPTS AND GOOD EXAMPLES TO PROMOTE ARCHAEOLOGICAL HERITAGE VIA THEMATIC CULTURAL ROUTES

Pálinkás, Adrienn (Hungarian National Museum) - Fábíán, Szilvia (Hungarian National Museum) - Czifra, Szabolcs (Hungarian National Museum)

Besides the constant fight for public interest in museums, there is a long-lasting debate amongst museum professionals concerning the role of museums – whether they should be more education or leisure-oriented. The new 'Museum Definition' (finalised by ICOM in 2022) also changed the emphasis on social components, in line with the 2005 Faro Convention as a seminal document discussing the democratisation of appreciation, access, and management of cultural heritage by promoting the idea of shared responsibility within a broader heritage community.

These challenges require constant efforts by museum institutions to ensure that museums are genuinely inclusive and representative of their local communities. On the one hand, thematic cultural heritage routes can be good examples. They are connecting the objects (stored in the museums) with the archaeological sites where they come from. On the other hand, these cultural routes can stimulate scientific research, be a living part of the local communities and offer an economic and social break-out point for rural areas.

This paper presents solutions to the abovementioned challenges as examples of good practice by the Hungarian National Museum. As a case study, the Museum's presentation focuses on promoting the archaeological heritage on regional, national and transnational level. The presentation showcases all the attempts to connect HNM's exhibition places and surrounding communities through museum's pedagogical and andragogic programs, indoor guided tours and field trips, and workshops and conferences.

But this is not the destination; it is the start of a long journey towards the audience's involvement and finding more creative solutions for promoting archaeological heritage. These principles cannot be executed successfully without market research and identifying museum visitor expectations, which this paper attempts to do. To fulfil these expectations, thematic routes proved to be useful in creating a memorable experience.

6 THE BORDER AS THE "BASEMENT" OF THE IDENTIFICATION OF VALUE. THE CASE OF THE CAMPI FLEGREI ARCHAEOLOGICAL PARK (ITALY)

Pagano, Fabio (Archaeological Park of Campi Flegrei)

A particular role gives to the Archaeological Park of Campi Flegrei the responsibility of 26 sites spread across a large territory near Naples. The dimension of the Park is punctiform and widespread. It extends over the territory of five municipal administrations and is part of a unique context characterized by intense volcanic activity. The theme of the border, therefore, is crucial considering the heritage characterization given to the Park, not a single and well-defined territory, but different areas delimited by respective borders that separate and, at the same time, connect the places of the Park with the urban and social articulation of the territory.

The strategic plan of the Park tends towards the most concrete form of self-determination precisely in interaction with the territory and with the community. The Phlegraean landscape represents an environmental context with a precise anthropological/cultural typicality, the result of a social landscape also in search of an identity, after the disillusionment experienced in the aftermath of the crisis of the industrial sector on which development had been bet territory after the Second World War.

The archaeological remains represent a formidable tool for understanding the Phlegraean landscape, in its different and multifaceted components, starting from the submerged and emerged craters and the system of the highlands-acropolis. For this reason the Park has defined and is adopting its own strategy in working on material and immaterial interconnections, encouraging the perception of its own identity precisely in the dialectic of the border.

The development strategy and management model of the Park have tried to shape themselves on the territory (environmental and human) tending towards the inclusion and integration of projects, ideas, programs and activities, taking advantage of the interstitial spaces and trying to outline compatible directions and sustainable with and for local realities.

7 THE ARCHAEOLOGICAL MUSEUM "ARISTIDE GENTILONI SILVERJ" OF TOLENTINO: FROM THE 19TH CENTURY COLLECTION TO INCLUSEUM

Perna, Roberto (Università di Macerata) - Giaconi, Catia (Università di Macerata) - Spagnuolo, Michele (PlayMarche srl) - Xavier de Silva, Ludovica (Università di Macerata) - Del Bianco, Noemi (Università di Macerata) - D'angelo, Ilaria (Università di Macerata)

The Archaeological Museum of Tolentino is the result of the excavations and studies carried out by Count Aristide Gentiloni Silverj at the end of the 19th century. Despite the Count's pioneering approach to cultural heritage, until recently, the Museum has kept a traditional way of displaying its collection that mostly respected the founder's work.

The project carried out by the University of Macerata and PlayMarche in collaboration with the Municipality of Tolentino has aimed to improve the storytelling, inclusivity, and accessibility of the Museum.

While stressing the importance of Gentiloni Silverj's work for the knowledge of prehistoric and Picene Tolentino, we have worked on the storytelling of the collection, improving its contextualisation by implementing content to build a path through the Picene and Roman periods in Tolentino and adding illustrations and experimental archaeology reconstructions to shed a light on those aspects of the ancient culture and customs that were more difficult to communicate to non-experts.

In the same direction, we worked on the accessibility of information content through co-design activities with associations of people with disabilities. To this end, solutions have been implemented to improve the museum visit of people with intellectual disabilities and sensory disabilities through the design of an integrated system, enabling the different museum visitors to customise their visit, by selecting, even before entering, the tour best suited to their needs and interests.

8 LIBYAN PERSPECTIVES IN THE ARCHIVE OF THE BRITISH INSTITUTE FOR LIBYAN AND NORTHERN AFRICAN STUDIES

Vitale, Valeria (University of Sheffield) - Crowe, Felicity (British Institute for Libyan and Northern African Studies) - Furjani, Reem (Scene)

The British Institute of Libyan and Northern African Studies (BILNAS), in collaboration with the University of Sheffield and Libyan partners, is running an archive engagement project for people in Libya and the Libyan diaspora.

The BILNAS archive mainly comprises records generated by 20th century British archaeological expeditions in Libya, and it has many images showing Libyan archaeological sites and built heritage. But while Libyan antiquities have a prominent role in the archive, the stories of the people living in Libya around those antiquities are often excluded. When the archival material does glimpses of 20th century Libyan culture and everyday life, these often go undescribed in the archive catalogue.

As a first step to gaining a more inclusive view of Libyan heritage and to move towards a more participatory approach to curating the archive, we are delivering a series of remote sessions in Arabic and English, using digitised photographs from the archive to spark discussions with attendees. Before sessions, attendees are invited to annotate the images, adding personal memories and new interpretations. Session discussions then aim to explore the comments and stories in more depth. Each session has a different theme, for example Libyan clothing and its connotations, people's experience of archaeological sites, and identifying Libyan archaeologists in images. During these sessions we are also consulting on how we can make the archive and its catalogue more accessible for people in Libya, for example by adding new keywords and perspectives in English and Arabic. We will discuss the project, what worked and what didn't, and hope to hear feedback from others interested in making heritage more inclusive.

This project is funded by the British Academy and The National Archives.

9 CURATING COMMUNITIES' PAST: DIGITAL APPLICATIONS AND CROWDSOURCING

Lampada, Despoina (Time Heritage) - Kamara, Aphrodite (Time Heritage) - Papakonstantinou, Marietta (Time Heritage) - Pouloupoulos, Vasileios (University of the Peloponnese)

Heritage professionals have established that bottom-up approaches to heritage curation, interpretation and enhancement are usually more long-lasting, as local communities undertake the responsibility to protect their cultural heritage and pass it on to the generations to come. However, in countries like Greece, where top-down approach is prevalent due to a strong state-oriented heritage policy, local communities are left with only minor parts of their heritage to look after.

After a decade's experience in working with local and rural communities, Time Heritage attempts to systematize participatory approaches through specific tools, enabling local communities to undertake the curation of their tangible and intangible heritage, as well as to gain a deeper understanding of their collective memory and cultural trends as heritage assets.

This paper discusses experiences and insights about local communities' responses to participatory approaches and associated technologies, based on evidence from two recent interventions: the Digital Curator for Small Museums [DigiSmALL], and the Digital Storyteller for Refugees' Attica [DigiStoryteller].

DigiSmALL is a database platform, doubling as a network of small museums, aiming at resolving long-standing problems of small museums, such as lack of digitization, digital presence, audience development know-how and access to funding. An offspring of Time Heritage and FAB LAB, the University of the Peloponnese laboratory for Knowledge and Uncertainty, it empowers small museums and local agents to take digital ownership of their collections and assets.

DigiStoryteller is the result of a collective project led by the University of West Attica, aiming at enhancing the heritage of Asia Minor refugees who settled in Attica in the 1920s, through digital storytelling. Combining historically curated material with a crowdsourcing platform, it invited local communities to undertake and share community-based documentation of their local history.

10 EMBRACING MULTIVOCAL HERITAGE: INTRODUCING THE MEMORY LAB AS THE CORE CONCEPT OF THE HERITAGELAB INITIATIVE

Yalman, Nurcan (Istanbul Nisantasi University) - Cappalletto, NiccoloAcram (Graduate Student in Arts, Museology and Curatorship University of Bologna)

This presentation introduces the newly launched HeritageLab, a pioneering interactive online memory museum aimed at challenging traditional notions of heritage and fostering a more inclusive, community-based, and transnational approach to collective memory. Historically, heritage has been monopolized by those in power, leading to exclusionary narratives and the marginalization of diverse voices. The HeritageLab initiative challenges this paradigm by giving voice to the multifaceted nature of heritage that exists beyond the confines of official designations, traditional boundaries, and also geographical frontiers. Drawing on the insights shared in "We Question Heritage's Past" and "We Embrace Heritage's Future," we advocate through practice a reevaluation of what constitutes authentic and traditional heritage, prioritizing the importance of individual valuations and community narratives. Thus, an intersecting set of Memory Labs is at HeritageLab's core. Each Memory Lab includes an interactive digital map in which individuals from diverse backgrounds can collectively contribute to the preservation, recognition, and sharing of their heritage, empowering local communities as key stakeholders in the interpretation of their heritage. The HeritageLab's Digital Universe allows for these labs to intersect to explore shared heritage narratives spanning time, space, and identity. Additionally, these maps recognize the significance of diverse storytellers-- artists, scientists, and scholars-- in enriching our understanding of heritage, transcending disciplinary boundaries, and embracing multiple forms of knowledge production.

This presentation could also be considered as an invitation to envision a more inclusive and multivocal approach to heritage and digital museums, one that celebrates diversity, fosters dialogue, and promotes justice and equality in commemoration efforts worldwide.

11 MANAGING THE UNDERGROUND BUILT HERITAGE: THE HELLENISTIC NECROPOLIS IN NAPLES

Pace, Giuseppe (CNR - Institute for Research on Innovation and Services for Development) - Fatigati, Luisa (CNR - Institute for Research on Innovation and Services for Development) - Esposito, Gabriella (CNR - Institute for Research on Innovation and Services for Development)

This presentation explores the fascinating case of the Naples' Hellenistic Necropolis, through the study of three underground sites in the Vergini neighbourhood, a part of the Neapolitan territory included in the Sanità district. These sites, opened to visitors, are owned and managed by privates and no-profit associations. Through several interviews, the Authors define different management models for each site and analyse their performance. Sites are not fully sustainable, and their fragmented management reduces the sites' potential to become one of the most visited and studied sites in the World. Based on the results of the COST Action Underground4value, the presentation proposes an integrated approach to the heritage management, able to connect local authorities, national museums, state antiquity protection bodies, foundations, associations, and privates. Dialogue and strategic thinking could make each site part of an integrated system, the Hellenistic Naples, and attract the needed resources for the site's overall sustainability. Creating such a win-win situation could expand the attractiveness of participatory practices and cultural transitions in the field of heritage management.

12 TEACHING AND LEARNING OF CULTURAL HERITAGE. BRIEF EPISODES FROM THE ACTIVITY OF COMMUNITY ARCHAEOLOGY ASSOCIATION IN HUNGARY

Füredi, Ágnes (Hungarian National Museum) - Rácz, Tibor Ákos (Community Archaeology Association; Ferenczy Museum Centre)

Over the past 10 years, people passionate for the past increasingly sought active contact with archaeologists and archaeological research in Hungary. However, the need for day-to-day engagement with the public and authentic transmission of recent scientific findings often exceeds the capacity of research centres and museums. The Community Archaeology Association, founded in 2019, acts as an intermediary between heritage institutions and the civilian community, thus meeting a well-defined cultural need of the society. Our association carries out archaeological field activities in cooperation with heritage institutions with the help of non-professional volunteers to learn about and preserve archaeological heritage.

We wish to present two case studies, each of them exploring different aspects of the integration of civilians into heritage preservation and rescue work. A programme series comprising ten field events to research archaeological sites under special protection in Pest County using modern site diagnostics methods was carried out in spring 2022. Our programme focused on surveying the condition of sites. The work was done in inter-institutional cooperation merging the Cultural Heritage Studies Programme by the Central European University, archaeologists from the Ferenczy Museum Centre of Pest County and a research project by the Community Archaeology Association. It studied how local communities can be involved in protecting cultural heritage by raising awareness and developing the cultural heritage site at Pomáz for cultural tourism purposes.

Volunteers made spectacular contributions to data collection on prestige finds from the 10th century, a period of settlement and taking roots of Hungarian population in the Pannonian Plain and participated in a series of research excavations of cemeteries from the era. Our second case study highlights how concrete research results can be obtained with civilian help.

13 SHARING HISTORY AND INTERPRETATION FOR UNDERGROUND BUILT HERITAGE: THE CASE-STUDY OF THE PISCINA MIRABILIS

Lombardi, Giovanni (CNR) - Surla, Tamara (University of Novi-Sad) - Pace, Giuseppe (CNR - Institute for Research on Innovation and Services for Development)

The presentation delves into the relationship between historical research and community engagement, mainly in the context of the Underground Built Heritage (UBH). The work, result of the COST Action CA18110, uses the case study of "Piscina Mirabilis" in Bacoli (NA) to explore this dynamic. Historical research is not confined within its disciplinary boundaries. It must engage with theoretical and practical issues, often dealing with unforeseen matters and social involvements that shape the heritage characterisation. This necessitates an openness to local communities while maintaining objectivity. The presentation highlights the potential friction between history and community memory in interpreting UBH. It explores the demands historians often face, which involve confronting different perspectives and languages. This opens up interpretative issues on history/memory connections, handling the polysemy of sources, re-signification of places, and cultural transitions. The presentation underscores the importance of fostering an open dialogue among scholars, stakeholders, institutions, and local community. This dialogue, based on strategic transitions, serves as a means of local empowerment. It helps participants share old and new meanings, bringing places out of the shadow cone of no-value or misconception. The case study provides an opportunity to analyse how historians deal with participation and the ever-evolving signification of places. By merging history, traditions, meanings, and memories, the presentation offers a set of problems induced by tourism in terms of community identity and self-recognition. Finally, through semi-structured interviews with Piscina Mirabilis's stakeholders, it outlines potential development pathways, governance mechanisms, and current challenges for the site's development, reuse, and valorisation. Interaction with different local stakeholders, both public and private, aids in understanding their viewpoints. This is a crucial step towards a shared interpretation linking history with traditions and supporting multi-stakeholder engagement in the valorisation process. This approach underscores the importance of collaboration and inclusiveness to heritage preservation and valorisation.

14 OVERVIEW OF THE CULTURAL ROUTES OF THE COUNCIL OF EUROPE PROGRAMME IN HUNGARY. NATIONAL AND INTERNATIONAL NETWORKS, EXAMPLES OF GOOD PRACTICES

Tompos, Krisztina (Hungarian Open Air Museum (Szabadtéri Néprajzi Múzeum))

What kind of role can thematic routes across countries play in safeguarding heritage and making it accessible? Which opportunities are offered by the Cultural Routes Programme and its related scientific and civil networks? How can the benefits of the Programme be realised at national or even at local level?

In my presentation I would like to focus on the questions mentioned above and present the activities of the Cultural Routes Programme in Hungary and its widely applicable experiences, which can be used in raising awareness of archaeological heritage in the community.

The Directorate of Intangible Cultural Heritage of the Hungarian Open Air Museum has coordinated the Cultural Routes Programme in Hungary since 2019 on the mandate of the Minister responsible for the culture. The Hungarian Open Air Museum, established in 1965, has a significant professional knowledge basis in the safeguarding of cultural heritage, raising its visibility, involving visitors and making the heritage more accessible to the community. Since 2009, the Museum has also placed increasing attention on intangible cultural heritage through the Directorate of Intangible Cultural Heritage, which has been responsible for the professional coordination of the Cultural Routes Programme in Hungary since 2019 as well.

Hungary has already connected to 12 cultural routes, such as the Iron Age Danube Route, European Route of Historic Thermal Towns, Saint Martin of Tours Route, Roman Emperors and Danube Wine Route, etc. The associations which organise these routes connect academic and civil networks, international and local communities. As the Hungarian coordinator of the Cultural Routes Programme, the Hungarian Open Air Museum supports the cooperation of the routes within the country and encourages the exchange of professional experiences, the sharing of ideas and common planning.

15 MID-TERM STRATEGY FOR THE IRON AGE DANUBE ROUTE

Czifra, Szabolcs (Hungarian National Museum)

Four years ago, experts in archaeology, cultural heritage protection, and tourism, as well as local stakeholders, founded an international association aiming to raise public awareness of fragile Iron Age landscapes and offer sustainable strategies for their research, protection and management. The unique heritage tourism initiative Iron Age Danube Route achieved its primary goal in May 2021, when it became certified Cultural Route of the Council of Europe. This opened many new and exciting opportunities for its members and partners (including museums) to empower their cooperation and community engagement. This presentation will examine the cultural route in light of the interrelationship between archaeology, museums and tourism, using widely accepted planning tools to research the current state and design further steps in cooperation. A STEEPLE analysis helps to understand the route's macro-environment through political, technological, economic, environmental, political, legal and educational factors. Adopting Porter's model to the route, I identify and examine five competitive forces that shape the network and must be considered in order to better position our initiative in the marketplace. Finally, I assess internal and external factors and the current and future potentials of the route in a SWOT analysis, which helps to hammer a mid-term development plan in three key areas, especially highlighting museums' role in future actions.

16 MOVING TOWARDS THE ARCHAEOLOGICAL NATURAL PARC OF THE SINIS PENINSULA. THE ACTIVITIES OF THE FONDAZIONE MONT'E PRAMA

Mureddu, Maria (Fondazione Mont'e Prama) - Camedda, Nicoletta (Fondazione Mont'e Prama) - Orri, Ilaria (Fondazione Mont'e Prama) - Becciu, Marica (Fondazione Mont'e Prama) - Fadda, Sara (Fondazione Mont'e Prama) - Pitzalis, Matteo (Fondazione Mont'e Prama) - Murru, Giorgio Franco (Fondazione Mont'e Prama) - Muroni, Anthony (Fondazione Mont'e Prama)

The cultural heritage of the territory of Cabras, in the Sinis Peninsula, Central-West Sardinia (Italy), has recently passed under the charge of the Fondazione Mont'e Prama, instituted by the Ministry of Culture of Italy, the Sardinian Region and the Municipality of Cabras. At the moment the Foundation manages the Iron Age site of Mont'e Prama, a necropolis of the Nuragic civilization monumentalised around the 9th-8th c. BC with a unique statuary complex; the archaeological site of Tharros, with its Bronze Age Nuragic village and the Punic, Roman and Late Antiquity city; the palaeo-Christian church of San Giovanni; the hypogeum of San Salvatore, a sanctuary frequented from the IV c. AD; the Archaeological Museum of Cabras, which exhibits the findings from the cited sites and from other excavations and surveys held in the Peninsula and in underwater excavations near the Sinis coast. The Foundation operates to enhance and promote the fruition of the territory with an integrated approach, involving the archaeological sites altogether with all productive sectors correlated to the cultural aspects. The cultural-touristic development of the area of Cabras is taken into great account, and inserted in a broader regional and over-regional network. One of the other aims is the development of the research, either with activities conducted by the same Foundation or sustaining and collaborating with Universities and other institutes. Specific actions, as conferences for all types of public, didactic projects with schools, innovative partnerships with regional and international actors, together with renovations of the expositions and of the ways of communicating, are undertaken. The final objective is to contribute to the development of the community, to enhance its commitment thanks to the participatory approach, and its awareness of the value of the cultural heritage in general terms as well as in concrete situations of life and human interactions.

17 RESEARCH OF ROMAN VILLAS IN COUNTY VESZPRÉM - A COMMUNITY ARCHAEOLOGY PROJECT

Péterváry-Szanyi, Brigitta (Laczkó Dezso Múzeum)

Community archaeology in county Veszprém has its origins around 2015 when the first metal detectorists joined in the researches of the museum. Since then a scientific research plan was formed to provide a backbone for the investigation, focusing on the Roman road network and settlement pattern. During the years an experienced and very enthusiastic team has formed. The program provided training in theoretical and on-site knowledge, also in preparing the finds for further examination. The latest project focuses on the villa buildings of the Balaton uplands. It is a complex programme, running for two years. This is the first research of the museum, where the volunteers are participating not only in the fieldwork, but in every aspect of the project, from the desk-based research up to the publication and building an exhibition presenting the results. This presentation draws up the project plan, emphasising the detailed roles of the volunteers. Also presents the first phase of the research, completed until the summer of 2024. Finally a short analysis of the first experiences is included.

18 THE CRESWELL VOLUNTEER ARCHAEOLOGY PROJECT: INSIGHTS INTO INCLUDING RURAL COMMUNITY RESIDENTS IN ARCHAEOLOGY AND HERITAGE

Nelson, Theresa (Department of Archaeology, University of Sheffield; Creswell Heritage Trust, Creswell Craggs, UK) - Kuykendall, Kevin (Department of Archaeology, University of Sheffield, UK) - Jones, Angharad (Creswell Heritage Trust, Creswell Craggs, UK)

Creswell Heritage Trust (CHT), or Creswell Craggs, is an enclosed limestone gorge on the Derbyshire/Nottinghamshire border of England and includes caves occupied during the last Ice Age. Located in Creswell, England, which is within the top 10% to 20% of the most deprived areas in the country, this rural heritage site is striving to support local communities impacted by the aftermath of mining and deindustrialisation whilst repositioning itself as an 'archaeological park' inviting visitors to "walk in the footsteps of early humans and woolly mammoths. In 2023, the Creswell Volunteer Archaeology Project (CVAP), a collaboration between the University of Sheffield Department of Archaeology and CHT, successfully enacted a model of community-engaged archaeological fieldwork to understand how to mobilise public perceptions and better understand the role of archaeology for audience development and programming. CVAP successfully recruited a cohort of local community residents to participate in an excavation, implemented pre- and post-excavation interviews for participants to understand their views before and after excavation participation, and disseminated a public survey for community members to better understand and include views on archaeology and Creswell Craggs. At the end of the project, CVAP and its participants co-produced a free museum exhibit at CHT and a local cafe, "The Community Experience: Archaeology at the Craggs," which included a documentary created by and from the perspective of a local Creswell resident and Seasonal Service Assistant at CHT. Our 2023 work provides insights on good practices in heritage management for other rural, cultural tourism sites, including: interacting with socioeconomically deprived communities via social media engagement, physical flyers, and free, in-person events outside of heritage sites; methods of communication with local community members and heritage staff to include their voices and perspectives; and co-producing informative museum exhibits which are accessible both within and outside of rural heritage sites.

19 COMMUNITY ARCHAEOLOGY IN THE GÖCSEJ MUSEUM. ARCHAEOLOGICAL RESEARCH OF PAULINE MONASTERIES IN ZALA COUNTY, HUNGARY

Havasi, Balint (Directorate of Museums in Zalaegerszeg - Göcsej Museum) - Simmer, Livia (Directorate of Museums in Zalaegerszeg - Göcsej Museum)

Our presentation displays the programme "Community Excavation of the Pauline monasteries". The project, launched on a civil initiative in 2016, kept evolving and has reached the level of cooperation on the scale of social participation by today. Since the beginning, we have aimed at approaching and involving the widest possible range of stakeholders. The focus – the past of a particular settlement and the history of the Pauline order – attracted both people interested in archaeology, Christian volunteers, and archaeology students looking for a field practice opportunity. Besides, we also attempted to reach local governments and mayors, local tourism agents, local NGOs, higher education institutions, the Hungarian Pauline Order, and local businesspersons and companies.

The project received a grant from the National Cultural Fund in 2022. The support has enabled us to continue the recent community excavations and the non-destructive geophysical investigations. The grant also helped us to summarise the results of the archaeological and geoinformational research of the last years.

1163 COPING WITH CONFLICTS. INVESTIGATING DEESCALATION STRATEGIES IN PRE- AND EARLY-STATE COMMUNITIES

Session theme: 4. Persisting with Change: Theory and Archaeological Scrutiny

Session organisers: Loy, Anna (Christian-Albrechts-Universität zu Kiel (CAU); ROOTS Cluster of Excellence) - Gentile, Valerio (Leiden University) - Andersen, Anna-Theres (Christian-Albrechts-Universität zu Kiel (CAU); ROOTS Cluster of Excellence)

Session format: Regular session

The importance of de-escalation and peaceful resolution of conflicts is of tragic relevance nowadays. In Conflict Archaeology the material traces of primarily violent events have been the focus within the last decades. Consequently, despite their historical and political significance, the material evidence for de-escalation strategies has received limited attention in archaeological research and remains underrepresented.

De-escalation and resolution strategies can be considered an integral part of conflict dynamics, profoundly influencing the social consequences and economic costs for the communities involved.

Nevertheless, differing from the historical sciences, where the assessment of non-violent conflict resolutions relies on the availability of written records, archaeologists often contend that demonstrating de-escalation processes is challenging.

This session aims to stimulate a comprehensive discussion on the potential archaeological evidence that could shed light on de-escalation strategies. For example, recent archaeological studies have discussed fortification sites or weapon hoard finds as potential indicators for conflict resolution in past societies. Furthermore, it provides a well-rounded perspective on the multifaceted nature of conflict archaeology and the enduring relevance of de-escalating approaches in the quest for cooperation within human societies.

We invite contributions from diverse time spans (pre- and early-state communities), disciplines, and geographical perspectives.

ABSTRACTS

1 SYMBOLIC EXPRESSION AND HANDLING OF WEAPONS AS A DE-ESCALATING STRATEGY

Borake, Trine (Museum Vestsjælland, Denmark)

The discovery and investigation of weapon graves, magnate residences and defence systems, along with historical accounts of Viking plundering have fostered a general idea of a militarised society and martial social organisation in Scandinavia Iron Age (550 A.D. -1050 A.D.) However, studies of weapons from an accumulated body of detector material from Denmark demonstrate a complex composition. It is characterised by a majority of parade weapons, a dispersed distribution including rural and ritual sites and depositions, typology transformation and transgression, and deviating warrior symbolism. Furthermore, we see a symbolic destruction of weapons and few defence weapons. The reasons and arguments for this development are multiple. Here, I will propose that transforming the notion of weaponry as a means of aggression, violence, or threat of violence into a symbolic and ritualised expression served as a de-centralising and de-escalating strategy. This paper will present the development in weapon distribution and symbolism in the first millennium with a special focus on metal detector material from Denmark and discuss the expression and handling of weapons in the late Iron Age as a potential indicator for conflict resolution. The theoretical argument is based on an anarchistic perspective, where decentralisation in various forms is central.

2 DIS-ARMING THE PAST: DEPOSITING DELIBERATELY DESTROYED WEAPONS ON EARLY IRON AGE ÖLAND, SWEDEN, AS A CONFLICT RESOLUTION STRATEGY?

Nordin, André (Stockholm University)

In Conflict Archaeology, weapons constitute one of the key material indicators of prehistoric warfare. The presence and availability of weapons, as indicated by their material remains, are commonly seen as facilitating conflict in pre-history. While weapons have been central to understanding past conflicts, little attention has so far been given to the actual weapons themselves and the roles they might have played in de-escalating conflict. For example, in Early Iron Age Sweden, some weapons have been deposited in a damaged state in burials, wetlands, and on settlements. This is a phenomenon that has been observed since the 19th century. Previous research has recognised that some of this damage may have been directly inflicted on the weapons themselves, prior to deposition. By being damaged and deposited, weapons are effectively removed from circulation in society, possibly contributing to the disarming of society, whether directly or indirectly. In this paper, I will explore how the practice of deliberately damaging weapons and their subsequent depositions relate to conflict resolution strategies in the past. As a case study, I will examine the

weapons from two Early Iron Age sites from central Öland, Sweden: the cemetery of Sörby-Störlinge and the nearby wetland depositional site of Skedemosse. Both sites are more or less contemporary, and both sites feature deposited weapons that have been deliberately damaged. In order to further expand the archaeological analysis of deposited deliberately damaged weapons, I will also make use of anthropological theory relating to de-escalation and conflict resolution strategies.

3 DUELS & DEPOSITIONS. EXPLORING BRONZE AGE DE-ESCALATION STRATEGIES THROUGH EXPERIMENTATION AND MICRO-WEAR ANALYSIS

Gentile, Valerio (Leiden University; University of Göttingen)

It is common opinion among scholars that European Bronze Age had strong martial connotations. During this period, weapon technology underwent fast development and weaponry spread in large numbers across the continent. Weapons also played a role in the ceremonial sphere: thousands of swords and spears were intentionally removed from circulation and buried together in hoards or thrown into rivers. In many cases, these items were also deliberately bent and broken. On the other hand, conflict in the Bronze Age was also a harsh reality: in recent years, archaeological and osteological research has increasingly uncovered material evidence of violent conflicts among large groups of individuals.

How and to what extent was armed conflict sustainable for Bronze Age communities? What strategies could have been implemented by non-state groups in order to manage conflict and prevent it from constantly escalating?

This paper discusses the application of a combined approach - consisting of experimental investigation and analysis of use-wear traces - to the study of ceremonially deposited Late Bronze Age weaponry in the Low Countries. The ways and frequency in which these items were used provide precious information on how armed conflicts were conducted and on how casualties could have been mitigated. Furthermore, the steps that preceded how some of these weapons were discarded seem in-tune with de-escalation scenarios.

4 PLACES OF CONFLICT - PLACES OF COPING?

Loy, Anna (ROOTS Kiel)

Fortifications come in various kinds and forms - and locations. They constitute a longstanding element within the conflict-related practices of various communities. But what can they tell us about conflict management strategies?

Understood as tangible expressions of perceived conflict potentials each fortification follows its unique trajectory, yet certain common parameters can be discerned - Specific places within any given landscape afford different levels of defensibility. This paper delves into the discussion and presentation of measures of defensibility associated with different fortifications dating back to the first Millennium BC in the region surrounding the south-western Baltic Sea. Hence, how can an approach based in landscape archaeology enhance our understanding of these structures?

Additionally, the previously explained generalised method of defensibility inquiry is evaluated, examining its utility and potential scope for further archaeological research. By exploring the defensibility of fortifications, this research aims to contribute valuable insights into the broader understanding of conflict management strategies in past communities.

5 THE SINTASHTA PARADOX: A NON-WARRING WARRIOR CULTURE FROM THE BRONZE AGE?

Semyan, Ivan (Institute of Archaeology and Ethnography NAS RA)

The Sintashta archaeological emerged for a relatively short period during the end of 21st and 19th centuries BC in the foothills of Southern Urals and the adjacent Kazakhstan steppes. Today we know its 25 large settlements with impressive fortifications, yet none bears the signs of siege or attacks. The contemporaneous burial mounds yielded troves of bronze weapons, elaborate jewelry, massive remnants of animal sacrifices, luxuries delivered by long-distance trade (e.g. Badakhshani lapis-lazuli, cotton cloth from Indus Valley). But the greatest surprise so far were the chariot complex including harness details - cheekpieces, earliest known examples of spoked wheels and chariot horses. The Sintashta culture must have achieved significant breakthroughs in the techniques of metallurgy, monumental construction, and the use of animals. The evidence likely suggests a concentration of wealth in the hands of warrior elites. The puzzle is that we find no traces of organized violence in a culture marked by its innovations in chariots, fortifications, battle axes, spears and compound bows. By contrast, the signs of military disasters abounded in the "simpler" Bronze-age communities both before and after Sintashta epoch in the same landscapes. It appears that the Sintashta elites found an effective de-escalation strategy by monopolizing access to highly specialized, expensive weapons and creating impregnable fortifications in the times when siege tactics were not yet effective. But the trade-offs of vertical controls apparently proved unsustainable. Tentatively, I submit for discussion the hypothesis that the extraordinary concentrations of humans, metal-casting, as well as cattle and horses in the same fortified compounds resulted in the depletion of natural environments from overgrazing and pollution. The twin paradox of stationary pastoralism and a well-armed peace under elite control tended to last no longer perhaps a century and half.

POST-VIKING ERA POPULATION OF SAMBIA AND ITS CONTACTS IN THE MIRROR OF MODERN SETTLEMENT ARCHAEOLOGY

Prassolow, Jaroslaw Aleksei (Leibniz Zentrum für Archäologie (LEIZA-ZBSA)) - Skvortsov, Konstantin (independent researcher)

The archaeological legacy of the Post-Viking era Sambian Peninsula (modern Kaliningrad region of Russia and the former administrative district of Fischhausen/Samland in the German province of East Prussia) provides evidence of numerous and multifaceted relations between its medieval population and both close and remote contacts. Indications of trade, cultural exchange, migrations, cooperation and military confrontations with other tribes and peoples are richly present in the local burial monuments up to the end of the 13th century (colonization by the German Teutonic Order). Unfortunately, another essential category of data sources on the everyday life of the medieval Old Prussians – unfortified settlements, remains poorly investigated so far. This in turn limits the possibilities of modern archaeological research, in both the study of various aspects of the everyday life of Sambia's population and the reconstruction of the local medieval settlement structure. Some general knowledge of a few unfortified settlements, which were discovered before 1945, can be reconstructed by means of the comparative analysis of the partially preserved pre-war German archival records. Unfortunately, these archives as a rule neither shed light on the internal structure of the settlements in question nor provide detailed information on the material culture and chronological stratification of these archaeological sites. However, the situation has slowly started to change due to the field research campaigns of recent decades. These new and often unexpected investigation results allow a deeper insight into the current concept of the interregional communications of the Old Prussians in the 11th-13th centuries AD as well as the reviewing of it. We have firm material evidence that the settlements in question both profited from their integration into the wide-stretched, mutually enriching, communication network and suffered in the devastating local military conflicts.

1165 COLLECTING ACROSS BORDERS: HISTORIES OF COLLECTING AND CURRENT DEBATES ON COLLECTIONS

Session theme: 3. The Life of Archaeological Heritage in Society

Session organisers: Ojala, Carl-Gösta (Uppsala University) - Kato, Hirofumi (Hokkaido University)

Session format: Regular session

This session critically investigates interrelations between ideologies and practices of collecting, and concepts and constructions of borders. Today, there is a great need to address histories of colonial and imperial collecting, and the impact of collecting on the construction and understanding of borders and identities, in the past as well as the present. In many places in the world, local and Indigenous groups are today claiming the right to self-determination in heritage issues and demanding repatriation of museum collections. There is a need to deal with sensitive and traumatic histories, and to discuss how to handle contested collections in the future.

We invite papers dealing with, for instance, histories of collecting, concerning both material culture and human remains, histories of assembling collections, interrelations of ideologies and practices of collecting with various understandings of borders and identities, as well as protest and resistance from local and Indigenous communities against the collecting, excavation and plundering of material objects and ancestral remains. We welcome critical reflections on the politics and ethics of collecting over time, and encourage contributions that highlight critical current issues from different angles, from academic, heritage management and community perspectives.

We especially encourage contributions dealing with minority and Indigenous heritage. Papers might discuss specific case studies or more general and comparative themes. We also welcome papers dealing with networks of scholars and collectors, stretching across borders.

In the session, we would also like to address contemporary consequences of the histories of collecting and the importance of the collected heritage today. We invite contributions addressing present-day debates, collaborations and conflicts connected with histories of collecting across borders, and with current shifting borders and changing power dynamics, including decolonization, repatriation and reburial processes. We aim for an open and inclusive discussion in the session, with focus on possible constructive paths forward.

ABSTRACTS

1 COLLECTING ACROSS BORDERS IN SÁPMI: HISTORIES AND LEGACIES OF COLONIAL COLLECTING

Ojala, Carl-Gösta (Uppsala University)

In recent years, topics concerning histories and legacies of Nordic colonialism in Sápmi (the core areas of the Indigenous Sámi population) have been increasingly discussed by scholars. As part of this much needed broader examination of Nordic colonialism in Sápmi, there is also a need to recognize and critically examine legacies of colonial collecting. This paper discusses aspects of collecting across borders in Sápmi, and the importance of transnational networks of collectors – a theme that has been little examined in earlier research.

Histories of colonial collecting include, for example, the early modern collecting of Sámi material culture, such as the sacred Sámi drums that were confiscated and collected in the 17th and 18th centuries, and the collecting of Sámi human remains in the 19th and early 20th centuries, as part of racial science and the assembling of craniological collections in the Nordic countries and elsewhere. In recent years, Sámi individuals, groups and institutions have raised demands for greater self-determination in heritage issues and respect for Sámi cultural rights, which have included demands for repatriation and reburial.

This paper discusses some of the challenges for scholars and research and heritage institutions in this field of tension between past and present. The paper addresses the current situation concerning repatriation and reburial processes, and their wider implications and significance, in the Nordic countries, stressing the importance of examining the politics, ethics and power dynamics of archaeology and heritage management, as well as the importance of border politics, when discussing histories and legacies of colonial collecting.

2 CULTURAL HIERARCHIES, HIGHLIGHTING INDIGENOUS COLLECTIONS IN THE VATICAN MUSEUMS

Aigner, Katherine (The Australian National University)

The great Vatican Exhibition of 1925 was curated by the eminent missionary, ethnologist, and linguist Father Wilhelm Schmidt SVD (1868–1954). With networks of missionaries such as Paul Schebesta (in Africa and southeast Asia), Martin Gusinde for the Fuegini (South America), Franz Kirschbaum and also Georg Höltker in Papua New Guinea and Ernest Worms in Australia, Schmidt developed theories that challenged the separation of humankind, or the 'progression' from nature to culture, popular at the time, instead valuing indigenous knowledges and cultures. His work on archaeological and cultural collections, highlighted in the 1925 Exhibition, ushered in a new era of study of so-called 'hunters and gatherers'; he stressed their similarity and intelligence. But did Schmidt's work create another artificial separation of cultures? Through specific case studies, this talk looks at the interrelations between Schmidt's theories, the construction and understanding of identities in the Anima Mundi, Peoples, Arts and Cultures collection (Vatican Museums), and how collaborations with the indigenous communities have enhanced our understanding of tangible and intangible cultures.

3 SCATTERING EGYPTIAN COLLECTIONS: THE CASE STUDY OF PREDYNASTIC AND DYNASTIC LITHIC ARTEFACTS

Lombardi, Lorena (University of Pisa; National Research Council-Institute of Heritage Science (CNR-ISPC))

Many of the most important Egyptian collections in Italy and worldwide were acquired or donated between the end of the 19th and the beginning of the 20th century. Their full accessibility and understanding is limited by several factors, such as the paucity or lack of contextual information due to the nature of their acquisition as antiquarian markets or old archaeological practices, especially along the Nile Valley, and because many of them were originally part of unified collections, but are now scattered in different museums. At the same time, it is through these collections and their study that the magnificence of Pharaonic Egypt continues to impress the public. However, there is one important group of artefacts that is still little studied: the Predynastic and Dynastic lithic industries.

This presentation aims to highlight the potential of the study of ancient museum collections originally related to each other, and to reconnect the scattered artefacts of some important contexts, such as Wadi el-Sheikh, the Thebes area or Abydos cemetery, which are kept in different museums. Although much data on the original contexts has been lost due to urbanisation or lack of research in some areas, the combination of a techno-typological analysis of the lithic artefacts, the study of the available archival documentation and the comparison of the collection with other recently excavated contexts allows us to shed new light on these often dismissed collections. By cross-referencing data from different museums, it is possible not only to reconstruct the history of the collections and the people associated with them, but above all to recontextualise the artefacts and place them in their original context in Egypt.

4 PRE-COLUMBIAN MUMMIES IN EUROPEAN MUSEUMS - INTERDISCIPLINARY AND TRANSNATIONAL EXPERIENCES AND OBSERVATIONS FROM AN ONGOING RESEARCH PROJECT

Gerst, Robin (Goethe-Universität Frankfurt am Main)

This lecture presents the experiences I was able to gather in the course of my ongoing research project on pre-Columbian mummies. It is a kind of experience report on how different the handling and research can be. Thus, I see my results as personal experiences, but also as a basis for exchange for a selected group of this culturally sensitive material in archaeology, which, however, offers many opportunities for comparison.

South American human remains are represented in many museums and research institutions in Europe, in far more than one might expect at first glance.

These results were collected in more than 50 museums and research institutions in nine countries (more to follow). There is little comparative research on this, and there is no database or comprehensive catalogs. However, there are major differences within Europe in terms of distribution, research and museum presentation.

Human remains have special requirements: I will use examples to show how these mummies are cared for and exhibited in museums by the various scientific disciplines and, in particular, how these approaches differ.

This also concerns the ethical backgrounds that arise from this. There have recently been major changes in terms of sensitivity. Pre-Columbian remains, which originate from archaeological contexts but are often assigned to the ethnology departments of museums, have been particularly affected. This manifests itself in the current challenges in museum handling (focus on pre-Columbian mummies): Changes in exhibition/didactics, museum objects with a “colonial context”, dealing with concerns of communities of origin, provenance research, repatriation issues etc.) but also the day-to-day difficulties of conservation and research.

I would like to compare experiences and lessons learned on these points and discuss suggestions and examples of best practice.

5 THE NUBIAN SKELETAL COLLECTIONS CURATED AT UNIVERSIDAD COMPLUTENSE DE MADRID

Casquero Muñoz, Mar (Universidad Complutense de Madrid) - Ríos Frutos, Luis (Universidad Complutense de Madrid) - Saad, Mohamed (National Corporation for Antiquities and Museums (Sudan))

Archaeological work in present-day Sudan began during the British colonial administration, with large scale projects like the Archaeological Survey of Nubia, carried out by foreign archaeological missions that usually viewed Nubia as a cultural extension of Egypt. It wasn't until 1960 that Sudanese involvement in both archaeological work and legislation commenced, with the first Sudanese appointed Commissioner for Archaeology. Since then, various foreign teams have conducted joint archaeological excavations with the Service of Antiquities of Sudan (now National Corporation for Antiquities and Museums). Between 1978 and 1981, a Spanish archaeological team excavated the cemetery of Amir Abdallah (AAM), in northern Sudan. This collaboration allowed the discovery and characterization of a new archaeological culture known as Early Meroitic (III-I B.C.). The license granted by the NCAM permitted the export of the remains of around 380 individuals to the Universidad Complutense de Madrid (UCM) for its study.

In this work we discuss the Spanish archaeological missions to Sudan and Egypt, focusing on the importance and treatment of human remains, from the excavations of Meroitic and X-Group cemeteries in Argin under the UNESCO International Campaign, to the AAM cemetery. Half a century after its excavation, the collections curated at UCM present an unexplored resource. We discuss current avenues of research that could contribute to the better understanding of the social and cultural dynamics of ancient Nubia, and frame this discussion within broader issues of decolonization, better and more accurate representation of Nubian history, and involvement of Sudanese colleagues, a matter complicated by the current conflict.

6 CROSS BORDER EXCHANGE OF THE INDIGENOUS REMAINS

Kato, Hirofumi (Hokkaido University)

The Indigenous repatriation movement began in Japan in the 1980s, however, systematic repatriation was not implemented until the 2000s. At the request of the Ainu Association of Hokkaido and others, the Japanese Government surveyed ancestral remains of the Ainu stored in universities and museums in Japan. As a result, it was found that over 1,700 remains were stored at 12 universities and 18 public museums in Japan. Repatriation of the ancestral remains from the universities and museums to the local communities is progressing, however, there are remains whose repatriation destination has not been decided, and they are currently being kept at the National Resting Place.

On the other hand, it is obvious that the ancestral remains of the Ainu are stored in museums and research institutions abroad. The whole picture is unidentified and the collection history is unknown. However, during the process

of research into the repatriation from Australia in 2023, it became obvious that an exchange of ancestral remains of Indigenous peoples was taking place between scholars.

The purpose of this paper is to point out that an international network of collection exchanges existed in the background of the collection of Indigenous human remains. I would also like to mention that this international network was related to the flow of international researchers fostered in Europe in the 19th and early 20th centuries. I would also like to point out the importance of international collaboration in solving this issue.

1166 HISTORY WITHOUT CROSSROADS? CENTRING THE PERIPHERY OF THE MEDITERRANEAN

Session theme: 5. All Roads Lead to Rome: Multiscalar Interactions

Session organisers: Gheorghide, Paula (University of Helsinki) - Johal, Prabhjeet (University of Toronto)

Session format: Regular session

Crossroads are often considered emblematic representations of liminal spaces, places of passage rather than origin, often distinguished by their transient nature and multi-ethnic populations. Both Western and Classical epistemologies have produced a dichotomy between “crossroads” and “centres” for theoretical and heuristic purposes in describing many sites in the East. The adage “all roads lead to Rome” has served as a metaphor for the intrinsic link between “central hubs” and their periphery. This adage also highlights, however, how in western thought, that neither the centre nor its periphery could exist without the “crossroads” that connected multiscalar networks of interaction and so, demand reconsideration.

Still, scholarship has largely characterised places such as Palmyra or Hatra, as “in between” Rome and the Arsakid empire. Similarly, rooted in 18th to 20th century ideas of cultural and racial purity, crossroads in the Hellenistic world are often envisioned as “in between places” defined by their “hybrid” or “syncretic” material and linguistic culture. These “in between” places have also historically been utilized to define and distinguish what “Hellenistic” is from what it is not. Through frameworks such as the “Silk Roads,” the same could be said of Central Asian communities, largely defined by their position between China, India, and Persia and so, operate in Classical scholarship as a crucial hinge between the so-called “East” and the Eastern Mediterranean.

In this session, we welcome papers that explore the material culture of the Hellenistic to Roman periods from perspectives that challenge the historical framework of “crossroads. We hope to foster discussion with the aim of reimagining and re-centering “in between” places as fixed points of intersecting realities. Our goal is to undo the characterisation of “crossroads” as strictly points of transition in relation to and defined by “centres..

ABSTRACTS

1 CENTRING THE LOCAL IN GANDHĀRAN ART: THE MATERIAL EVIDENCE FROM SWAT

Elahi, Moizza (University of Toronto)

When it comes to ancient Gandharan art—the visual and material culture from the northwestern regions of the Indian Subcontinent—traditional scholarly practice provides a partial picture and does not, in many cases, adequately nuance the local, global, sociological, and material dimensions of the artistic and archaeological phenomena. Most approaches to this artistic tradition tend to cast it as a passive peripheral recipient of the active Hellenistic or Roman core cultures. To better understand and more effectively address the complexity of Gandharan art, it is imperative to highlight the local dynamics and agency embedded in the processes of production and use of Gandharan artefacts in tandem with the cross-cultural currents that characterize them. To this end, the present paper draws attention to the sculpture—statues, reliefs, and architectural elements—recovered from some of the early Buddhist monastic centers in the region of Swat in Greater Gandhara. By focusing on the materiality of these objects—the specificity of their material properties and the complexity of their entanglement with other objects and people—this paper aims to recover the significance and centrality of local action and agency in the making and unmaking of Gandharan cultural practice. In doing so it hopes to provoke discussion and dialogue beyond the usual Eurocentric originary debates and reductive discourses centred on artistic influences.

2 GLOBALISATION THEORY AS AN ALTERNATIVE TO ‘CROSSROADS’-THINKING: THE CASE OF DOLPHIN-AMPHORA EARRINGS FROM PASTORALIST BURIALS IN NORTHERN BACTRIA

Veltman, Merlijn (Leiden University)

Centre-periphery-crossroads thinking (CPCT) has undeniable effects upon how archaeologists and ancient historians investigate and categorise objects from ancient contexts in Central Asia. This approach leads inevitably towards attributing cultures to objects. By focusing on what objects are, objects become abstract and culturally representa-

tive. A vase with iconography stemming from the Hellenistic world becomes Greek, and a belt plaque with an animal combat scene becomes Saka or Xiongnu. By focusing on cultural connotations, the impact of the object, including its physical characteristics, is of little consequence. In CPCT, cultures are seen as homogeneous and static. Centres appear to contain the most homogeneous culture, peripheries less so, and crossroads a mix of various cultures. Does CPCT fit with evidence from the ancient world? Rome is arguably the 'centre' of the Roman Empire, yet is culturally profoundly heterogeneous, and not at all purely 'Roman'. It seems, a different approach is needed.

This paper proposes an alternative to thinking in centres, peripheries and crossroads, in the form of globalisation theory. This approach posits that connectivity and interaction are endemic to the ancient world, that objects are more-than-representative, and that cultures are flexible, shifting and locally conceived. In short, it focuses not on what objects are, but on what objects do. First, an examination of globalisation theory is given, and contrasted with previous approaches to cultural interaction. Second, a case study is presented to illustrate globalisation theory, focusing on the so-called 'Dolphin-amphora earrings' from several pastoralist burial sites in Northern Bactria (modern day Tajikistan). These earrings were conceived as evidence of Greek influence upon the identity of pastoralists in previous research. Globalisation theory, however, shifts the focus to what these earrings do in their context, illustrating the impact of these objects within the burial.

3 THE RELIGIOUS ECOSYSTEMS OF AI KHANOUM AND TAXILA AND THEIR RELATION TO HYBRIDISED ICONOGRAPHY

Nikolaou, Christos (University of Cambridge)

In this essay, I undertake a comparative analysis of the distribution of religious iconography in Hellenistic Bactria and Gandhara, using Ai Khanoum and Taxila respectively as proxies. I am using the reports of DaFA and John Marshall, as well as other relevant literature to construct accurate maps and databases of said iconography and comparing them to see different strategies of hybridity (Hoo, 2018). To do this, I am using GIS-based analysis (Laricella et al, 2017, Martinez-Seve, 2014), as well R, to identify the spread of religious structures and artefacts in the city. The article seeks to delineate a method for identifying how religious diversity manifests in Hellenistic urban landscapes. Specifically, the Hellenistic period in the region saw connectivity between the Greek, Indian and Iranian cultural spheres, and I hypothesize that these relationships were manifested differently under different regimes and in different regions (Hoo, 2018, 1-3). Through building a database which has all relevant material culture (so religious artefacts or artefacts with mythological iconography) as well as entries of all the buildings (or in the case of Sirkap mound, blocks as described by Marshall), which are all georeferenced for mapping purposes. I have organized columns which record information such as material of items, iconography, periodization etc. Using these columns, I produce Graphs in R and using the georeferenced coordinates, I make heatmaps of the distribution of specific categories of images and compare them in between the two cities. For instance, comparing the presence of terracotta figurines in domestic or ritual contexts, or where for instance Dionysiac imagery is present if at all in either site. In essence, I'm working on understanding how the religious ecosystems of either site were set up and how urban space allowed said ecosystems to manifest.

4 CULTURAL INTEGRATION ON THE "CROSSROAD": ICONOGRAPHY OF A CHINESE SILK JIN IN ROMAN PALMYRA

Zhou, Junjie (Ludwig-Maximilians-Universität München)

The caravan city of Palmyra in the first two centuries CE was not merely a peripheral frontier between Rome and the Arsacid Empire, but a hub of cultural contact and integration. Palmyra preserved nearly a hundred textiles of Chinese silk, one of the largest corpora ever survived from Antiquity. This paper will present a case study of one warp-faced compound tabby (jin in Chinese) to illustrate how cultural encounters in Palmyra actively generated a unique "hybrid" pattern. First, I shall introduce the geographic and historical background of Palmyra in the Roman era. Its critical position along the caravan routes promised its prosperity in the Syrian desert. The main part of this paper will focus on the jin discovered in a tower tomb. After a briefing of its material properties and weaving structures which confirmed its provenance from China, I shall draw emphasis to the iconography of naked figures within vine scrolls inhabited by various animals. I am going to argue that this pattern took inspiration from the classical "grape-picking Cupids" motif especially popular in the Eastern Mediterranean and Hellenistic Central Asia. Meanwhile, Chinese weavers accommodated the foreign motif with indigenous forms of mythical camels and felines. Together, they seemed to represent a picture of afterlife wonderland. Finally, the case study will lead to a discussion of changing methodologies to study ancient cultural contact, from "colonisation" to "hybridity" and lately "globalisation".

5 NAVIGATING CROSSROADS NARRATIVES IN THE ROMAN EAST THROUGH WHITE MARBLE PROVENANCE: THE STUDY OF FUNERARY MONUMENTS FROM THE STRYMON VALLEY

Anevlavi, Vasiliki (Austrian Archaeological Institute, Austrian Academy of Sciences) - Andreeva, Petya (National Archaeological Institute With Museum, Bulgarian Academy of Sciences) - Prochaska, Walter (Austrian Archaeological Institute, Austrian Academy of Sciences) - Ladstätter, Sabine (Austrian Archaeological Institute, Austrian Academy of Sciences)

The tie between extensive quarries and regional production yields a scientifically grounded framework, fostering heightened economic integration and advancing the systematic exploitation of local raw material sources. Inquiries arise on how geographic position and topography influence connected cities' pivotal roles at crossroads. Marble, as a compass, directs our exploration towards a deeper understanding of the material aspects. Geoarchaeological provenance studies reveal materials' origins, shedding light on objects, monuments, and socio-economic networks between diverse regions.

The current study examines the crucial connection between East and West through the Strymon Valley in Roman Macedonia and Thrace. It serves as a vital link, bridging the Aegean area and the Balkan hinterland. The valley's geographical position at the crossroads facilitates an in-depth exploration of this historical connection. The study's core lies in examining funerary monuments in Upper, Middle and Lower Strymon Valley regions, spanning present-day Bulgaria and Greece. A substantial array of objects, predominantly dating from the second and third century AD and crafted from white marble, undergoes comprehensive analysis. This examination encompasses petrography, stable isotopes, and chemical analysis to unravel the provenance of these artefacts. The results reveal a significant diversity in marble preferences, ranging from local to sub-regional and regional sources, highlighting the crucial role of the local marble sources in the Upper and Middle Strymon Valley in shaping the landscape of local production and economy. Notably, the utilisation of Thasian marble is confined to the lower part of the valley, and intriguingly, despite the abundance of local sources, supra-regional marble sources like Prokonnesos also make an appearance.

Study challenges trade boundaries, showing networks span regions, surpass provincial borders, and defy geographical limits. It emphasises the critical importance of an interdisciplinary approach in unravelling the complexities of ancient marble production, workshops, and socio-economic dynamics within the provinces.

6 BETWEEN THE SEA AND LAND: REGIONAL NARRATIVES ENCAPSULATING NORTHERN ALBANIAN ARCHAEOLOGY DURING THE EARLY AND MIDDLE BRONZE AGE

Mara, Anisa (University of Toronto)

The Bronze Age (BA) in Eurasia has been generally characterized as a crucial period of socioeconomic transformations. This portrayal of the BA, however, exhibits regional nuances. In the Mediterranean, these transformations are typically viewed as tripartite: a) urbanization, with major centers emerging, especially in the east; b) maritime trade; and c) a multitude of technological innovations, such as metal tool production or the adoption of the potter's wheel. There is also a distinctly 'continental' perspective on these processes, primarily in the eastern European territories, such as the Carpathian, here narratives of social change center specifically on the mobility characteristic of the Kurgan/Corded Ware/Bell Beaker phenomena.

The area under this study falls in one of the regions where these two stories meet: the western Balkans or eastern Adriatic. Positioned in this 'liminal' zone, one can adopt either a maritime and Mediterranean-oriented perspective on the BA or a more continental and Balkan-oriented one. This paper discusses the ways in which these narratives have affected our historical and current understanding of the west Balkan/ eastern Adriatic BA, and more specifically, the Early Bronze Age (EBA) and Middle Bronze Age (MBA) of one region, that of northern Albania. This analytical lens aims to provide an overarching understanding of how archaeological evidence is approached in the currents of thought that have led to a particular narrative holding sway – that of the 'Cetina phenomenon' – and what approaches are needed to redress the balance so that we are not immediately predisposed to look for inequality and trade no matter what, regardless of local patterns. My paper intends to emphasize the lifeways of local communities in northern Albania during the EBA/MBA and the extent of their interaction with the outside world to understand the composite picture of the region.

7 (RE)CENTERING THE AUGUSTAN TROPAEUM ALPIUM: A FEMINIST AND QUEER ANALYSIS OF THE 'IDEAL' FEMALE CAPTIVE

Madden, Kelsey (Institute of Classical Studies, School of Advanced Study, The University of London)

Constructed in 7/6 BCE within the Maritime Alps near Saint-Tropez, France (Gaul), the Augustan Tropaeum Alpium monument was dedicated by the Senate and people of Rome to celebrate Augustus' military achievements in Gaul. Positioned prominently, it commands attention both from land and sea, featuring an inscription on its western façade detailing the forty-five subdued "Alpine Tribes", framed by two striking friezes. These friezes depict a tropaeum, a

wooden trophy adorned with the arms of the conquered, accompanied by captive male and female figures, interpreted as stereotypical Gauls, chained at its base (Silberberg-Pierce 1986).

Within Roman conquest iconography, the portrayal of captive women serves as a potent symbol, signifying the dominance and expansion of Roman power while also implying the obliteration of 'barbarian' familial structures (Dillon 2006). Furthermore, these depictions often evoke the spectre of wartime sexual violence, exploitation, and human trafficking (Madden, in press). Notably, the depiction of these Gallic captive women does not accurately represent the multi-ethnic nature of the region (Mullen 2013). In essence, these depictions represent an "ideal captive..

Contrary to prevailing perspectives, such as those proposed by Ian Ferris (2000), which emphasise the monument's role as merely facilitating the convergence of cultural, political, and military concerns as a transitional space within the provincial road network, my examination suggests that the Tropaeum Alpium, with its gendered visual imagery, served as a fixed locus for the dissemination of Roman cultural ideals surrounding the "ideal" war-ravaged and trafficked captives while simultaneously intersecting with the lived experiences of the multi-ethnic local and regional communities who experienced such subjugation. This paper adopts a feminist and queer theoretical framework to deconstruct the bodily representation of captive women on the monument and its implications for understanding the intersecting dynamics of power and violence within the context of Roman predatory warfare in Southern Gaul.

1167 HISTORICAL ARCHAEOLOGIES OF THE COASTAL AND FLUVIAL ANTHROSPHERE ? LANDSCAPES AND STRUCTURES, COMBINING SETTLEMENT ARCHAEOLOGY AND GEOSCIENCES

Session theme: 2. Archaeological Sciences, Humanities and the Digital era: Bridging the Gaps

Session organisers: Ferenczi, Laszlo (Department of Archaeology, Charles University) - Bergamo, Martina (Ca' Foscari University of Venice) - Paiano, Jacopo (Ca' Foscari University of Venice) - van Lanen, Rowin (The Cultural Heritage Agency of the Netherlands) - Zatykó, Csilla (HUN-REN Institute of Archaeology, Research Centre for the Humanities)

Session format: Regular session

As highlighted in a recent position paper (Werther-Mehler 2021), fluvial landscapes/floodplain environments are global hotspots, particularly sensitive to socioenvironmental changes. Similarly, littoral landscapes, lagoonscapes, shallow shorelines, extensive coastal marshes, with their constantly changing morphology and different resources, proved to be particularly appealing places for human settlement and represent critical contexts for observing settlement dynamics from a diachronic perspective.

On one hand, material culture perspectives (i.e. building and settlement archaeological observations) demonstrate an interdependence between environment, as environmental variability played a fundamental role in shaping material and social structures (construction techniques, productions, infrastructures, or property systems, labour organization and the size of the respective communities). On the other hand, advances in geoarchaeology, palaeoecology, remote sensing techniques and GIS modelling provide increasingly rich views into the dynamics of these systems, and into a variety of factors (e.g. climate, geology, river morphology) influencing the strategies of human communities. Wetland landscapes constantly attracted human populations, yet their dynamic changes (in terms of population size, social organization, landscape environment) posed considerable challenges, requiring adaptation. Although in historical periods, the multicausal nature of anthropogenic forcing mechanisms is better documented, particularly the changing intensity and scale of settlement (contraction-expansion), fundamentally influencing land-cover changes, and also fluvial responses, large scale patterns are less well understood.

Our session adopts a multiperiod-approach, from pre-Roman to late medieval times, inviting papers that

- provide a regional/sub-regional perspective
- investigate "short" or "long durée" human adaptation strategies in specific landscapes
- contrast environmental "determinism" (constraints) and eco-possibilism (human adaptation)
- demonstrate the combined use of geoscientific and settlement archaeological methods to reconstruct past human activities, environmental change, crisis management-resilience strategies
- study settlement structure/distribution dynamics in relation to environmental/socio-economic factors (relevant from the point of view of wetland management)
- track responses of human communities to environmental change (flooding, erosion, other hazards).

ABSTRACTS

1 FLUVIAL ANTHROSPHERES AND THE WAY TO THE ANTHROPOCENE - GENERAL THOUGHTS AND METHODOLOGICAL APPROACHES

Werther, Lukas (Deutsches Archäologisches Institut) - Mehler, Natascha (Tübingen University, Historical Archaeology) - Schenk, Gerrit (TU Darmstadt, History of the Middle Ages) - Zielhofer, Christoph (Leipzig University, Physical Geography)

Floodplains represent a global hotspot of sensitive socio-environmental changes and early human forcing mechanisms. They are exceptionally dynamic landscapes and key areas of European cultural and natural heritage. Due to their high land-use capacity and the simultaneous necessity of land reclamation and risk minimisation, societies have radically restructured floodplains. This anthropogenic restructuring can be so significant that former floodplains are no longer recognisable as such. Parallel hydro-sedimentary and climatic processes and human impact have formed even those floodplains, which are still close to a natural state. The question therefore arises as to whether or when it is justified to understand floodplains as a "Fluvial Anthroposphere" and which socio-ecological processes have been involved in their development. This paper will present scientific goals and methodological approaches of the DFG Priority Programme (SPP) "On the Way to the Fluvial Anthroposphere", which investigates the pre-industrial floodplains in Central Europe and the fluvial societies that operated there. It is based on the key hypothesis of a pre-modern emergence of Fluvial Anthropospheres and asks when and why humans became a significant controlling factor in floodplain formation. It is committed to multidisciplinary approaches from history, archaeology, and geosciences and investigates medieval and pre-industrial floodplains and fluvial societies. As an early transformed, sociocultural highly relevant region, the Rhine, Elbe and Danube river systems form the model region for systematic comparative analyses. The paper will also discuss, how these results can contribute to the current Anthropocene debate and related boundary conditions.

2 ROMAN STRUCTURES AND OPERATIONS AROUND THE VENETIAN LAGOON: ACCESSIBILITY, CHANNEL INTERVENTIONS, AND LANDSCAPE CHANGES

Ugolini, Federico (University of Siena) - Cirigliano, Giuseppe Prospero (IMT Lucca)

During the Roman period, delta, lagoons and rivers of the Adriatic were part of a complex web of geographical, environmental, climatic and geomorphological features. Lagoon environments, and their coastal settlements and ports, such as those of Aquileia, Altino, Concordia, were integrated into networks that included several inland centers, markets and harbours in Roman Adriatic Italy. Scholars have scarcely considered research on lagoon and riverine centers in this region, and only from a limited historical perspective. Lagoon environment also poses multiple challenges to field and underwater research. This paper focuses on the changes and interventions in the environment and landscape of the Venetian Lagoon, in the territory between Altino (Altinum) and Concordia Sagittaria (Iulia Concordia), in 100 BCE - 400 CE. Through an examination of archaeological sources and remote sensing data, this research identifies the scale and extent of these lagoon and fluvial settlements and assesses accessibility and circulation within the Venetian lagoon network. By using itineraries, port structures, embankments, dykes, channel interventions, and settlements this study examines accessibility, development and connectivity of this lagoon environment in antiquity. This project strives to advance methodological approaches, such as aerial- and field-survey and remote sensing techniques to facilitate the integration of sources within the framework of landscape and maritime archaeology in the Venetian lagoon.

3 THE ADAPTATION OF ROMAN AND POST-ROMAN SITES TO LAGOON ENVIRONMENTS: THE CASES OF LIO PICCOLO AND TORCELLO ISLAND (VENICE, ITALY)

Paiano, Jacopo (Ca' Foscari University, Venice) - Bergamo, Martina (Ca' Foscari University, Venice) - Calaon, Diego (Ca' Foscari University, Venice)

The paper analyzes construction technologies, buildings' shapes, environmental entanglements, and the eco-dynamic processes in two specific Venetian area archaeological sites, Lio Piccolo and Torcello. The Roman Imperial age maritime Lio Piccolo villa (Cavallino-Treporti) reveals an intriguing juxtaposition of a traditional 'bricks-and-marble' residential section and an unconventional - at least for the Roman traditional archaeological literature - wooden warehouse. The timber structure is perfectly adapted to the humid surroundings, goods circulation, routes, and the availability of construction materials. In contrast, Torcello island, an Early Medieval maritime trade hub, exemplifies substantial infrastructural investments tailored to port requirements, involving timber, clay/mud, and selected Roman-reused construction materials. The paper analyzes the context of the labor force and technology transfer: the goal is to underscore the socioeconomic and long-term political framework that shapes these building methods techniques and, consequently, the lagoonal landscape in antiquity.

Defining the transforming relationship between humans and the waterscape is critical in the unique context of the Venice Lagoon. The complex and unstable geomorphology imposes a specific approach to understanding how distinctive features have influenced settlement dynamics and defined the ontology of the construction technologies. The Northern Venice Lagoon's recent excavations offer valuable insights into these dynamics, highlighting a diverse array of strategies employed to harness the potential of this aquatic environment, both for trade and production.

4 **TOWARDS MUD AND SHALLOW WATERS: SETTLEMENT DYNAMICS AND ADAPTATION PROCESSES IN THE VENICE LAGOON FROM ROMAN TO EARLY MIDDLE AGES**

Bergamo, Martina (Ca' Foscari University of Venice) - Paiano, Jacopo (Ca' Foscari University of Venice) - Calzon, Diego (Ca' Foscari University of Venice)

Lagoonal environments, shallow sandy coasts and fluvial deltas are peculiar places to establish human settlement, requiring specific adaptation strategies. Nevertheless, they proved to be highly attractive to past societies, preferable for various activities and dwellings. A relevant example of this attractiveness can be retraced in the Northern Lagoon of Venice between the Roman Imperial Age and the Early Middle Ages.

Being settled in Roman and pre-Roman times for productive purposes (salt production and fishery), the lagoonal suburbs of the Roman city of Altinum on the banks of the Sile River steadily grew in importance during the Late Antiquity, giving rise to new sites alongside existing ones. These shifts are intertwined with profound natural and socioeconomic modifications: the crucial changes in Veneto Roman cities and the critical environmental waterscape transformation of the coasts. Ultimately, this process led to new Early Medieval centres with a distinct commercial focus and peculiar urban fabric.

The close correlation between the sites and the intricate pattern of river branches connecting these spaces with the mainland is more than evident. However, integrating geoarchaeological and archaeological data within a digital GIS environment, encompassing both published legacy data and findings from recent archaeological investigations, provides new insights and a more faceted interpretative framework for understanding distribution dynamics and settlement evolution.

This paper presents a sub-regional overview of the entanglement between human activity with fluvial and aquatic elements. In these wetlands, the "fluvial anthroposphere" concept involves specific interactions, including the exploitation of local resources, adaptation to continuously wet conditions, and attempted control over river configuration. Fluvial axes served as connectors and water routes: they are keys to deciphering settlement transformation patterns and interpreting archaeological phenomena.

5 **LIKE A DUCK TO WATER. ROMAN BUILDING AND ENGINEERING AT THE EDGE OF THE VENETIAN LAGOON**

Delpozzo, Eleonora (Ca' Foscari University of Venice) - Sperti, Luigi (Ca' Foscari University of Venice)

The peculiar characteristics of the lagoonscape of Venice have been well known since Antiquity, as it clearly emerges from the classical sources. The area, like much of Northern Italy, is situated on an alluvial plain formed by "megafans" of the main rivers (Brenta, Piave, Tagliamento). During the 2nd century BCE, the Romans intensified their presence in the area and their relations with local elites. In this specific historical framework, usually referred to as "Romanization", the landscape underwent impactful modifications by the Romans, who had to contend with the specific problems related to this territory, rich in waterways and subject to hydrological instability. The Romanization process entailed the construction of infrastructures and buildings, such as roads and bridges to improve mobility between settlements. However, Roman engineering techniques alone could not adapt to this peculiar landscape. This paper, based on these premises, aims to present evidence from archaeological and remote sensing data that illustrates different solutions applied to overcome the geomorphological instability of this territory. Relevant case studies will be presented, primarily from settlements in the northeastern area on the edge of the Venice lagoon, such as Altinum, Opitergium and the centuriation. The main objective of this work is to emphasize the role of local communities in transmitting technical knowledge, as well as the Romans' contribution to the issue, in a peculiar historical context that fostered this dialectic - and prolific - interaction.

6 **CITIES BELOW THE WATER LINE. DUTCH ADAPTATION STRATEGIES FOR DELTAS AROUND THE WORLD.**

Kosian, Menne C. (Cultural Heritage Agency of the Netherlands (RCE)) - Van Lanen, Rowin (Cultural Heritage Agency of the Netherlands)

The Netherlands pride themselves as a unique place in the world being a strongly urbanized, low-lying delta. Especially in these times of climate change and the need for climate adaptation strategies, as well as the necessary transition in

energy production and consumption and a need for change in agricultural land-use, we tend to focus on our "unique" position in the world for tackling these problems.

The delta allowed the country to exist and bloom. Cities in the Netherlands originated from Roman and Medieval times, all on the rivers in the delta, and since almost no rivers were embanked, they had to deal with regular flooding. Not only in the cities themselves, but also on the surrounding agricultural areas necessary for feeding these cities.

The Dutch have a long tradition of water-management and -policies. One of the latest shoots of this tree is the cycle of stress tests Dutch municipalities have to perform. Part of the National Adaptation Strategy, they give an insight in possible water, draught or heat induced problems and asks a follow-up in a risk-dialogue resulting in communal policies. Since November 2022 the Dutch government made the combination of soil and water systems leading in planning for transition assignments; 'soil and water in the lead'.

The Cultural Heritage Agency of the Netherlands (RCE) have always plead for including history and heritage into his stress test analyses. This would not only shed light to former adaptation strategies, but could also provide knowledge, or even solutions for modern policies.

The knowledge obtained from these adaptation policies and the knowledge on how the Dutch dealt with them in the past is not only of national importance. Adaptive strategies like these, including the historical perspective could be helping other low-lying delta areas around the world in their adaptive strategies.

7 **LOGBOATS FINDINGS IN PO VALLEY AND THE EARLY MEDIEVAL CASE**

Lucchini, Alice (University of Zadar, Department of Archaeology)

Logboats represent a peculiar form of watercraft, nowadays long forgotten from northern Italy's naval traditions. The findings remain sealed in deposits of the bodies of water where they used to sail, while their making implied the use of trees with shapes and dimensions that are unknown in today's Po Valley environment. The presence of adequate wood resources, however, is only one of many preconditions of their construction, as the socioeconomic context has an essential role in woodland destination and management.

This contribution aims to analyse the distribution and chronology of the findings in the Po Valley diachronically and to consider what kind of variables could have facilitated the making and spreading of logboats in some periods more than others.

Ultimately, I focus on findings from the Early Medieval Period, where their presence in the plain is more outstanding than other archaeological evidence of transports. Based on studies of cargo capacities of the findings and coeval written sources, I suggest some uses for these boats along the Early Medieval Po Valley settlements, a frame of which extension, unfortunately, is still far from being understood.

8 **CHOOSING YOUR PATH WISELY: HOW THE LONG-TERM ANALYSIS OF SETTLEMENT AND FLUVIAL DYNAMICS CAN HELP TO IMPROVE HERITAGE PRESERVATION**

Van Lanen, Rowin (Cultural Heritage Agency of the Netherlands)

Despite their dynamic nature and susceptibility to natural hazards (e.g., flooding), many river and delta landscapes throughout the past have been densely populated. Accessibility to fertile soils, easily maintainable geographical boundaries, and long-distance transport networks made these areas interesting places to live regardless of their often challenging nature. The Rhine-Meuse delta in the Netherlands is a typical example of such a wetland landscape. As early as the Bronze Age (2000-800 BC) this region was densely populated and played an integral part in long-distance trade connections. Especially during the Roman (12 BC-AD 450) and early-medieval (AD 450-1050) periods the delta underwent significant cultural and environmental changes (i.e., the collapse of the limes, river avulsions, and altering flood regimes). The extent and impact of these changes and their interaction is generally unknown and difficult to untangle, but provides essential information for amongst other heritage preservation and spatial planning.

In this paper I will focus on the long-term analyses of two cultural manifestations, both strongly influenced by cultural as well as natural dynamics: settlement patterns and route networks. Based on recent research, I will demonstrate how (1) increased flooding forced settlement to progressively move to higher locations in the delta, and (2) route networks interconnecting these settlement remained relatively stable despite evident landscape changes. It will become clear that in lowlands, such as the Rhine-Meuse delta, boundary conditions are relatively sensitive to change, making these landscape eminently suited to study and untangle the complex interplay between natural and cultural dynamics. The main aim of this paper is to illustrate that precisely the dynamic nature of delta landscapes helps to develop high-resolution spatiotemporal frameworks of cultural-landscape changes, providing essential information for heritage preservation (i.e., through improving predictive modelling), spatial planning (e.g., learning from the past), and facing future challenges (e.g., climate changes).

9 INVESTIGATING HUMAN-ENVIRONMENTAL INTERACTIONS IN EXTREMELY FLAT FLUVIAL LANDSCAPES: 7,000 YEARS OF SETTLEMENT ECOLOGICAL DYNAMICS ON THE GREAT HUNGARIAN PLAIN

Gyucha, Attila (Department of Anthropology, University of Georgia, USA) - Mesterházy, Gábor (Hungarian National Museum National Archaeological Institute) - Takács, Katalin (Hungarian Institute for Soil Sciences, Centre for Agricultural Research) - Árvai, Máttyás (Hungarian Institute for Soil Sciences, Centre for Agricultural Research) - Nagy, Balázs (Department of Physical Geography, Eötvös Loránd University, Hungary) - Magyari, Enikő (Department of Environmental and Landscape Geography, Eötvös Loránd University, Hungary)

Fluvial environments are favorable landscapes for agrarian communities and, therefore, have been subject to human interventions since the advent of farming. Over the past centuries, extensive anthropogenic alterations have occurred in many of these regions worldwide, causing fundamental changes in water networks, landscape morphology, and soil attributes. These human-induced changes, coupled with natural transformations, pose a considerable challenge for archaeologists attempting to reconstruct ancient landscapes in alluvial plains and investigate past human-environmental interactions.

This paper applies a historical ecological perspective and presents a methodological approach to achieve a nuanced understanding of how different environmental factors, their combinations, and their changes influenced settlement decisions over time in extremely flat alluvial environments. Specifically, we focus on settlement dynamics as they relate to climate, hydrology, topography, and soil characteristics covering ca. 7,000 years for a 75-square-kilometer microregion within the Körös Basin on the Great Hungarian Plain. We took into account information on climatic changes, and using LIDAR data, we reconstructed the ancient river system, which underwent significant transformations due to water regulation campaigns in recent centuries. This same dataset was employed to analyze the topography in a landscape where even slight differences in elevation had a notable impact on the distinction between regularly flooded, temporarily inundated, and flood-free areas. Additionally, we studied high-resolution coring data to investigate the correlation between various soil attributes and human settlement patterns over time. Lastly, systematically collected archaeological data from surface surveys were used to gain insight into how communities, spanning from the Neolithic to the Medieval Ages, adapted to and interacted with their environment in this particular microregion.

10 EXPLORING ENVIRONMENTAL CONSTRAINTS OF MIGRATION PERIOD SETTLEMENT IN THE MUREŞ VALLEY, ROMANIA

Szente, Gergely (Hungarian National Museum (Magyar Nemzeti Múzeum)) - Daczó, Levente (Hungarian National Museum) - Dobos, Alpár (National Museum of Transylvanian History, Cluj-Napoca) - Gáll, Erwin (The Romanian Academy of Sciences, Institute of Archaeology "Vasile Pârvan") - Rácz, Zsófia (Eötvös Loránd University, Institute of Archaeology) - Cosma, Călin (Romanian Academy, Institute of Archaeology and History of Art of Cluj-Napoca)

The authors present preliminary results of archaeological topographical project focusing on the Transylvanian Basin, carried out in the framework of a project on early medieval networks, settlement, production and distribution systems (Project No. TKP2021-NKTA-24 financed by the Hungarian NRD Office). During the Avar period (7th–8th century AD), the Avar type archaeological record was concentrated in the middle section of the catchment of the River Mureş (Transylvanian Basin, Romania), where important economic resources (salt deposits) may have been exploited. We investigate patterns of long-term settlement changes between the Roman (1st–2nd c. CE) and the Árpád period (11th–13th c. CE), and more specifically the settlement network of the Avars, studying environmental parameters. In the post-Roman period, a radical settlement contraction is documented. In the Migration period and the early medieval period another settlement-contraction phase, changes in settlement intensity, and the vertical and horizontal displacement of settlements can be observed. Until the of the Árpád period, a slow recovery could be identified. The fluvial environment seems to have determined human settlement in every historical period, and different patterns of settlement could be documented in the Mureş valley and in the valleys of its tributaries. The settlement pattern was influenced by local and supra-regional road systems, and, most probably also by the two salt deposits, situated to the south of the Mureş (in Ocna Mureş, and Ocnişoara). The area of the Mureş catchment divides into different microregions, characterised by different geological and hydrological conditions, and the core area of Avar settlement (our study area) is found in a region where there were comparatively rather favourable soil conditions for agriculture. The various factors influencing settlement patterns form a complex set of conditions, which we are still in the first stages of understanding. Thus, our contribution also attempts to outline perspectives for further research.

11 DARK SOIL ON SAND DUNES AS A RESULT OF TERRAIN LEVELLING AT THE EARLY MEDIEVAL SETTLEMENT OF MIKULČICE, MORAVIA

Janovský, Martin (Department of Archaeology, Faculty of Arts, Charles University, nám. Jana Palacha 2, Prague, 116 38, CZ) - Lisá, Lenka (Institute of Geology of the Czech Academy of Sciences, Rozvojová 269, Prague, 165 00, CZ) - Hladík, Marek (Institute of Archaeology of the Academy of Sciences of the Czech Republic Brno, v.v.i., Čechyňská 363/19, Brno, 602 00, CZ)

At the early medieval Great Moravian site of Mikulčice-Valy (8th–10th century AD), a metre-thick set of anthropogenic horizons of dark colour mixed with sand from the local dunes were found during rescue archaeological excavations. Archaeologists usually consider similar finds to be cultural layers because they are full of artifacts and ecofacts. It is the question if such general interpretation is sufficient. In order to reveal the formation processes of this humus-rich horizons in detail, the physico-chemical analyses, micromorphological analysis together with archaeological interpretation were carried out. Based on micromorphological analysis, it is clear that this is not only a cultural layer, but rather a Dark Earth that is physico-chemically influenced by the formation and gradual anthropogenic mixing with sandy substrate. This substrate is local fluvial sand, which comes from the Morava River. The river and its connection with the early medieval settlement thus also played a significant role in the development of anthropogenic soils in the 8th to 10th centuries.

12 GOING WITH THE FLOW: SITE DYNAMICS, SETTLEMENT TRANSITIONS AND LAND-USE STRATEGIES IN THE KÖRÖS VALLEY, HUNGARY

Zatyko, Csilla (HUN-REN Research Centre for the Humanities, Institute of Archaeology) - Berta, Adrián (HUN-REN Research Centre for the Humanities, Institute of Archaeology) - Kovács, Bianka Gina (HUN-REN Research Centre for the Humanities, Institute of Archaeology) - Kovács, Gyöngyi (HUN-REN Research Centre for the Humanities, Institute of Archaeology) - Mesterházy, Gábor (Hungarian National Museum) - Pető, Ákos (Hungarian University of Agriculture and Life Sciences) - Saláta, Dénes (Hungarian University of Agriculture and Life Sciences)

The development of interdependence between human communities and waterscapes is not only a subject for archaeological research but a global strategic issue determining the lives of coming generations. Prior to the 19th-century river regulation works, the wetland areas along rivers in Hungarian Great Plain were large extent, environmentally sensitive territories of social and economic life. The presentation intends to contribute to a deeper understanding of how medieval (i.e. 11th–18th centuries) communities of these wetland areas adapted their settlements and land use strategies to the landscape around them by reconstructing the fluvial landscape and examining medieval settlements along the Körös River. How did medieval communities living in the investigated areas exploit the economic potential of the landscape and react to changes in hydrography or vegetation? To what extent can we see environmental reasons or rather farming, and (estate and political) historical motives behind settlement transitions? How did remains of landscape features of earlier centuries, such as the 'Csörsz Ditch' or the 'Devil's Dyke' and kurgans influence the landscape perception of medieval people? The research programme to be presented seeks the answers to these questions by interconnecting results of several disciplines and relying on historical sources, archaeological datasets of surface surveys complemented and interpreted by state-of-the-art methods of archaeological prospection and field survey analysis, remote sensing data, GIS modeling, and analyses in the fields of landscape history and hydrology.

13 THE RIVER WESCHNITZ FLUVIOSCAPE AND ITS INTERACTION WITH THE LORSCH ABBEY - AN OVERVIEW OF RESEARCH QUESTIONS

Prien, Roland (Ruprecht-Karls-Universität Heidelberg, Germany; Hessian State Office for Monuments and Sites, Archaeological Unit, Field Office Darmstadt, Germany) - Henselowsky, Felix (Institute of Geography, University of Mainz, Germany) - Hillmus, Nicolai (Institute of History, Technical University Darmstadt, Germany) - Jäger, Barbara (Institute of Geography, University of Heidelberg, Germany) - Appel, Elena (Institute of Geography, University of Mainz, Germany) - Becker, Thomas (Hessian State Office for Monuments and Sites, Archaeological Unit, Field Office Darmstadt, Germany) - Mächtle, Bertil (Institute of Geography, University of Heidelberg, Germany) - Schenk, Gerrit (Institute of History, Technical University Darmstadt, Germany) - Bubbenzer, Olaf (Institute of Geography, University of Heidelberg, Germany) - Vött, Andreas (Institute of Geography, University of Mainz, Germany)

The River Weschnitz, a 2nd order tributary of the Rhine system, has its origin in the Odenwald mountains and enters the Upper Rhine Graben at the city of Weinheim (northern Baden-Württemberg). Today's course in the Upper Rhine Graben is still partly naturally influenced by the Palaeo-Neckar fluvial system, but has been massively anthropogenically modified for most of its course since Roman times and especially in the Middle Ages and the Modern era. Decisive to these alterations is the foundation of the Lorsch Abbey in AD 764 that caused the emergence of new economic and political patterns closely tied to the river. Though the famous Codex Laureshamensis specifies that the original monastery was situated super fluvium Wisgoz its precise location remains elusive. In the High Middle Ages two

further monasteries were established within the Weschnitz floodplain. Since the Lorsch Abbey and its secular successors functioned as a cultural and economic centre for the wider surroundings, humans had to cope with the naturally high groundwater table and episodic flood events. Therefore, humans carried out river diversions, channel, dam and bridge constructions, as well as flood reduction measures. The river Weschnitz was further subject to the influence of milling, mining and tannery until the 20th century.

Within the framework of this collaborative research project, which is part of the DFG-funded Priority Programme 2361 On the Way to the Fluvial Anthroposphere, environmental historians, physical geographers and archaeologists work closely together on historical documents, maps, archaeological sites, artefacts and sedimentary archives in order to establish a base for reconstructing and modelling the Weschnitz Fluvioscape. In the first year of the project work, a wide range of research questions has been established that will be discussed in this paper based on first preliminary results.

14 MEDIEVAL COLONIZATION OF AN UPLAND LANDSCAPE IN WESTERN BOHEMIA - ENVIRONMENTAL ARCHAEOLOGICAL, HISTORICAL ECOLOGICAL AND LANDSCAPE ARCHEOLOGICAL APPROACHES

Ferenczi, Laszlo (Univerzita Karlova)

The paper focuses on the catchment of the Strela River, in the North Plzen district, in Western Bohemia, where a comprehensive GIS based evaluation of archaeological and historical topographical data has been carried out to study the landscape of a Cistercian estate (the Abbey of Plasy) and the hierarchies and dynamics of the medieval settlement network with respect to monastic colonisation, settlement expansion and subsequent contraction in the high and late medieval periods. In addition to the study of LiDAR data, which inform about agricultural and industrial uses of the now wooded (reforested) landscape zones, the soil topography and bonity have been also evaluated in relation to agricultural farming patterns and the site selection strategy of monastic farmlands. Soil geochemical and soil isotope assessments have been carried as case studies at selected manorial sites, complemented by pollen analytical studies, to understand the environmental impact in the vicinity of monastic manors. The impact of monastic management on the local hydrological conditions have been comparatively evaluated, mapping medieval and post medieval mill sites and multiple fishpond systems for the whole area of the catchment. By implementing this multi-disciplinary approach, it was possible to reflect on the historical narratives with regard to monastic (Cistercian) colonization, water management and woodland management in the medieval period, which fundamentally shaped the history of this landscape. This generally expands our knowledge on how the natural environment influenced monastic settlement strategies, particularly in the context of fluvial landscapes, which connected the relatively earlier settled Altsiedelland with marginal settlement zones.

1168 NOT ALL MEN. APPROACHING MASCULINITIES AS GENDERED IDENTITIES WITHIN THEIR SOCIAL CONTEXTS AND PRACTICES IN PREHISTORIC EUROPE

Session theme: 1. The Material Record: Current Trends and Future Directions

Session organisers: "Higuero Pliego, Antonio (Universidad de Cantabria) - Magalhães dos Santos, Juliana (2) Université Paris 1 Panthéon-Sorbonne).

Session format: Regular session

Masculinity is as social constructed, negotiated and performed as Femininity. However, it tends to be more naturalised than its "counterpart" (in a binary system thinking) due to being under-studied. This issue stems from the general lack of interest on Feminism and Gender Theory by male archaeologists, and a major focus on Femininity by the female ones. Also, a lot of the studies on masculinities have been based on the good graves found with bodies estimated as biologically males, such as weapons and personal adornment, and analysed by patriarchal values such as power, violence and social status. Thus, presenting these interpretations as neutral and forgetting the social aspects of the gender. The European Prehistory is a good context to see what have happened and the new direction these studies could take. Not only is interesting the emergence of the warriors elite (and beauty) during the Bronze Age, but also the ways of life of the Mesolithic "men", the impact of the concept on gender from the Neolithic groups that expanded into this wide region, and how the appearance of metallurgy may changed those societies.

In this session, as we aim to rethink the masculinit(ies)y in Prehistoric Europe from a feminist and constructivist approach. First, interpreting the past: How can the masculinit(ies)y be identified in the archaeological record? Which signs and material culture should we look for? And second, studying the masculinit(ies) within the(ir) specific context(s): how was it socially constructed and performed? What kind of impact had in the daily life of those groups? Which values could it be associated with? We welcome different contributions: from case studies, reinterpretations of previous works, new theoretical frameworks. The topics may include: analysis on skeletal remains (osteobiography,

isotopical analysis, palaeopathology...), grave goods (e.g. weapons), monuments (mounds, megaliths...) and graphical expressions, such as funerary stelae.

ABSTRACTS

1 "BROTHERS IN ARMS": THE SIGNIFICANCE OF THE SWORD OF RUCHANO (CANTABRIA) IN THE CONSTRUCTION OF MASCULINITY DURING THE BRONZE AGE

Higuero Pliego, Antonio (Universidad de Cantabria)

Since its discovery, the sword of Ruchano, found in 1975 in the cave with the same name, has been labelled as a "very particular finding". However, its importance has been overlooked in a region where most of the studies have been focused in the hunter-gatherer societies. Without a clear archaeological context, and since the first publication, the typology pointed to an argaric origin, and the location in a flooded room within the cave, was interpreted as an "offering to the waters". Recent analysis (2022) of the lead isotopes confirmed the former point.

An argaric sword in the cantabrian region not only provides valuable information about the trading networks during the Bronze Age in the Iberian peninsula, both for the final product and its components, such as the tin. In the dawn of the warrior societies, it should be understood within the semantics of that specific kind of masculinity, not only as a good of status, prestige and violence. Taking into account more evidences, such as other swords from the same region mixing foreign models with local manufacture, as well as armed and individualised human depictions in rock carvings, suggests that the groups in the cantabrian region were completely integrated in the European warrior imaginary. Although more research is still necessary, it is safe to point that the same processes of individualisation and social hierarchisation took place there. Even more, the mixing of goods from different contexts in a close geographical range, such as the argaric sword of Ruchano (Mediterranean) and the cauldron of Cabarceno (Atlantic), allow us to consider the area as a pivotal point in the dissemination of codes and signs about how to be a man.

2 SIZE AND ATTRIBUTES AT THE DAWN OF SOCIAL PORTRAIT: THE CASE OF THE CANTABRIAN MOUNTAINS, SPAIN

Teira-Mayolini, Luis (Instituto Internacional de Investigaciones Prehistóricas de Cantabria)

In the north of the Iberian Peninsula, the term "idol" or "idoliform" has traditionally been used to identify a group of large anthropomorphic stelae and engravings, chronologically located between the second half of the third millennium and the beginning of the second millennium BC. Unlike this interpretation with a religious background, we consider that these examples identify prominent figures within a human group, in a hierarchical relationship model. In this paper we analyse two sets of anthropomorphs of significant graphic personality and parallel processes in the Cantabrian mountain range which, nevertheless, communicate a similar social message: the emergence of an individualised identity by the male of the group, in which weaponry, together with its representation, played an important role in the (pre) historical development. Even more, considering other contemporary European warrior elites as well as other material culture, it is clear that the Cantabrian region was embedded into a larger social context.

Both groups use a small but common number of graphic motifs that seem to convey attributes of authority and power. In both groups, we observed a play of sizes between similar figures, used as a value discriminant. We also observed the exclusive presence of weapons and dual or twinned representations, in which a gender proposition cannot be ruled out. In short, both use narrative resources which, in a more careful elaboration, we will be able to observe in later archaeological contexts of European or Asian protohistory, in what seems to be the beginnings of social portrait.

However, the different distribution of their elements and the personality of their graphic solutions tell us of two cultural traditions developed in parallel on either side of the Cantabrian mountain range.

3 BEYOND DICHOTOMIES: RETHINKING THE SYMBOLISM AND GENDER ASSOCIATIONS OF SCANDINAVIAN BATTLE AXES OF THE BATTLE AXE CULTURE

Roy, Amber (Stockholm University)
